2025 Aquatic Effects Monitoring Program Interpretive Report

March 2026

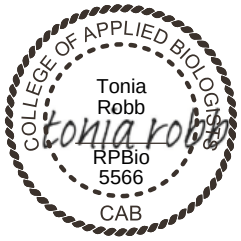
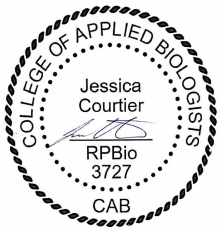
As required by Condition 4.6.5 of *Environmental Management Act* Permit 110652, A permittee (Blackwater Gold LTD.) must cause a Qualified Professional (QP) to prepare an Aquatic Effects Monitoring Program (AEMP) Interpretive Report for the year in which the AEMP was required to be conducted. The AEMP was prepared and implemented by QPs, including those shown below.
A QP is a person who has training, experience, and expertise in a discipline relevant to the field of practice set out in the condition, is registered with a professional organization enabled under an Act who must follow a code of ethics issued by the professional organization, perform her or his duties in the public interest, and can be subject to disciplinary action by the organization.





Tonia Robb, PhD, PBiol, R.P.Bio
Principal Technical Consultant
Sections 1 to 6, 11, 12 and Sections 7.3.2 and 7.4

Jessica Courtier, BSc, R.P.Bio
Triton Environmental Consultants Ltd.
Section 7 (except for 7.3.2 and 7.4) and Sections 8 to 10

ERM Consultants Canada Ltd.
1100 Melville St #1000
Vancouver, British Columbia

PLAIN LANGUAGE SUMMARY 1

SURFACE WATER QUALITY 4
CHRONIC TOXICITY 6
SEDIMENT QUALITY 6
PERIPHYTON COMMUNITY 7
BENTHIC INVERTEBRATE COMMUNITY 8
FISH COMMUNITY INVENTORY AND FISH TISSUE METALS 9
KOKANEE SPAWNING SURVEY 9
KOKANEE FRY SPRING OUTMIGRATION SURVEY 10
RAINBOW TROUT SPAWNING SURVEY 10
RECOMMENDATIONS 10

1. INTRODUCTION 1-1

1.1 MINE WATER MANAGEMENT 1-1
1.2 REGULATORY FRAMEWORK 1-4
1.3 PURPOSE AND OBJECTIVES 1-12
1.4 LINKAGES TO OTHER MONITORING PROGRAMS 1-12
1.5 2025 MINE ACTIVITIES 1-13
1.5.1 Operations and Construction 1-13
1.5.2 Water Management Current Conditions 1-14
1.5.3 Discharges to the Receiving Environment 1-15
1.6 WILDFIRES 1-15
1.7 SAMPLING PROGRAM 1-18
1.7.1 Study Area 1-18
1.7.2 Components Included in the Aquatic Effects Monitoring Program 1-20
1.7.3 Sampling Sites and Frequency 1-21
1.7.4 Special Study—Hydrocarbons 1-34
1.8 ADAPTIVE MANAGEMENT 1-35

2. SURFACE WATER QUALITY 2-1

2.1 MEASUREMENT AND ASSESSMENT ENDPOINTS 2-1
2.2 SAMPLING SITES AND METHODS 2-1
2.2.1 Field Methods 2-1
2.2.2 Laboratory Methods 2-2
2.2.3 Quality Assurance/Quality Control 2-3
2.2.4 Data Analysis 2-3
2.3 RESULTS AND DISCUSSION 2-14
2.3.1 Study Question 1—Comparison to Baseline 2-15
2.3.2 Study Question 2—Comparison to Model Predictions 2-68
2.3.3 Study Question 3—Comparison to Water Quality Guidelines, Science-Based Environmental Benchmarks, and Standards 2-71

2.4 WATER QUALITY RESPONSE FRAMEWORK 2-83
2.4.1 Methods 2-83
2.4.2 Results 2-83
2.5 SUMMARY AND RECOMMENDATIONS 2-90
3. CHRONIC TOXICITY TESTING 3-1
3.1 MEASUREMENT AND ASSESSMENT ENDPOINTS 3-1
3.2 SAMPLING SITES AND METHODS 3-1
3.2.1 Field Methods 3-1
3.2.2 Laboratory Methods 3-1
3.2.3 Data Analysis 3-2
3.2.4 Quality Assurance/Quality Control 3-2
3.3 RESULTS AND DISCUSSION 3-3
3.3.1 Fathead Minnow Survival and Biomass 3-3
3.3.2 *Ceriodaphnia dubia* Survival and Reproduction 3-3
3.3.3 *Pseudokirchneriella subcapitata* 72-hour Growth Inhibition 3-3
3.3.4 *Lemna minor* 7-day Growth Inhibition 3-4
3.3.5 Quality Assurance/Quality Control 3-4
3.4 SUMMARY AND RECOMMENDATIONS 3-4
4. SEDIMENT QUALITY 4-1
4.1 MEASUREMENT ASSESSMENT ENDPOINTS 4-1
4.2 SAMPLING SITES AND METHODS 4-1
4.2.1 Field Methods 4-1
4.2.2 Laboratory Methods 4-2
4.2.3 Quality Assurance/Quality Control 4-2
4.2.4 Data Analysis 4-2
4.2.5 Special Study—Hydrocarbons 4-5
4.3 RESULTS AND DISCUSSION 4-7
4.3.1 Study Question 1—Comparison to Baseline 4-7
4.3.2 Study Question 3—Comparison to Sediment Quality Guidelines 4-10
4.3.3 Special Study—Hydrocarbons 4-21
4.4 SEDIMENT QUALITY RESPONSE FRAMEWORK 4-22
4.4.1 Methods 4-22
4.4.2 Results 4-22
4.5 SUMMARY AND RECOMMENDATIONS 4-28
5. AQUATIC PRIMARY PRODUCERS 5-1
5.1 MEASUREMENT ASSESSMENT ENDPOINTS 5-1
5.2 SAMPLING SITES AND METHODS 5-1
5.2.1 Field Methods 5-1
5.2.2 Laboratory Methods 5-2
5.2.3 Quality Assurance/Quality Control 5-2
5.2.4 Data Analysis 5-3
5.3 RESULTS AND DISCUSSION 5-5
5.3.1 Study Question 1—Periphyton Biomass Comparison to Baseline 5-5
5.3.2 Study Question 3—Periphyton Biomass Comparison to Water Quality Guidelines 5-7
5.3.3 Study Question 1—Periphyton Community Composition Metrics Comparison to Baseline Ranges 5-7

5.4 PERIPHYTON AND NUTRIENT RESPONSE FRAMEWORK 5-9
5.4.1 Methods 5-9
5.4.2 Results 5-13
5.5 SUMMARY AND RECOMMENDATIONS 5-15
6. AQUATIC INVERTEBRATES 6-1
6.1 MEASUREMENT ASSESSMENT ENDPOINTS 6-1
6.2 SAMPLING SITES AND METHODS 6-1
6.2.1 Field Methods 6-2
6.2.2 Laboratory Methods 6-2
6.2.3 Data Analysis 6-4
6.3 RESULTS AND DISCUSSION 6-7
6.3.1 Study Question 1—Abundance and Community Composition Metrics Comparison to Reference Condition 6-8
6.3.2 Study Question 1—Tissue Metal Comparison to Baseline 6-28
6.3.3 Study Question 3—Tissue Metal Comparison to Guidelines 6-41
6.3.4 Quality Assurance/Quality Control 6-42
6.4 AQUATIC INVERTEBRATE RESPONSE FRAMEWORK 6-42
6.4.1 Methods 6-42
6.4.2 Results 6-43
6.5 SUMMARY AND RECOMMENDATIONS 6-45
7. FISH COMMUNITY INVENTORY AND FISH TISSUE METALS 7-1
7.1 MEASUREMENT AND ASSESSMENT ENDPOINTS 7-1
7.2 SAMPLING SITES AND METHODS 7-1
7.2.1 Field Methods 7-4
7.2.2 Laboratory Analysis 7-5
7.2.3 Quality Assurance/Quality Control 7-5
7.2.4 Data Analysis 7-6
7.2.5 Exceptions to Methods 7-9
7.3 RESULTS AND DISCUSSION 7-10
7.3.1 Fish Community Inventory 7-10
7.3.2 Fish Tissue Metals 7-23
7.4 FISH TISSUE RESPONSE FRAMEWORK 7-33
7.4.1 Methods 7-33
7.4.2 Results 7-34
7.5 SUMMARY AND RECOMMENDATIONS 7-34
8. KOKANEE SUMMER SPAWNING SURVEY 8-1
8.1 MEASUREMENT AND ASSESSMENT ENDPOINTS 8-1
8.2 SAMPLING SITES AND METHODS 8-1
8.2.1 Field Methods 8-4
8.2.2 Laboratory Analysis 8-5
8.2.3 Quality Assurance/Quality Control 8-5
8.2.4 Data Analysis 8-5
8.2.5 Exceptions to Methods 8-7
8.3 RESULTS AND DISCUSSION 8-7
8.3.1 Kokanee Spawner and Redd Density 8-8
8.3.2 Escapement Estimates—Davidson Creek and Creek 661 8-12

8.3.3 Length at Maturity 8-12
8.3.4 Substrate Composition 8-13
8.3.5 Mesohabitat 8-15
8.4 SUMMARY AND RECOMMENDATIONS 8-16
9. KOKANEE FRY SPRING OUTMIGRATION SURVEY 9-1
9.1 MEASUREMENT AND ASSESSMENT ENDPOINTS 9-1
9.2 SAMPLING SITES AND METHODS 9-1
9.2.1 Field Methods 9-3
9.2.2 Laboratory Analysis 9-4
9.2.3 Data Analysis 9-4
9.2.4 Exceptions to Methods 9-6
9.3 RESULTS AND DISCUSSION 9-6
9.3.1 Abundance 9-7
9.3.2 Condition 9-8
9.3.3 Egg-to-Fry Survival 9-10
9.4 SUMMARY AND RECOMMENDATIONS 9-10
10. RAINBOW TROUT SPRING SPAWNING SURVEY 10-1
10.1 MEASUREMENT AND ASSESSMENT ENDPOINTS 10-1
10.2 SAMPLING SITES AND METHODS 10-1
10.2.1 Field Methods 10-3
10.2.2 Laboratory Analysis 10-3
10.2.3 Quality Assurance/Quality Control 10-3
10.2.4 Data Analysis 10-3
10.3 RESULTS AND DISCUSSION 10-5
10.3.1 Abundance 10-6
10.3.2 Population Structure 10-7
10.3.3 Condition 10-9
10.4 SUMMARY AND RECOMMENDATIONS 10-12
11. AQUATIC EFFECTS MONITORING PROGRAM SUMMARY AND RECOMMENDATIONS 11-1
12. PLANNED AQUATIC EFFECTS MONITORING FOR 2026 12-1

PLAIN LANGUAGE SUMMARY

The Aquatic Effects Monitoring Program (AEMP) was developed to provide information on the streams and lakes downstream of the Blackwater Mine (the Mine; Figure 1). The AEMP was designed to achieve the following objectives for the period of Construction and Operations:

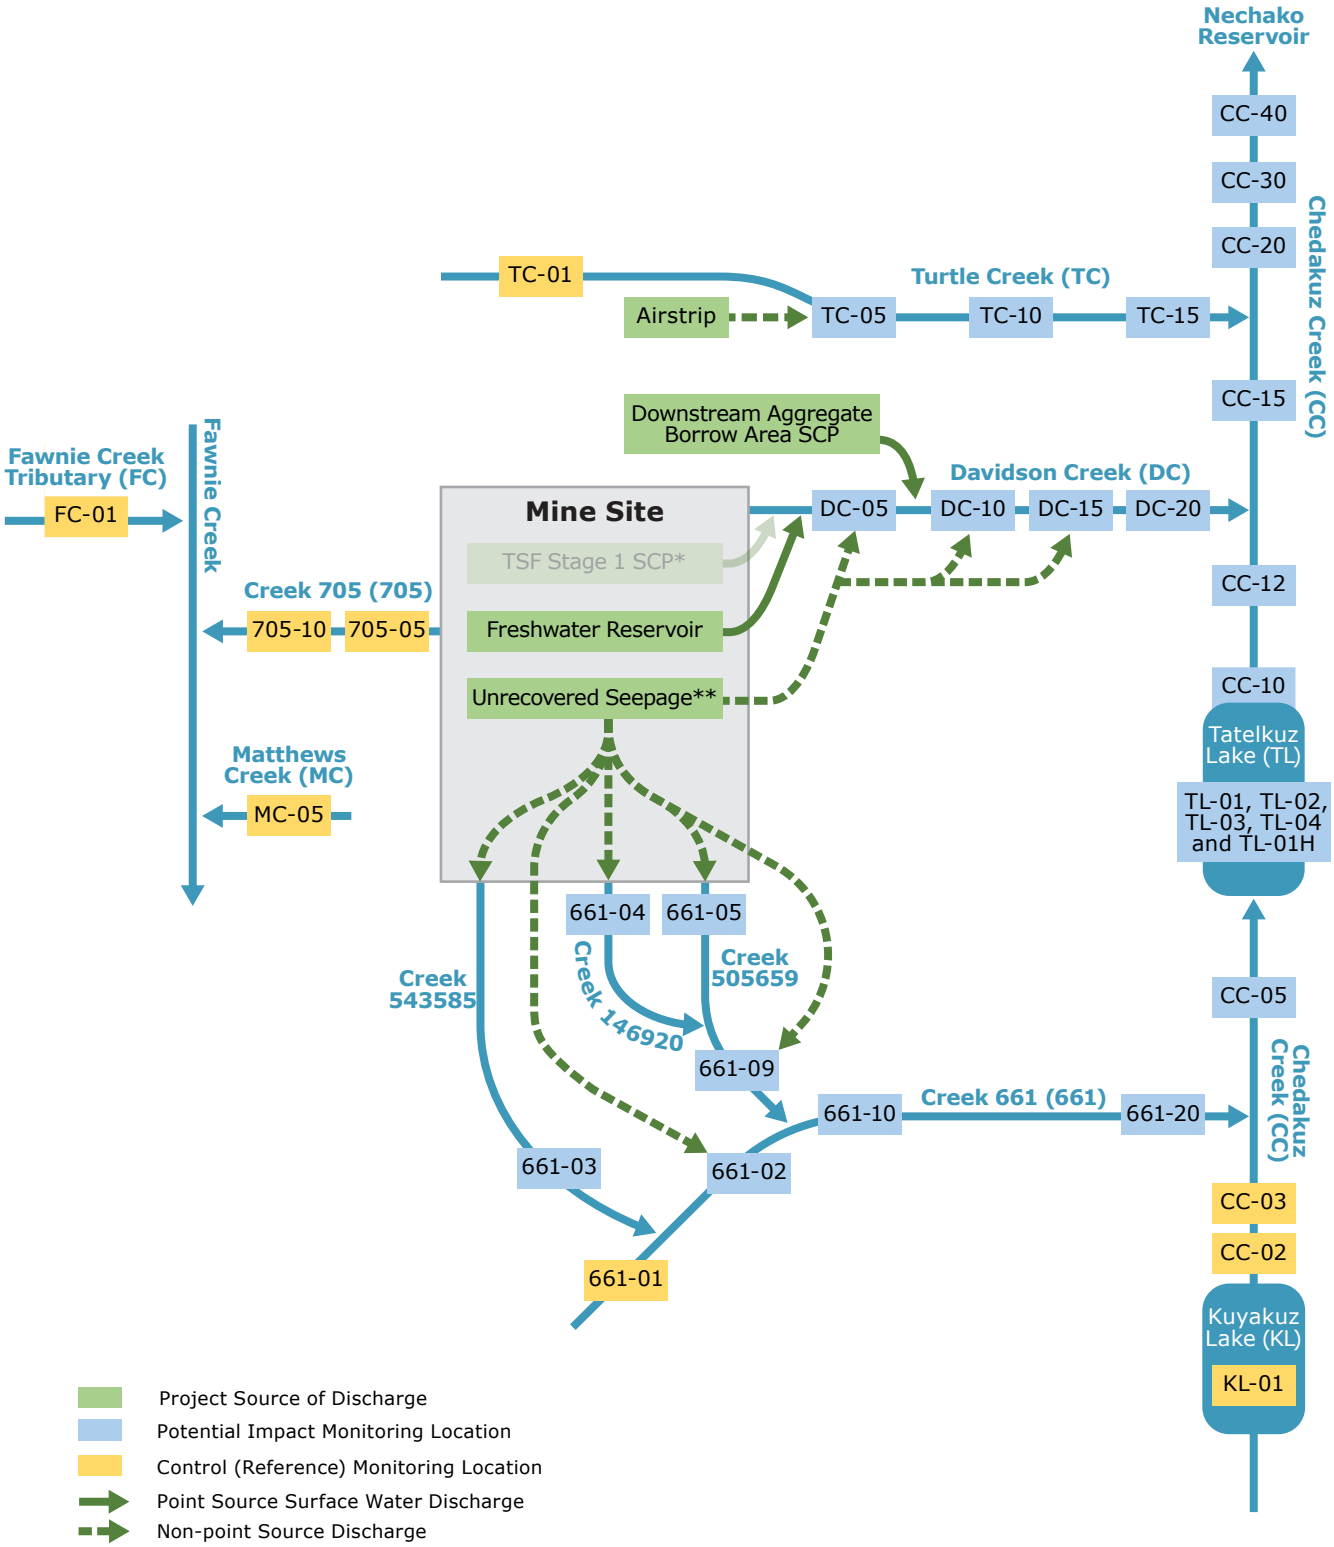
- Detect Mine-related effects on the aquatic ecosystem components – surface water quality, sediment quality, periphyton (one-celled plants that attach to rocks in streams), benthic invertebrates (organisms that live on or in the bottom sediments of rivers and streams), and fish.
- Confirm water quality predictions.
- Meet permit and regulatory requirements for effluent quality and quality streams and lakes downstream of the Mine.
- Assess the performance of mitigation (actions that reduce the amount of potential harm to aquatic ecosystem components) and management measures.
- Provide the necessary feedback and information for the adaptive management ("learning by doing") of potential Mine-related effects.
- Adaptive management establishes monitoring programs to determine if management strategies are effective and to predict unforeseen effects. The results of the monitoring programs are used to develop additional or modify mitigation measures to avoid Mine-related effects on the aquatic ecosystem components. The adaptive management framework for AEMP components (surface water quality, sediment quality, periphyton and nutrients, benthic invertebrates, and fish tissue metals) was evaluated for the construction and operations period (October 2022 to December 2025). This framework is intended to provide an early-warning system such that there is sufficient time to prevent adverse effects on water quality in streams downstream of the Mine. Numeric Performance Metrics (NPM; Trigger for Action) are provided for four action levels of the adaptive management framework- "none", "low", "medium", and "high" (Figure 2).

The AEMP includes monitoring in Davidson Creek, Creek 661, Chedakuz Creek, Turtle Creek, and Tatelkuz Lake, with corresponding control sites in Creek 705, Fawnie Creek, and Kuyakuz Lake (Figure 1).

No Mine effluent was discharged to the receiving environment in 2025. Mine effluent was pumped to the mill as make-up water to support production. However, diverted non-contact water was conveyed to the former Davidson Creek upstream of the receiving environment. The following Mine-related events were also reported with the potential to affect the streams downstream of the Mine:

- An ore stockpile dust event in Q1 of 2025;
- Water with high suspended solids was released into Davidson Creek following an Erosion and Sediment Control failure upstream; and
- Unrecovered seepage from the Tailings Storage Facility (TSF) pond (TSF C Pond).

FIGURE 1 CONCEPTUAL FLOW DIAGRAM OF BLACKWATER MINE DISCHARGES AND AQUATIC EFFECTS MONITORING PROGRAM MONITORING LOCATIONS



Notes: Flow diagram representative of Construction and Operations phases and relative distances are not to scale (i.e., the figure is conceptual).
TSF = Tailings Storage Facility; SCP = sediment control pond.
**TSF Stage 1 SCP was present and discharging during Construction phase only.*
***Unrecovered seepage may be from TSF C, Plant Site, or Camp Site.*

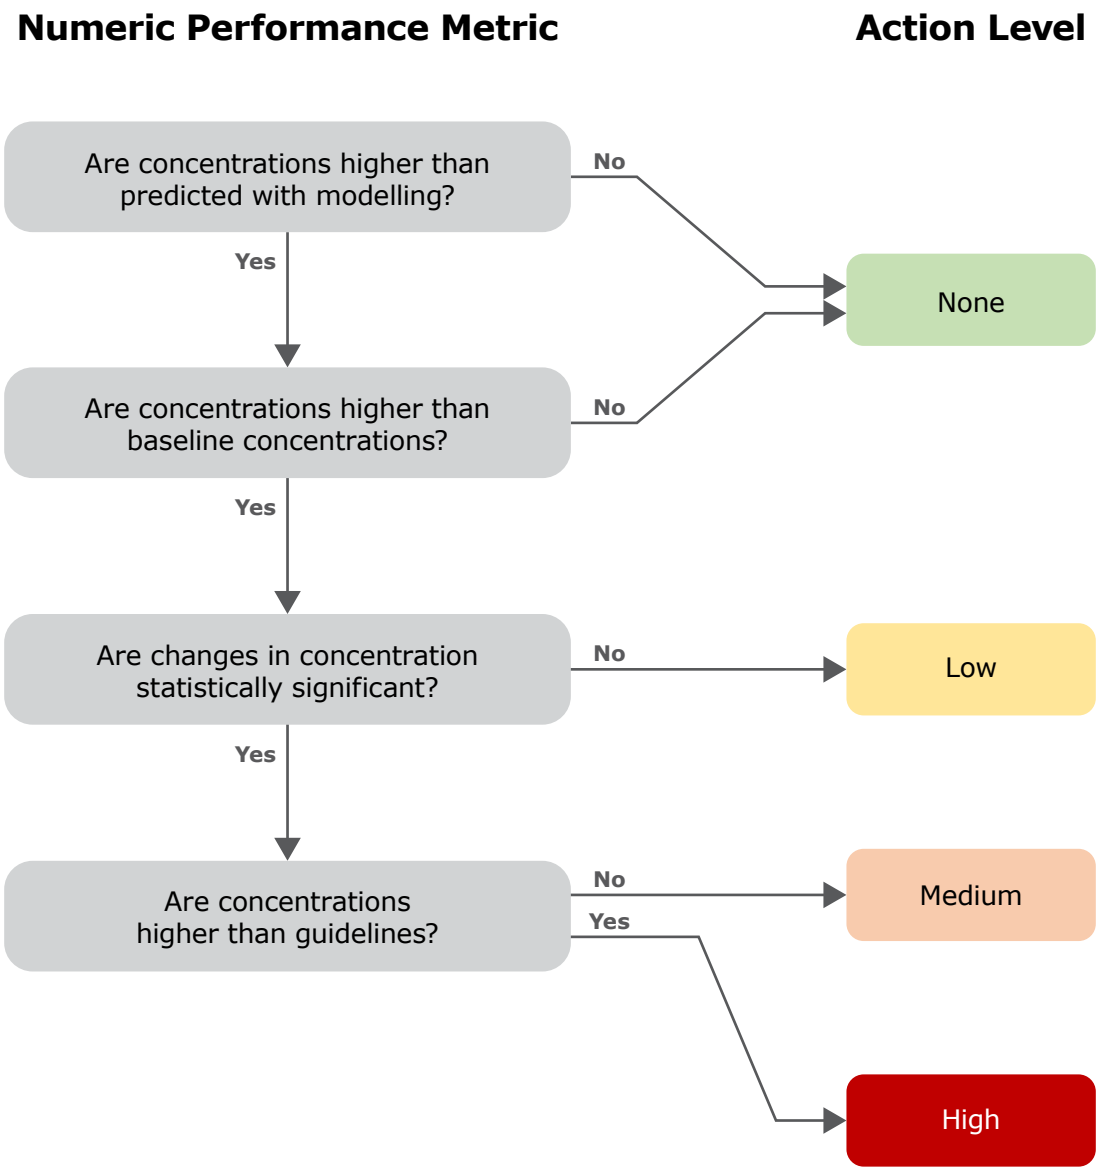
FIGURE 2 FLOW DIAGRAM OF NUMERIC PERFORMANCE METRICS AND ACTION LEVELS



SURFACE WATER QUALITY

Assessment endpoints:

- *Comparison to baseline water quality and model predictions*
- *Statistical analysis*
- *Comparison to water quality guidelines for the protection of aquatic life (WQG-AL), Science-Based Environmental Benchmarks (SBEBs), and proposed Yinka Dene Water Law (YDWL) water quality standards*

Davidson Creek—Surface water quality is monitored at sites DC-05, DC-10, DC-15, and DC-20 within the Davidson Creek Watershed (Figure 1).

The 2025 water quality at Davidson Creek sites indicated that most concentrations were similar or greater than baseline years and below levels of concern. However, there were parameters that were greater than baseline and concentrations predicted by the water quality model in two or more consecutive months: chloride, total arsenic, total copper, and total lead. Parameters with concentrations identified as Mine-related significant increases from baseline concentrations (determined by statistical analysis) were total aluminum, arsenic (DC-05), barium, iron (DC-10 and DC-15), and uranium. Parameter concentrations above WQG-ALs at Davidson Creek sites were aluminum, cadmium, cobalt, iron, manganese, and zinc. The dissolved aluminum SBEB and dissolved manganese YDWL standard were also exceeded at one or more sites and/or months. Except for cobalt, the level of exceedance and the number of months exceedances were observed did not suggest there would be effects to aquatic life.

Graphical analysis indicates concentrations of parameters that have increased when compared to baseline and evaluated as meeting a "low" or "medium" action level (Figure 2). These increases were likely caused by ash, and metal-containing particles washing into Davidson Creek after the 2023 wildfire. This material may have entered the creek directly, through runoff, or through water diverted from the area. The release of water with high suspended solids to Davidson Creek, and tree-clearing activities near the upper Davidson Creek also likely affected water quality. A "high" action level (Figure 2) was met for total iron (DC-05) however concentrations were not at levels of concern and not likely related to 2024 Mine activities. Dissolved cobalt (DC-05, DC-10, DC-15) was considered to meet the "high" action level because the 2025 concentrations were higher than baseline concentrations and WQG-AL exceedances were observed in the same months. Graphical analysis indicates dissolved cobalt concentrations at Davidson Creek sites are likely associated with unrecovered seepage from the TSF C which was confirmed based on the groundwater monitoring results. BW Gold has implemented plans to complete mitigations to address the unrecovered seepage from the TSF C to Davidson Creek and continues to monitor the effectiveness of these actions. These mitigation measures are expected to positively impact water quality in future years.

Creek 661—Surface water quality monitoring is completed in Creek 661 upstream of the Mine influence (661-01), and downstream of the Mine site (661-03, 661-04, 661-05, 661-10, and 661-20) where unrecovered seepage from the Plant Site or Camp Site may enter during construction activities (Figure 1). The 2025 water quality at Creek 661 sites were typically similar

or greater than baseline concentrations and concentrations were below levels of concern. Parameters that exceeded WQG-Als at one or more sites/months were aluminum, arsenic, cadmium, iron, mercury, and zinc however, the level of exceedance and frequency of exceedances did not suggest there would be effects to aquatic life. Graphical analysis indicated that most metals (total arsenic, barium, beryllium, cadmium, chromium, cobalt, copper, lead, manganese, and uranium and dissolved manganese, and zinc) that were elevated at sites 661-04, 661-05 and 661-10 during Q1 of 2025 were as a result of the 2025 construction activities and overland flow through the 2023 and 2024 fire-impacted areas around the Creek 661 tributaries located within the Mine site. Parameters meeting a "medium" action level (Figure 2) with a significant increase when compared to baseline concentrations were total arsenic (661-04 and 661-05), total barium (661-04 and 661-05), total uranium (661-03, 661-04, 661-05, and 661-10), and dissolved zinc (661-04). Elevated total and dissolved copper, total and dissolved cadmium, and total and dissolved zinc were likely associated with dust or particle erosion following the ore stockpile dust event. BW Gold initiated mitigation measures in May 2025 in response to the dust event and water quality at Creek 661 sites in Q3 and Q4 was like baseline years indicating the effect was not persistent through 2025 and not likely to affect aquatic life during the highest period of productivity in late August/early September. A "high" action level (Figure 2) was met for total aluminum (661-04, 661-05, and 661-10) and was most likely associated with 2025 construction activities and overland flow through the 2023 and 2024 fire-impacted areas around the Creek 661 tributaries located within the Mine site. Aluminum concentrations were similar to baseline later in the season therefore no aquatic effects to aquatic life were expected.

Chedakuz Creek—Surface water quality monitoring is completed in Chedakuz Creek upstream of Tatelkuz Lake (CC-03 and CC-05), downstream of Tatelkuz Lake (CC-10), and downstream of the confluence with Davidson Creek (CC-15, CC-20, CC-30, and CC-40; Figure 1). At Chedakuz Creek sites downstream of the Davidson Creek confluence there were exceedances of the total aluminum and dissolved iron WQG-AL. The YDWL standards were exceeded for pH, and dissolved manganese at site CC-15. The frequency and level of exceedances of WQG-AL and YDWL standards suggest exceedances are not related to Mine activities and no effects to aquatic life are expected. The 2025 water quality at Chedakuz Creek sites were typically similar or greater than baseline concentrations that were below levels of concern. Significant increases from baseline (determined by statistical analysis) in pH, turbidity, sulphate, total ammonia-N, total aluminum, total barium, total iron, total and dissolved manganese, and total uranium tended to be at Chedakuz Creek sites downstream of the confluence with Davidson Creek (CC-15, CC-20, and CC-40 but not CC-30). It was concluded that greater concentrations of turbidity, total aluminum, and total barium at sites CC-15 and CC 20 may be related to 2024 and 2025 Mine activities (i.e., upstream of DC-20). However, it was concluded that the increasing concentrations at CC-40 are likely related to the anthropogenic sources that may contribute to Chedakuz Creek water quality and at site DC-20 (e.g., forest harvesting activities, road/trail networks, cattle grazing). Mitigation in response to Mine-related changes in water quality identified in Davidson Creek are expected to also address Mine-related increases in Chedakuz Creek.

Turtle Creek—Turtle Creek sites (TC-05, TC-10, and TC-15) are in the watershed where the Mine airstrip would be located therefore an analysis of Mine-related effects was not completed for Turtle Creek sites because the airstrip has not been constructed.

Tatelkuz Lake—Tatelkuz Lake is monitored during both the open-water and under-ice seasons at TL-01 and within the littoral zone (the portion of the lake that is close to shore) at sites TL-02, TL-03, and TL-04 (Figure 1). Both lakes exhibited similar water quality and lakes exhibited differences with depth (i.e., greater total phosphorus concentrations in the deepest layer). Total and dissolved metals were low among all lake sites and typically less than detection at all depths sampled. The results of surface water quality monitoring in lakes indicated no Mine-related effects in Tatelkuz Lake.

CHRONIC TOXICITY

Assessment endpoint:

- *Calculation of a lethal concentration, effective concentration, or inhibition concentration*

Chronic toxicity testing was completed at four AEMP sites (2 impact and 2 control sites) to understand the potential effects on aquatic organism over the long-term. Test species were larval fish, an aquatic plant, an invertebrate, and green algae (representing species that are found in AEMP streams). The measurement for the tests was dependent on the test species - plant and algae growth, fish larvae ability to survive and grow, and invertebrate ability to survive and reproduce. The toxicity testing results indicated that there are no effects on plant and algae growth, or fish larvae and invertebrate survival. However, water quality at streams sites (DC-05 and 661-10) potentially affected by the 2025 Mine activities did have some limited effects on invertebrate reproduction.

SEDIMENT QUALITY

Assessment endpoints:

- *Comparison to baseline*
- *Statistical analysis*
- *Comparison to sediment quality guidelines for the protection of aquatic life (SQG-AL)*

Sediment quality was assessed at Davidson Creek sites (DC-05 and DC-15), Creek 661 sites (661-01, 661-05, and 661-10) for potential Mine-related effects (Figure 1). Sediment samples showed some increases in metals such as arsenic, cadmium, copper, lead, and zinc at downstream sites in Davidson Creek and Creek 661. These increases were consistent with natural enrichment or wildfire-related run-off in addition to the 2025 Mine activities.

Sediment quality was assessed against the sediment quality Response Framework (Figure 2). A “high” action level was exceeded for arsenic (DC-05 and DC-15), cadmium (DC-05, DC-15, 661-10), and zinc (DC-05, DC-15, 661-05, and 661-10). The elevated arsenic, cadmium, and zinc sediment concentrations at DC-05 and DC-15 are attributed to construction and operational activities since 2024. The elevated cadmium and zinc sediment concentrations at Creek 661 sites are attributed to the wildfires in addition to the ore stockpile dust event that occurred in Q1 of 2025. Although sediment metal concentrations were greater than SQG-AL in 2025, the likelihood of adverse effects to aquatic life is low based on the overall level of exceedance remaining low

(i.e., less than 5 times the guideline) that was confirmed with the observation of no significant alterations to the benthic communities and tissue metal concentrations in 2025.

Continued erosion and sediment control mitigations and dust mitigations implemented or planned to be implemented because of the dust event will continue to be completed through the Operations period. Runoff management and erosion and sediment control mitigations in response to turbid water entering Davidson Creek (either as unauthorized discharges or following exceedances of permit limits) will continue to mitigate future "high" action level exceedances.

Sediment polycyclic aromatic hydrocarbon (PAH) concentrations were also tested at sites DC-05 and DC-15 in Davidson Creek, sites 661-01, 661-05, and 661-10 in Creek 661, site TC-05 in Turtle Creek, and regional control site, 705-05. All measured sediment PAH concentrations were less than the detection limit (i.e., too low to measure), indicating naturally low concentrations of PAHs in the Mine area.

PERIPHYTON COMMUNITY

Assessment endpoints:

- *Comparison to baseline*
- *Statistical analysis*
- *Comparison to WQG-AL*

Periphyton (algae) community characteristics (growth, density, community composition, and the relative number of the types of species) was assessed at Davidson Creek sites (DC-05 and DC-15), Creek 661 sites (661-01, 661-05, and 661-10) for potential Mine-related effects (Figure 1). The 2025 periphyton communities did not indicate a significant change from baseline at impact sites in Davidson Creek and Creek 661. However, evaluation of periphyton growth indicated the 2025 concentrations are changing from baseline concentrations but are below levels of concern. The increase periphyton growth may be related to the increase in nutrients (total phosphorus) however sampling in 2025 also took place later in September than in previous years. Thus, the light conditions were likely different and periphyton may have had longer to grow, resulting in higher biomass in 2025 compared to baseline years. In addition, periphyton growth was lower than the WQG-AL, which shows that nutrient enrichment (eutrophication) is not occurring at either the impact or control sites.

Periphyton biomass and nutrients were assessed against the periphyton and nutrient Response Framework. Periphyton growth increased at the Davidson Creek and Creek 661 sites, triggering a "medium" action level (Figure 2). Most nitrogen parameters met the "none" action level at both sites, except for total ammonia at site 661-10, which met the "medium" action level. Total phosphorus at the Creek 661 sites was higher than predicted and higher than baseline levels, but this was due to short-term increases in August and September 2025 that did not continue. As a result, no changes to the current mitigation measures are required. Like the water-quality changes observed in 2025, the nutrient changes (mainly total phosphorus) were likely related to the Mine activities, thus the same mitigation measures used for water quality also apply to nutrients.

BENTHIC INVERTEBRATE COMMUNITY

Assessment endpoints:

- *Comparison to reference condition*
- *Comparison to baseline*
- *Statistical analysis*
- *Comparison of tissue metals to guidelines.*

Several benthic invertebrate community characteristics were calculated for each of the monitored Davidson Creek sites (DC-05 and DC-15), Creek 661 sites (661-01, 661-05, and 661-10) including number, community composition, and relative number of species within the community. The metrics were calculated for both the entire community and the more sensitive communities that includes mayflies, stoneflies, and caddisflies. No Mine-related effects were detected for the whole community or the sensitive species. The similarity of the benthic communities at the AEMP sites to a reference database were also calculated and the results suggested that communities downstream of construction activities were in good condition (i.e., like the reference communities) or within the range of natural variability. Another measure of benthic community health was to examine how similar their benthic invertebrate community compositions were based on habitat similarities to reference database sites. This classification was similar through time from baseline (2017 to 2022) to construction and operations or diverged slightly from reference over time (e.g., moving from "similar to reference" category to a "mildly divergent" category). The change at both impact and control sites over time suggests no Mine related impacts to benthic invertebrate communities assessed in 2025.

Concentrations of metals in benthic invertebrate tissue were generally similar to or greater than baseline, with higher concentrations at Creek 661 consistent with historical patterns. Mercury and selenium tissue concentrations were below guideline at all sites except DC-05, where mercury was slightly higher than the guideline. Statistical analysis indicated no significant change from baseline, indicating no Mine-related effect except for total aluminum in benthic tissues which is consistent with elevated aluminum in surface waters.

Benthic invertebrate community metrics and tissue metals (mercury and selenium) was assessed against the aquatic invertebrate Response Framework (Figure 2). The "none" NPM for benthic invertebrate community metrics was met at all monitored impact sites in Davidson Creek (DC 05 and DC 15) and Creek 661 (661 05 and 661 10). The "none" NPM was met for selenium at all sites and for mercury at DC-15 and both Creek 661 sites (661-05 and 661-10). The "low" action level for mercury was met at DC-05 however the lack of statistically significant change from baseline and the absence of increasing trends at both Davidson Creek sites indicate that observed mercury concentrations are not at levels of concern.

FISH COMMUNITY INVENTORY AND FISH TISSUE METALS

Assessment endpoints:

- *Catch-Per-Unit-Effort (CPUE; the number of fish caught for a given amount of effort)*
- *Fish abundance (number of fish) and density (number of fish in an area)*
- *Fish health (length, age, condition)*
- *Fish tissue metals.*

Fish community data at control sites and Davidson Creek (DC-05 and DC-15) and Creek 661 (661-05 and 661-10) impact sites was summarized by CPUE, abundance and density estimates, and population structure (length frequency distributions). The 2025 fish community inventory results and analysis (comparison of control and impact and comparison to baseline) indicated there were no Mine-related effects.

The 2025 fish tissue metal concentrations were similar to or lower when compared to baseline, with no Mine-related effects detected in streams or lakes. Mercury guideline exceedances occurred at both impact and control sites, consistent with baseline patterns, while selenium remained below guidelines for all fish and sites sampled. Fish tissue metals (mercury and selenium) were assessed against the fish tissue metals Response Framework (Figure 2). Although mercury concentrations were greater than the guidelines in 2025, there was no increase from baseline tissue concentrations. Therefore, no change to mitigations is required because mitigation measures are performing as expected (i.e., the "low" action level has not been exceeded).

KOKANEE SPAWNING SURVEY

Assessment endpoints:

- *Number and density of spawning kokanee*
- *Number and density of kokanee redds (shallow depression in streambed where fish lay eggs)*
- *Fish length at 100% maturity*
- *Substrate composition*
- *Mesohabitat (smaller area within the aquatic habitat that specifically supports fish) relative abundance*

Kokanee presence and spawning activity in 2025 at all monitored sites indicate continued support of natural kokanee life history patterns. Differences in peak spawner and redd densities appear to reflect natural variability, annual hydrology, and survey timing effects. The limited number of years of available data for individual Kokanee run cohorts prevents assessment of potential Mine-related effects at this time. Spawning habitat attributes (substrate, mesohabitat) were also surveyed in 2025; this was the first-year substrate composition was collected in surveyed areas and therefore no assessment of Mine-related effects was completed.

KOKANEE FRY SPRING OUTMIGRATION SURVEY

Assessment endpoints:

- *Calculated total fry abundance for the outmigration period*
- *Length, weight, condition*

Kokanee fry outmigration abundance estimates, derived from both mark-recapture trapping efficiency and area-based methods, were substantially higher in 2025 compared to 2024 and 2023 estimates at all sites. These increases may be related to the increased sampling frequency in 2025. Kokanee fry condition was within the natural variability at both impact and control sites. Egg-to-fry survival estimates for 2025 were calculated for Davidson Creek only. The limited number of years of available data prevents assessment of potential Mine-related effects at this time.

RAINBOW TROUT SPAWNING SURVEY

Assessment endpoints:

- *Abundance of spawning rainbow trout*
- *Population structure (length and age)*
- *Length, weight, condition.*

Given the inconsistency in the timing and duration of the rainbow trout spawning surveys from 2011 to 2025, the ability to compare data across years is limited. The total abundance of rainbow trout spawners in Davidson Creek was similar in 2024 and 2025; this is likely a result of the adjustment in timing and duration of surveys to encompass the entire duration of the spawning migration made in these years. Monitored sites supported multiple cohorts of spawning adults in 2025, but the relative abundance of larger, older fish differed among sites. Condition factors did not vary among sites indicating no Mine-related effects on the condition of rainbow trout spawners. However, given the adjustments in timing and duration of spawner surveys, some of these observed differences may also reflect variation in sampling timing or detectability among years.

RECOMMENDATIONS

The 2025 AEMP monitoring represented the first year of operations and the third complete year of aquatic effects monitoring to detect Mine-related effects associated with construction and operational activities. Recommendations were identified to improve the study design to detect effects (e.g., move sampling locations to avoid confounding effects of a beaver dam) and are summarised in Table 1. No changes to the surface water quality, chronic toxicity testing, sediment quality, aquatic primary producer community, and benthic invertebrate community and tissue monitoring components were recommended. However, changes to the statistical evaluation will be considered given there will be three years of post-baseline monitoring following the completion of the 2026 AEMP monitoring program. General linear models will be examined as a potential replacement of the BACI (ANOVA) analysis given their flexibility in handling non-linear relationships and interactions. It was identified that telemetry is not required at all hydrometric monitoring

stations except for DC-05 therefore, the reference to telemetry loggers will be removed for all stream stations except for DC-05. The hydrometric program is not specific requirement of the AEMP, except to inform the analysis of effects. However, the hydrometric program does have permit conditions that must be met on an annual basis. Therefore, a separate hydrometric monitoring program (outside of the AEMP Plan as a separate standalone plan) will be considered.

The recommendations will be incorporated into the next iteration of the AEMP Plan for implementation in 2026.

TABLE 1 RECOMMENDATIONS FOR THE AQUATIC EFFECTS MONITORING PROGRAM PLAN

Sampling Component	Recommendation
Surface Water Quality	No additional sampling or analyses
Chronic Toxicity Testing	No additional sampling or analyses.
Sediment Quality	No additional sampling or analyses
Aquatic Primary Producers	No additional sampling or analyses.
Aquatic Invertebrates	No additional sampling or analyses.
Fish Community Inventory and Tissue Metal Sampling	No additional sampling or analyses except for: • Investigate potential locations for alternative regional control sites to replace the existing control sites TC-01 and 661-01, as both sites have failed repeatedly to produce fish captures that meet minimum sample size requirements for analyses. Augmenting the number of regional control sites, with comparable channel morphology and fish community composition, will improve the reliability of future analyses and strengthen the defensibility of effects assessments. Only Fish Community Inventory sampling would be conducted at alternative regional control sites, no additional tissue sampling for the analysis of metal is recommended. • Include large gee-style cylinder traps as an additional capture method at site TC-05 during tissue sampling for the analysis of metals to better target rainbow trout. The life stages observed at this site—primarily larger juveniles and adults—are less likely to enter standard minnow traps, which can introduce size-selectivity and reduce capture success. Using both the smaller minnow traps and the larger cylinder traps may increase the likelihood of capturing the full range of rainbow trout present and improve catch rates needed to meet sample size requirements.

Sampling Component	Recommendation
Kokanee Summer Spawning Survey	No additional sampling or analyses except for: • Incorporation of an additional impact survey section (CC-05A2-KO) in Middle Chedakuz Creek. In August 2025, a one-time survey during peak spawning was conducted over the entire length of Middle Chedakuz Creek to fill knowledge gaps with respect to kokanee spawning habitat use and condition; results of that survey were reported under separate cover. Based on the recommendations within that report, the addition of CC-05A2-KO will help to improve statistical robustness and spatial representativeness of the kokanee spawner program. • Alternative approaches to monitoring kokanee spawning habitat should be explored. In particular, incorporating detailed habitat surveys that quantify the extent and condition of high-use spawning areas would provide more reliable information for detecting habitat change. The current FHAP methodology, used to determine relative abundance of mesohabitat, is strongly influenced by observer interpretation and short-term environmental variability (e.g., flow, turbidity) resulting in low repeatability and inconsistent data across years. These limitations reduce the method's ability to detect subtle or cumulative habitat changes associated with Mine effects, making it poorly suited for robust effects assessments.
Kokanee Fry Spring Outmigration Survey	No additional sampling or analyses except for: • Adjust the AEMP Implementation Framework commencement trigger by reducing the ATU threshold. Monitoring in 2025 indicates that Kokanee fry outmigration in Davidson Creek and Middle Chedakuz Creek occurs at a lower ATU value than the current trigger reflects. Lowering this threshold will support more accurate, watercourse-specific timing for sampling events. • Update the egg-to-fry survival calculation to the method outlined in this report. Because this approach incorporates fish length as a variable, it likely provides a more accurate and representative estimate of egg production than relying solely on literature cited values.
Rainbow Trout Spring Spawning Survey	No additional sampling or analyses except for: • Revise data analysis of Fulton's condition of adult rainbow trout spawners to standardize on a single reproductive state (i.e., gravid or pre-spawn condition). Restricting analyses to pre-spawn fish would minimize variability in Fulton's condition associated with post-spawning weight depletion.

1. INTRODUCTION

BW Gold Ltd. (BW Gold), a wholly owned subsidiary of Artemis Gold Inc., is operating the Blackwater Mine (the Mine), an open pit gold and silver project in central British Columbia located approximately 112 km southwest of Vanderhoof (Figure 1-1). The Mine is accessed via the Kluskus and Kluskus-Ootsa Forest Service Roads and received its federal and provincial environmental approvals in 2019 under New Gold Inc., before Artemis acquired the project and transferred the Environmental Assessment Certificate to BW Gold in 2020. Since then, BW Gold has secured key authorizations including *Mines Act* Permit M-246 (2021) and *Environmental Management Act* permits for effluent and air discharges (Permits 110602[2021], 110650 [2023], and 110652 [2023]), with amendments issued in 2023 for the Mine Plan and Reclamation Program. Construction began in October 2022. The first gold and silver pour at the Mine was achieved in January 2025. Commercial production was declared in May 2025.

The EAC #M19-01 Condition 30 required the development of an Aquatic Effects Monitoring Program that *"must be implemented to the satisfaction of a Qualified Professional throughout Construction, Operations, Closure and Post-Closure and to the satisfaction of the EAO"*.

1.1 MINE WATER MANAGEMENT

The TSF stores tailings, and potentially acid generating waste rock from the development of the open pit and ore processing (Figure 1-2). The TSF also includes a storage allowance for two supernatant ponds within each of the adjacent sites (TSF C and TSF D). The recoverable seepage from TSF C and TSF D (when constructed) ponds, and runoff from the Main Dam D will be collected into the Interim Environmental Control Dam (IECD) or the future ECD and recycled back to the TSF (Figure 1-2). Surplus water from TSF C will be treated at a membrane water treatment plant (WTP) for nitrogen, sulphate, and metals prior to pumping to the water management pond (WMP). Seepage from the TSF C pond not collected into the ECD has the potential to contribute to groundwater that enters Davidson Creek and Creek 661 (Figure 1-2). Davidson Creek will also receive TSF D pond (when constructed) seepage to groundwater (Figure 1-2).

Surplus non-acid generating waste rock and overburden from the Open Pit, and not used in construction, will be placed in the Lower and Upper waste stockpiles. Runoff and seepage from the waste stockpiles will be collected at the base of the stockpiles and directed to a collection pond and treated prior to pumping to the WMP (Figure 1-2).

During operations, runoff and infiltration from the low-grade ore stockpile will be collected and neutralized with lime (in the processing plant) to increase the pH, and precipitate metals before gravity conveyance to the TSF (Figure 1-2). The Open Pit sump water (surface water that collects in the pit sump, and groundwater from dewatering and depressurization wells) will be treated for metals, and water will be pumped for use in the mill or treated water sent to the WMP (Figure 1-2).

The WMP is used to manage water released from the WTPs as well as non-contact surface runoff diverted from catchment area upslope of TSF C (Figure 1-2). The WMP provides make-up water to support ore processing at the mill, and water not required for mill operations will be pumped to the freshwater reservoir (FWR) once constructed.

The primary purpose of the FWR (located immediately downstream of the IECD) is to maintain environmental flows in Davidson Creek through a controlled release of water. The FWR (when constructed) will receive: 1) water pumped from the WMP, which consists of both treated contact water and diverted non-contact water; 2) diverted non-contact water via the Central and Northern Diversion channels; and 3) water from Tatelkuz Lake via the Freshwater Supply System later in Operations (Figure 1-2). Thus, the FWR pond outlet is considered a final discharge location (point of compliance) for the Mine at which permit limits, and Metal and Diamond Mining Effluent Regulation (MDMER) will apply.

There are three sediment control ponds (SCPs) permitted for discharge:

1. TSF Stage 1 SCP (Construction phase only) - Captured background surface runoff, groundwater, and runoff from the Davidson Creek basin and Mine Area Creek basin. Discharged to Davidson Creek during Construction and is no longer operational.
2. Plant Site SCP (Construction and Operations) - Captures contact water around the Plant Site and is permitted to discharge effluent to ground via rapid infiltration basins (RIBs) during the Construction phase. Water collected in the Plant Site SCP during Operations phase will either be used for mining operations or will be transferred to the TSF.
3. Downstream Aggregate Borrow Area SCP (to be constructed in Operations). Discharge from the Downstream Aggregate Borrow Area SCP (when constructed) will be directed to Davidson Creek.

The permanent operations camp stormwater runoff is authorized under the *Environmental Management Act* (EMA) Permit PE-110652 as a non-point source discharge to ground.

Creek 705 will receive diverted flows from the headwaters of Lake 1682, resulting in a predicted increase in flow of 10 L/s on an average annual basis at all locations on Creek 705. Creek 705 will not receive mine contact water as surface water or as seepage to groundwater, and no changes in water quality were predicted for Creek 705 (BW Gold 2022).

1.2 REGULATORY FRAMEWORK

BW Gold received EMA Permit PE-110602 on June 24, 2021, authorizing early construction works for the Mine. These works include clearing, grubbing ditching, and site levelling at the Plant Site location and sediment and erosion controls, including construction of ditches, diversions, and a SCP. The Construction phase of the Mine was initiated in late September 2022 (Early Works Permit M-246).

BW Gold received an amended *Mines Act* Permit M-246 on March 8, 2023, approving the Mine Plan and Reclamation Program and superseding the previous version. BW Gold received EMA Permit PE-110652 on May 3, 2023, authorizing discharge of effluent to surface water and groundwater from the Blackwater Mine site. BW Gold received a *Fisheries Act* Authorization in June 2023 to offset losses to fish habitat that result from the deposition of a deleterious substance into water

bodies beneath the tailings storage facilities C and D (excluding dam footprints), the ore stockpiles, and the upper overburden stockpile.

The AEMP Plan (Version 4.0) was developed to meet the content requirements of Permit PE-110652 Condition 4.6.3 (the concordance is provided in Table 1.2-1) and EAC #M19-01 Conditions 28 and 30 (the concordance is provided in Table 1.2-2; ERM 2025b).

This AEMP interpretive report meets the PE-110652 Condition 4.6.5: *An AEMP interpretive report including interpretation of data and recommendations, including all acute and chronic test toxicity results, must be prepared by a Qualified Professional, and the permittee must submit the interpretive report to the director as part of the Annual Report for the year in which the AEMP was required to be conducted.*

Comments by Nechako First Nations (NFN), on the 2024 AEMP Interpretive Report were received by BW Gold in May 2025 (LGL Limited on behalf of NFN) and June 2025 (Source Environmental Associates Inc. [Source] on behalf of NFN). Where applicable, the comments have been addressed in this report:

- Differentiating between wildfire and mine related impacts (Source Comment ID#1] is addressed in Section 1.6.
- Rationale for missed stream field data (Source Comment ID#2] is addressed in Section 2.3.
- Guidelines and benchmarks are displayed on figures (Source Comment ID#4] provided in Appendix A-7 and A-8 and in Section 2.3-1.
- Zinc concentrations in Creek 661 (Source Comment ID#5, #6] potentially related to the Q1 2025 dust event from the ore stockpile are discussed in Section 2.3 (surface water), Section 4.3 (sediment quality), and Section 6.3 (Benthic Invertebrate Community and Tissue Metals).
- Multiple comments with respect to resident fish community metrics (NFN Comment ID#3, #4, #5, #6), as well as salvaged fish (NFN Comment ID#2) are addressed in Section 7.3.1.
- Mesohabitat data presented in tabular format (NFN Comment#7) are provided in Section 8.3.5.
- Multiple comments with respect to rainbow trout spring spawner surveys, including CPUE, abundance (NFN Comment ID#10, #11) and box traps (NFN Comment ID#14) are addressed in Section 10.3.

TABLE 1.2-1 CONCORDANCE OF THE ENVIRONMENTAL MANAGEMENT ACT PERMIT 110652 AQUATIC EFFECTS MONITORING PROGRAM

***Environmental Management Act* Permit 110652 Condition**	**Section in the Aquatic Effects Monitoring Program Plan, Version 4.0**
4.6 Aquatic Effects Monitoring Program	
4.6.1 The permittee must cause a Qualified Professional to develop an Aquatic Effects Monitoring Program (AEMP) and the permittee must submit an AEMP Plan for approval to the director within 60 days after the issuance of this authorization.	Section 7; the authorization was issued on May 2, 2023, therefore the AEMP Plan, Version 1.0 was submitted by July 2, 2023

***Environmental Management Act* Permit 110652 Condition**	**Section in the Aquatic Effects Monitoring Program Plan, Version 4.0**
4.6.2 The permittee must engage with the UFN, LDN and CSFNs during the development of the draft AEMP Plan. The permittee must provide a summary of the engagement, including comments received and permittee responses with an explanation of efforts made to resolve comments, in a cover letter as part of the AEMP Plan submitted for approval.	Section 2.1 and Appendix A
4.6.3 The AEMP Plan must include, but is not necessarily limited to, the following:	
• A conceptual model that describes the relationships between mining-related activities and potential effects on the aquatic environment,	Section 3.2
• The objectives and a list of questions the AEMP is intended to answer,	Section 1.1 (objectives); Section 4 (list of questions)
• A detailed description of the design of the monitoring program, including a list of assessment endpoints and measurement endpoints that will be incorporated into the AEMP,	Section 4 (design); assessment and measurement endpoints provided in: • Section 4.3.1 (hydrology) • Section 4.4.1.1 (surface water temperature) • Section 4.4.2.1 (surface water quality) • Section 4.4.3.1 (chronic toxicity testing) • Section 4.5.1 (sediment quality) • Section 4.6.1 (periphyton) • Section 4.7.1 (benthic invertebrates) • Section 4.8.1.1 (fish community inventory and tissue metals) • Section 4.8.2.1 (kokanee summer spawning) • Section 4.8.3.1 (kokanee fry spring outmigration) • Section 4.8.4.1 (rainbow trout spring spawning)
• Trigger response framework for nutrient concentrations and periphyton biomass	Section 5.2.3 (periphyton biomass and nutrient concentrations)
• The monitoring stations and sampling components outlined in Appendix C	Table 4.2-1 and Table 4.2-2
• The means by which the data collected will be analyzed to determine the effects on the aquatic environment.	Section 4.3.4 (hydrology) Section 4.4.1.4 (surface water temperature) Section 4.4.2.3 (surface water quality) Section 4.4.3.2 (chronic toxicity testing) Section 4.5.2.3 (sediment quality) Section 4.6.3 (periphyton) Section 4.7.3 (benthic invertebrates)

***Environmental Management Act* Permit 110652 Condition**	**Section in the Aquatic Effects Monitoring Program Plan, Version 4.0**
	Section 4.8.1.3 (fish community inventory and tissue metals) Section 4.8.2.3 (kokanee summer spawning) Section 4.8.3.3 (kokanee fry spring outmigration) Section 4.8.4.3 (rainbow trout spring spawning)
4.6.6 The permittee must cause a Qualified Professional to review and update the AEMP Plan based on the recommendations included in the AEMP interpretive report. The updated AEMP Plan must be submitted to the director for approval within 30 days of submission of AEMP interpretive report. The permittee must provide justification where any of the recommended modifications have not been included in the updated AEMP Plan in a cover letter for the updated AEMP Plan.	Section 7; the AEMP Interpretive Report was issued on March 31, 2025, therefore the AEMP Plan, Version 4.0 was submitted by April 30, 2025.

LDN = Lhoosk'uz Dené Nation; UFN = Ulkatcho First Nation; CSFN = Carrier Sekani First Nations, now Nechako First Nations

TABLE 1.2-2 CONCORDANCE OF EAC #M19-01 CONDITIONS WITH THE AQUATIC EFFECTS MONITORING PROGRAM PLAN

Environmental Assessment Certificate	**Section in the Aquatic Effects Monitoring Program Plan, Version 4.0**
Condition 28: Chedakuz Creek and Tatelkuz Lake Water Quality Monitoring Plan	
The plan must include at least the following:	
a) Monitoring locations;	Section 4.2
b) Frequency of monitoring;	Section 4.2
c) The means by which the baseline information in Condition 27, Water Quality Report, and any other appropriate information or criteria as determined by a Qualified Professional, will be used to determine if there are adverse effects due to the Project to: i. Tatelkuz Lake; and ii. Chedakuz Creek upstream of Nechako Reservoir;	Sections 4.4.2
d) How the Holder has considered YDWL, other Aboriginal policies made available to the Holder from Aboriginal Groups, and ENV guidance in development of the criteria in paragraph c);	Section 4.4.2 (BW Gold has been collaborating with the NFNs in regard to implementation of the YDWL and discussions with the NFNs are ongoing.)
e) Conditions, if any, under which monitoring would no longer be required; and	Section 4

Environmental Assessment Certificate	Section in the Aquatic Effects Monitoring Program Plan, Version 4.0
f) The means by which the Holder will communicate this information to Aboriginal Groups, including identification of the type of information to be provided, the frequency of reporting and the implications of the water quality observed at Chedakuz Creek for the Nechako Reservoir. Reports must include a summary written for a lay audience.	Section 6
Condition 30: Aquatic Effects Monitoring Plan	
The Holder must retain a Qualified Professional to develop an Aquatic Effects Monitoring Plan (AEMP).	Section 1.2 and 7
The AEMP must be developed in consultation with EMPR, ENV, FLNRORD, and Aboriginal Groups.	Section 2; Ongoing
The AEMP must include at least the following:	
a) a description of how the plan takes into consideration the YDWL and any other Aboriginal water policies made available to the Holder by the Aboriginal Groups;	Section 1.3, Section 4.4.2 (BW Gold has been collaborating with the Nechako First Nations in regard to implementation of the YDWL and discussions are ongoing.)
b) a description of the Project, associated activities, and study area;	Section 1, Section 4.1
c) a conceptual model that describes the relationships between mining-related activities and potential effects on the aquatic environment;	Section 3.2
d) a description of the water quality issues and concerns with respect to the Project that exist in the vicinity of the Project Site;	Section 3
e) the objectives and a list of questions the AEMP is intended to answer;	Section 1.1 (objectives); Section 4 (list of questions)
f) a detailed description of the design of the monitoring program, including a list of assessment endpoints (for example, survival, growth, and reproduction of fish in receiving waters) and measurement endpoints (for example, surface water chemistry) that will be incorporated into the AEMP;	Section 4 (Tables 4.3-1, 4.4-1, 4.4-2, 4.4-4, 4.5-1, 4.5-3, 4.6-1, 4.7-1, 4.8-1, 4.8-2, 4.8-4, 4.8-5, and 4.9-1)
g) a description of the locations, timing, and frequency of sampling for each of the measurement endpoints and metrics (e.g., concentrations of major ions in surface water) that will be included in the AEMP, including those for surface water chemistry, surface water toxicity, sediment chemistry, sediment toxicity, tissue chemistry, aquatic plant communities, aquatic invertebrate communities, fish communities, and aquatic-dependent wildlife communities;	Section 4.2 (Table 4.2-2 and 4.2-3); see Section 4.6.1 for why aquatic plant communities are excluded

Environmental Assessment Certificate	Section in the Aquatic Effects Monitoring Program Plan, Version 4.0
h) the means by which the data collected under the AEMP will be analyzed to determine the effects of the Project on the aquatic environment;	Section 4.3.4 (hydrology) Section 4.4.1.4 (surface water temperature) Section 4.4.2.3 (surface water quality) Section 4.4.3.3 2 (chronic toxicity testing) Section 4.5.2.3 (sediment quality) Section 4.6.3 (periphyton) Section 4.7.3 (benthic invertebrates) Section 4.8.1.3 (fish community inventory and tissue metals) Section 4.8.2.3 (Kokanee summer spawning) Section 4.8.3.3 (Kokanee fry spring outmigration) Section 4.8.4.3 (Rainbow Trout spring spawning)
i) means by which the AEMP will inform the Country Foods Monitoring Plan (Condition 41);	Section 1.5
j) a list of reports that will be prepared to disseminate the results of the AEMP, including a description of the proposed frequency, timing, structure, and content of each report. The reports must include a report that summarizes the results of the AEMP in language understandable to a lay audience; and	Section 6.1 (Annual AEMP Interpretive Report), Section 6.2 (Decision Statement Annual Reporting), Section 6.3 (EAC Reporting), Section 6.4 (Plain Language Report)
k) the process and timing for sharing monitoring and study results, including the reports required under paragraph (j), with ENV, EMPR, FLNRORD, Aboriginal Groups and the EMC.	Section 6
The adaptive management aspect of this plan, as required under Condition 3, may be in a stand-alone section of this plan.	Section 5
The Holder must provide the draft plan that was developed in consultation with EMPR, ENV, FLNRORD, and Aboriginal Groups to EAO, EMPR, ENV, FLNRORD, and Aboriginal Groups for review a minimum of 60 days prior to the planned commencement of Construction or as listed in the Document Submission Plan required by Condition 10 of this Certificate.	Section 2
The AEMP, and any amendments thereto, must be implemented to the satisfaction of a Qualified Professional throughout Construction, Operations, Closure and Post-Closure and to the satisfaction of the EAO.	Ongoing, Section 1.2 and 6
Condition 2: Plan Development	
Where a condition of this Certificate requires the Holder to develop a plan, program or other document, any such plan, program or other document must, at a minimum, include the following information:	

Environmental Assessment Certificate	Section in the Aquatic Effects Monitoring Program Plan, Version 4.0
a) purpose and objectives of the plan, program or other document;	Section 1.1
b) roles and responsibilities of the Holder and Employees;	Section 1.2
c) names and, if applicable, professional certifications and professional stamps/seals, of those responsible for the preparation of the plan, program, or other document;	Section 7
d) schedule for implementing the plan, program or other document throughout the relevant Project phases;	Section 4
e) means by which the effectiveness of the mitigation measures will be evaluated including the schedule for evaluating effectiveness;	Section 5
f) schedules and methods for the submission of reporting to specific agencies, Aboriginal Groups and the public and the required form and content of those reports; and	Section 6
g) process and timing for updating and revising the plan, program or other document, including any consultation with agencies and Aboriginal Groups that would occur in connection with such updates and revisions.	Section 2 (Engagement) and Section 6.5 (Plan Revisions)
Condition 3: Adaptive Management	
Where a condition of this Certificate requires the Holder to develop a plan, program or other document that includes monitoring, including monitoring of mitigation measures or monitoring to determine the effectiveness of the mitigation measures, the Holder must include adaptive management in that plan.	Section 5
The objective of the adaptive management is to address the circumstances that will require the Holder to implement alternate or additional mitigation measures to address effects of the Project if the monitoring shows that those effects:	Section 5.2
a) are not mitigated to the extent contemplated in the Application;	
b) are not predicted in the Application; or	
c) have exceeded the triggers identified in paragraph g) of this condition.	
The adaptive management in the plan must include at least the following:	
a) the monitoring program that will be used including methods, location, frequency, timing and duration of the monitoring;	Section 4

Environmental Assessment Certificate	Section in the Aquatic Effects Monitoring Program Plan, Version 4.0
b) the baseline information that will be used, or collected where existing baseline information is insufficient, to support the monitoring program;	Section 3 and 5.2
c) the scope, content and frequency of reporting of the monitoring results;	Section 6
d) the identification of qualitative and quantitative triggers, which, when observed through monitoring required under paragraph d), will require the Holder to alter existing, or develop new, mitigation measures to avoid, reduce, and/or remediate effects;	Section 5.2 (Tables 5.2-2, 5.2-3, 5.2-4, 5.2-5, 5.2-6, and 5.2-7)
e) the methods that will be applied to detect when a numeric trigger, or type or level of change referred to in paragraph g), has occurred;	Section 4 (Data Analysis sections) and Section 5.2
f) a description of the process for and timing to alter existing mitigation measures or develop new mitigation measures to reduce or avoid effects;	Section 4 (Data Analysis sections) and Section 5.2
g) identification of the new and/or altered mitigation measures that will be applied when any of the changes identified in paragraphs a) to c) occur, or the process by which those will be established and updated over the relevant timeframe for the specific condition;	Section 4 (Data Analysis sections) and Section 5.2
h) the monitoring program that will be used to determine if the altered or new mitigation measures and/or remediation activities are effectively mitigating or remediating the effects and or avoiding potential effects; and	Section 4 (Data Analysis sections) and Section 5.2
i) the scope, content and frequency of reporting on the implementation of altered or new mitigation measures.	Section 6
If there are any requirements or mitigation measures required in the plan, program or other document for which adaptive management, or elements of adaptive management listed in paragraphs d) to l) are assessed to be not appropriate or applicable, the plan must include identification of those requirements and measures, and the rationale for that assessment.	Ongoing

1.3 PURPOSE AND OBJECTIVES

The purpose of the AEMP is to provide information on the aquatic receiving environment necessary to achieve the following objectives for the period of Construction and Operations to date (October 2023 to December 2025):

- Detect the Mine-related effects on the aquatic ecosystem components (including water quality).
- Confirm water quality predictions as presented in Lorax (2022a), and effects assessments as presented in the *Joint Application for Mines Act* and *Environmental Management Act* Permits Application (Chapter 6 of BW Gold 2022).
- Meet permit and regulatory requirements for effluent and receiving environment water quality.
- Assess the performance of mitigation and management measures.
- Provide the necessary feedback and information for the adaptive management of potential effects related to the Mine.

The AEMP has been designed to assess the potential long-term effects (i.e., changes from year to year) in each of the physical and chemical components identified in Section 1.5.1. For each of the AEMP components, sampling and data analysis have been completed to address the following questions:

- Are AEMP component assessment endpoints at impact sites changing from baseline conditions or reference ranges (e.g., concentrations higher than the site-specific baseline data or reference ranges) as a result of the Mine?
- Are AEMP component assessment endpoints changing in ways that were not predicted by models or is mitigation less successful than anticipated (e.g., concentrations of parameters in water higher than predicted by the surface water quality model)?
- Are AEMP component assessment endpoints at impact sites changing to levels that may be associated with effects as a result of the Mine (e.g., does the change result in an exceedance of a WQG or another benchmark)?

These questions also directly feed into the adaptive management framework to define numeric performance metrics for various action levels.

1.4 LINKAGES TO OTHER MONITORING PROGRAMS

Other management and monitoring plans have linkages to the AEMP to provide inputs or information to aid in the interpretation of data and provide outputs for use in other monitoring programs. Monitoring surface water and groundwater flow and quality within the mine site (i.e., WMP or WTP effluent) or effluent at the end of pipe are not included in the AEMP. The Mine Site Water and Discharge Monitoring and Management Plan (MSDP) provides the framework for monitoring surface water, groundwater, and effluent quality and quantity within the mine site. Results from the MSDP are used to inform the interpretation of AEMP monitoring results. For example, the MSDP includes monitoring of effluent quality at discharge points, which can be useful in understanding changes or trends in water quality measured in downstream aquatic receiving environments. Similarly, groundwater monitoring can serve to confirm seepage

pathways and seepage quality, which can also inform the interpretation of water quality monitoring results in the aquatic receiving environment downgradient of the Mine site.

Results of the AEMP will inform the Country Foods Monitoring Program (CFMP), which is required by EAC #M19-01 Condition 41. Specifically, the AEMP surface water quality and fish tissue metal monitoring was used in the CFMP to fulfil the requirements for water quality sampling (EAC #M1901 Condition 41(d)(vii)) and fish tissue sampling (EAC #M19-01 Condition 41(d)(vi)). As required by EAC #M19-01 Condition 41(d)(vi)(i), fish tissue and surface water quality samples were co-collected at the same site and time, as described in the Field Methods under Section 2 (Surface Water Quality) and Section 7 (Fish Community Inventory and Tissue Metal Sampling).

The Wildlife Mitigation and Monitoring Plan (WMMP) describes a range of monitoring programs for wildlife, including water-dependent wildlife. The WMMP includes programs for monitoring habitat loss, toad mortality on roads, toad breeding ponds, and monitoring the Mine facility waterbodies. The WMMP includes surveys to monitor potential impacts of the Mine on waterbird populations, focusing on areas closest to the mine site where habitat alteration may occur (and compared to control sites located further away). Additional targeted assessment of amphibians or waterbirds as a scheduled AEMP monitoring component will only be completed if triggered through the adaptive management response framework to aid in the understanding the effects of guideline exceedances and/or significant Mine-related changes in water quality.

1.5 2025 MINE ACTIVITIES

1.5.1 OPERATIONS AND CONSTRUCTION

Year 1 of Operations at the Mine began in 2025 and included continued development of the Open Pit using conventional drill, blast, load and haul techniques, and operations of the mill. Several significant milestones were achieved in Q1 2025 including the commencement of mill operations (January 22), initial deposition of tailings (January 25), and placement of Low-Grade Ore (LGO) on the LGO Stockpile (March 14). By May 2025 commercial production was achieved, and operations continued through the year.

Construction activities continued in 2025 with a focus on the following:

- Continued development of TSF Dam C
- Development of the LGO stockpile foundation panels
- Construction of water management infrastructure
- Establishing ancillary buildings and associated facilities

Tree clearing and soil salvage occurred where needed to support those activities. No works occurred on the Mine Access Road, Upper or Lower Waste Rock Stockpiles, Fresh Water Supply System (FWSS) (excluding the FWR), or Northern Diversion System.

During the construction of the FWR extensive tree clearing in the immediate surrounding area was completed in May/June 2025. The tree clearing was completed upstream of Davidson Creek receiving environment.

1.5.2 WATER MANAGEMENT CURRENT CONDITIONS

Construction and operation of water management infrastructure occurred in 2025 to support water management at the Mine. Water management areas at the Mine are the Pit Area, TSF, Stockpile Areas, and Plant Site Area and are connected by the water treatment systems, the WMP, and FWR.

Two water treatment systems have been commissioned: the Metals WTP (2024), and the Lime Neutralization System (LNS) (January 9, 2025). Neither water system treated water in 2025, because the water sources for the metals WTP were used in the mill, and monitoring results from the LGO Stockpile Pond in 2025 did not yet indicate a pH that required treatment by the LNS.

The WMP was established in 2024 to collect runoff from the upstream drainage (Mine Area Creek), and water pumped from other collection points. In 2025, the WMP collected water from Mine Area Creek and the Central Diversion System (CDS). Water from the WMP was either conveyed to the mill or the former Davidson Creek upstream of the future FWR. In 2025 discharge of the non-contact water to the former Davidson Creek occurred intermittently as pond volume and water quality allowed. Water from the CDS was primarily conveyed directly to former Davidson Creek in 2025.

Construction of the FWR began in October 2025 with completion anticipated in 2026. Once operational, the FWR will receive water from the WMP and surface run-off from contributing catchments.

Within each of the water management areas the following has been completed:

- Pit Area—Development of the Open Pit began in 2024 and continued through 2025 as operations commenced. In 2025 water collected in the pit was directed to a sump and moved to the LGO Stockpile Pond, while water intercepted by dewatering wells was directed to the mill as make-up water.
- TSF Area—Substantial completion of the TSF C Dam and IECD occurred in 2024, supporting the initial use of these facilities. In 2025, deposition of PAG material in the TSF continued (initiated in 2024), and tailings depositions into the TSF was initiated on January 25, 2025, and continued through the year. As deposition of PAG and tailings occurred, construction of the TSF continued to support Year 1 of Operations. Seepage from the TSF was collected by the IECD and pumped back to the TSF intermittently through 2025. The CDS was established in 2024 to divert surface water from the upslope areas around the TSF to the WMP or directly to former Davidson Creek, via surface water collection channels and the Central Water Transfer Pond. This system operated through 2025.
- Stockpile Areas—In 2025 foundation panels for the LGO Stockpile were complete, including the foundation drains and the LGO Stockpile Pond. Initial deposition of LGO occurred on March 14, 2025. Water from the LGO Stockpile Pond is conveyed to the mill, where it is combined with the process water stream for neutralization via the LNS prior to discharge to the TSF. In 2025, pumping from the LGO Stockpile Pond to the mill occurred intermittently and was directed to the mill as designed. Monitoring of the LGO Stockpile Pond in 2025 did not indicate a pH that required treatment by the LNS.

- Plant Site Area—In 2025, plant site runoff was collected by perimeter ditches and directed to the PS-SCP. The PS-SCP water is intermittently pumped to the mill to be used as processing make-up water.

In December 2025 construction of the Raw Water Pond (RWP) and Process Water Pond (PWP) began. Construction is not yet complete. When operational the RWP will store treated water from the Metals WTP which will be conveyed to the mill, or overflow to the PWP unless otherwise directed, while the PWP will store untreated water sources such as the open pit or stockpiles, which will be directed to the mill, or the metals WTP for treatment.

1.5.3 DISCHARGES TO THE RECEIVING ENVIRONMENT

There were no authorized discharges of effluent to the receiving environment (PE-110652) between January 1 to December 31, 2025. Mine effluent was pumped to the mill as make-up water to support production. The diverted non-contact water sources from the WMP, CDS, and northern diversion channel (i.e., the Creek 688 watershed) were conveyed to the former Davidson Creek upstream of the FWR.

However, the following mine-related events were recorded with the potential to affect the aquatic receiving environment:

- In Q1 of 2025 an ore stockpile dust event was observed. Mapping determined that the observed dust deposited was entirely within the mine site boundary (Lorax 2025). However, there is the potential for some dust to travel and deposit beyond the visible and mapped extent of deposited dust. Non-visible dust particles were likely smaller, and the dust-bound metals potentially transported to the receiving environment by these smaller particles would be minimal. Based on prevailing winds at the Mine, Creek 661 was the most likely receiving environment to be potentially affected by the stockpile dust event.
- Between March 12 and 15, 2025 TSS laden water was released from site into Davidson Creek due to an Erosion and Sediment Control failure upstream.
- In October 2025, a review of the groundwater seepage samples collected downstream of the TSF C and the IECD indicated that the concentrations exceeded the Level 3 trigger concentrations established in the Draft Groundwater Trigger Response Plan for Non-Point Source Discharges to Ground. Level 3 triggers are defined by exceedance of the Contaminated Sites Regulation standard for aquatic life for a given parameter.

1.6 WILDFIRES

Several wildfires occurred in the vicinity of the Mine in 2025, however construction, operations and monitoring activities at the Mine were less impacted when compared to wildfire activity occurring in 2023 and 2024 (Figure 1.6-1). No evacuations occurred, no fires intercepted the mine site, Forest Service Road, transmission line, or planned offsetting sites, and the timing and completion of AEMP monitoring was not impacted. Smoke produced from the 2025 fires did impact air quality at the Mine during the summer months.

DATE: 03/11/2026

PROJECTION: NAD 1983 UTM Zone 10N
SCALE: 1:170,000 when printed at 11x17

There was extensive wildfire activity in the mine area in 2023, and 2024 (Figure 1.6-1). No additional water quality stations have been added in response to the wildfires because the purpose of the AEMP is to assess mine-related effects. In addition, Davidson Creek upstream of the Mine receiving environment has already been affected by wildfires and/or is planned to be affected by future Mine activities. However, given the potential for long-term effects of the wildfires (i.e., soil mobilization to the receiving environment as a result of the loss in vegetation) the potential effects of the 2023 and 2024 wildfires were considered in the evaluation of effects.

Potential effects of the 2023 and 2024 wildfire on water quality in streams immediately downstream of the extent include erosion of sediments and deposition of ash and debris into surface waters. Thus, greater TSS concentrations or turbidity in streams following the wildfire can be attributed to the wildfire and not Mine-related effects; however, observed magnitude and timing of the increase will also be related to burn intensity, stream flows, and precipitation events. Nutrients, sulphate, pH, total dissolved solids, chloride, and organic carbon may also increase in waters post-wildfire as a result of the deposition of ash and soil erosion (Water Research Foundation 2013; BC Health 2024). Similar to TSS and turbidity, the magnitude of the change is related to amount and intensity of precipitation events post-fire. An increase in metals in the particulate form may also be observed however the peak and magnitude depends on the mobilization to surface water and therefore may not be observed immediately after the wildfire.

Given there were no authorized mine discharges to the receiving environment in 2025, the aquatic effects analysis attempted to differentiate Mine-related effects from the effects from the 2023 and 2024 wildfires. Wildfire potential effects are discussed as follows:

- Non-contact water diversions of overland flow from the 2023 fire-impacted upper Davidson Creek watershed contributing to increases in TSS and total metals in Davidson Creek when diverted water was returned to the former Davidson Creek downstream of the IECD either directly via the CDS or from the WMP.
- Greater concentrations of TSS and total metals may be directly related to the 2023 fire-impacted upper Davidson Creek watershed. Thus, with the 2025 snowmelt beginning in late March and freshet conditions (and associated overland flow over the burned topsoil and burned organic matter), there may be greater contributions of particulate-bound metals to Davidson Creek not observed at control sites.
- The 2023 fire-impacted Creek 661 tributaries located within the Mine site may also contribute greater concentrations of TSS and particulate-bound metals not observed at control sites beginning with the 2025 snowmelt in late March and freshet conditions (and associated overland flow over the burned topsoil and burned organic matter).
- Greater concentrations of TSS and total metals beginning with the 2025 snowmelt in late March and freshet conditions may be directly related to the 2024 fire-impacted Creek 661, Tatelkuz Lake, and potentially Chedakuz Creek sites downstream of Tatelkuz Lake.

1.7 SAMPLING PROGRAM

1.7.1 STUDY AREA

The Mine is located on the Nechako Plateau in the Nechako River watershed within the Fraser River drainage. Specifically, the Blackwater deposit is located on the north slope of Mount Davidson, in the headwaters of the Davidson Creek watershed which flow to Chedakuz Creek, then on to the Nechako Reservoir.

The AEMP study area includes four stream watersheds and one lake anticipated to be potentially influenced by Mine-related activities because they are downstream of current or planned mine infrastructure or discharge points (Figure 1.7-1):

- Davidson Creek
- Creek 661
- Chedakuz Creek
- Turtle Creek
- Tatelkuz Lake

The study area also includes three stream watersheds and one lake upstream or outside of the immediate zone of influence of the Mine and are considered control sites (regional control sites):

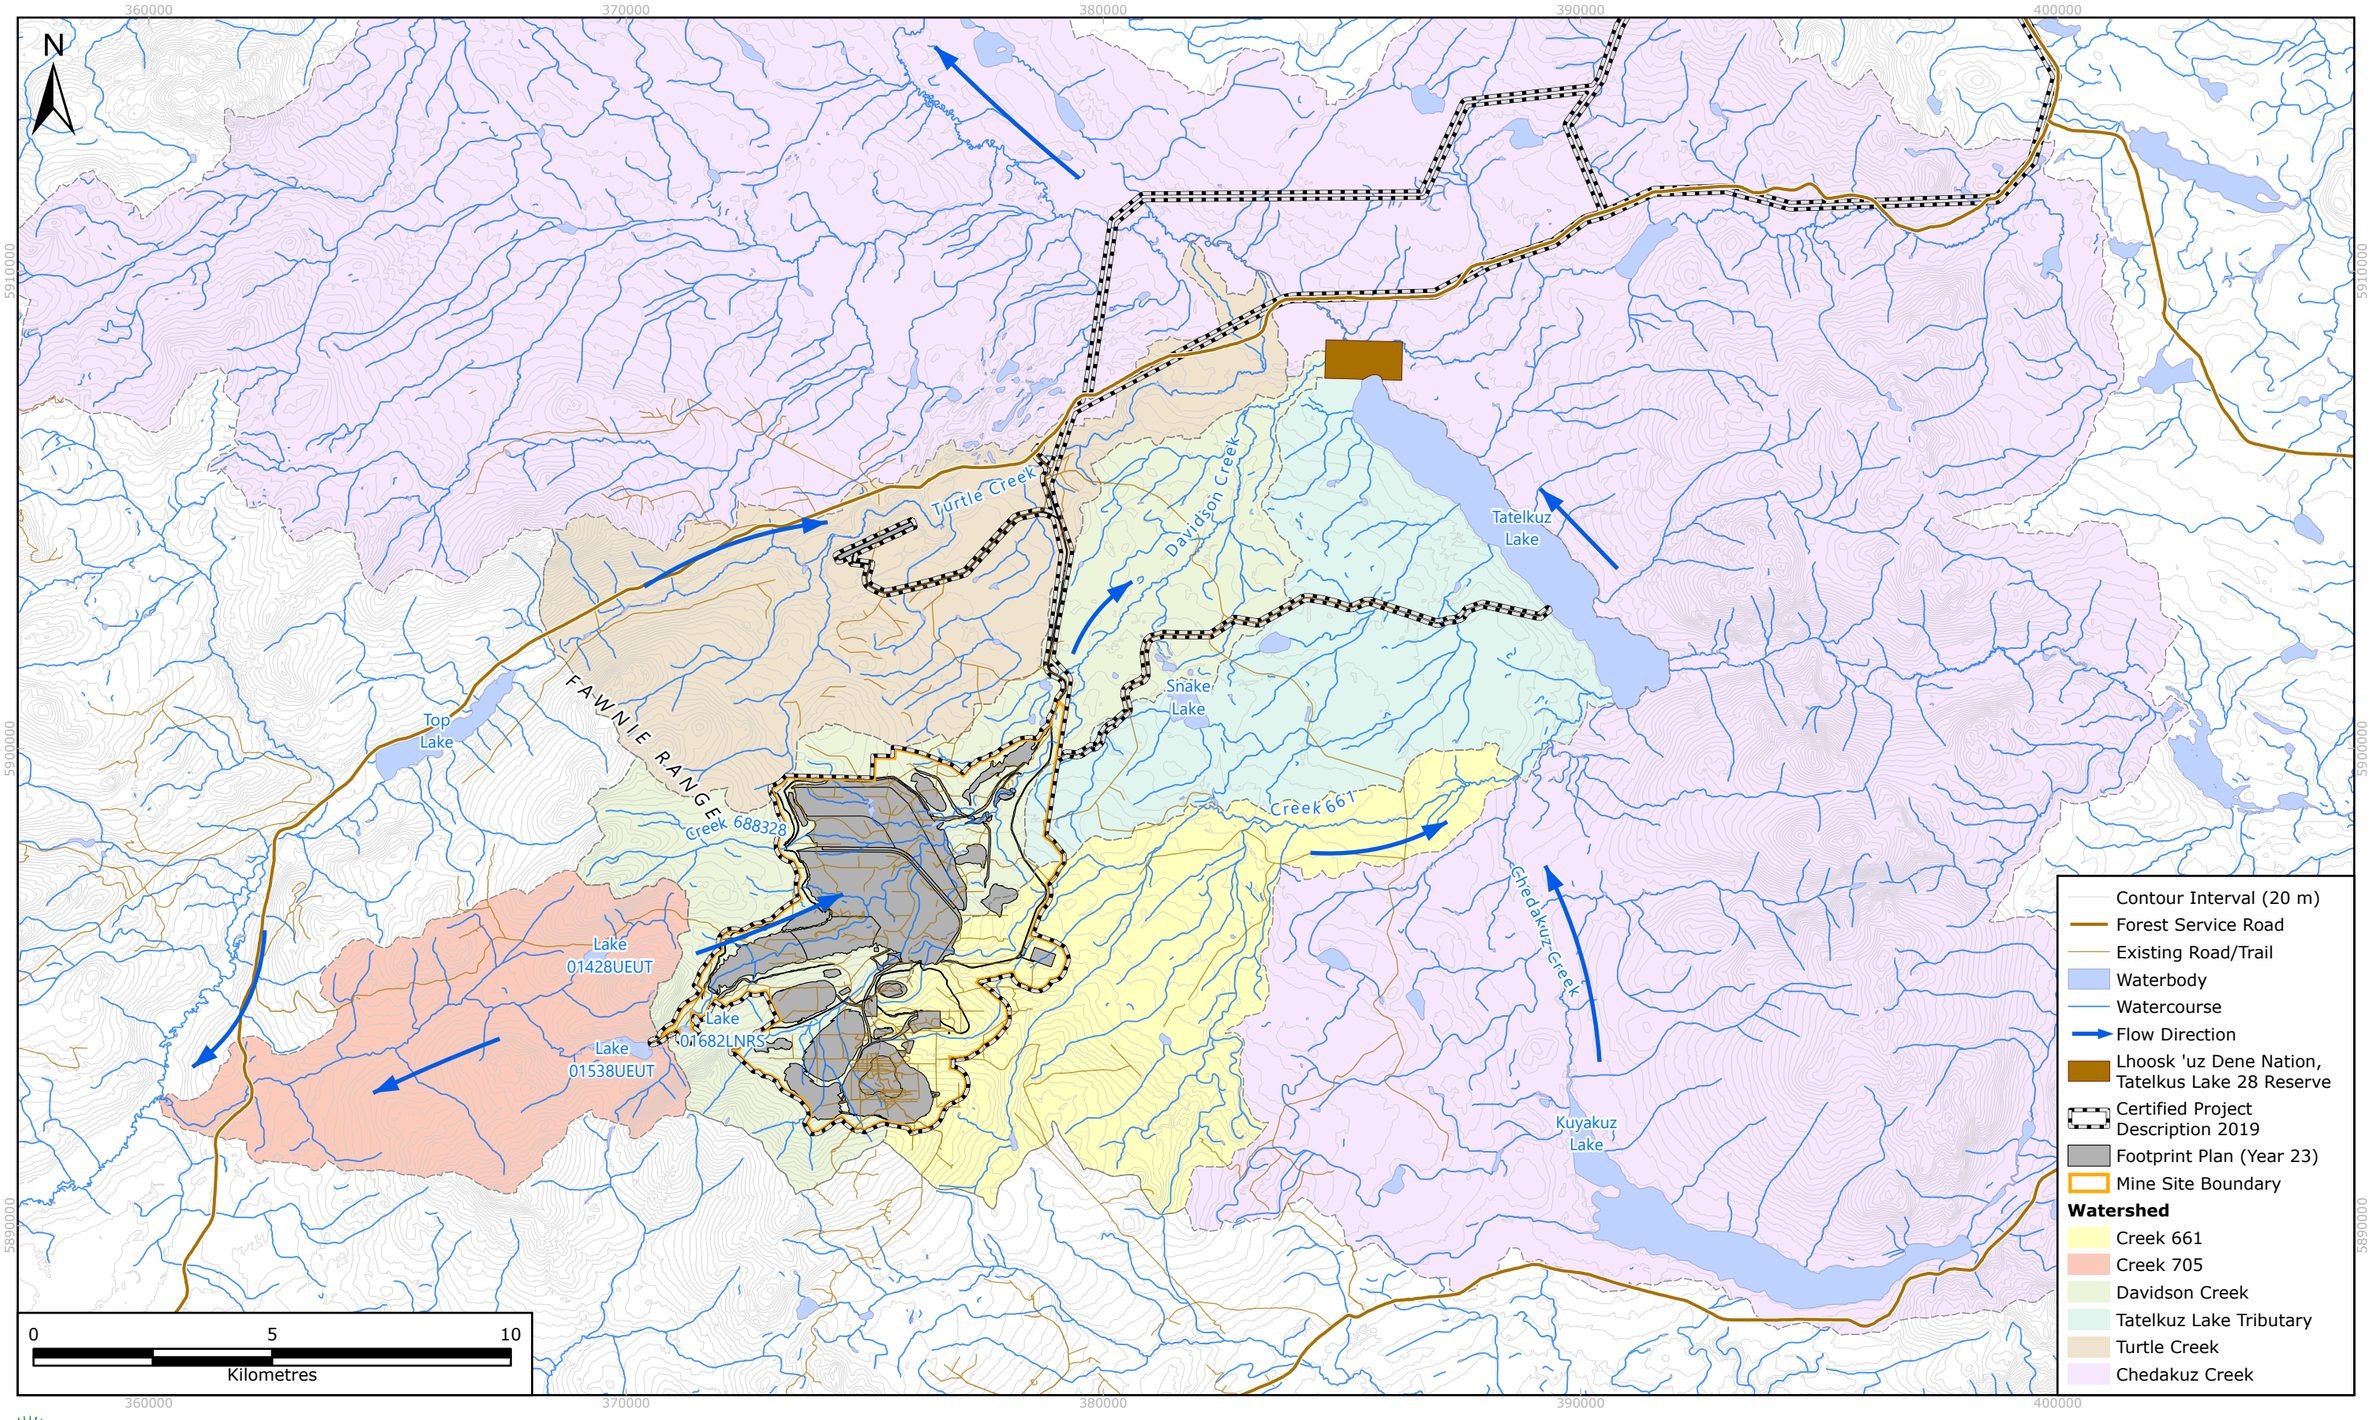
- Creek 705
- Fawnie Creek Tributary
- Mathews Creek
- Kuyakuz Lake

Davidson creek flows northwest from the Mine site toward Chedakuz Creek, with the confluence of the two creeks being approximately 800 metres (m) downstream of Tatelkuz Lake on the Lhoosk'uz Dene Nation, Tatelkus Lake 28 Reserve (Figure 1.7-1). Water discharged from the mine site via the FWR outlet will report directly to upper Davidson Creek. Unrecovered seepage from mine site infrastructure (primarily TSF C and TSF D) is also expected to report to Davidson Creek downstream of the FWR. During Operations, water from Tatelkuz Lake will be used to provide instream flow needs to Davidson Creek.

Turtle Creek and Creek 661 are parallel drainages to Davidson Creek that also flow northeast to Chedakuz Creek. Creek 661 is at the south of the footprint and connects to Chedakuz Creek upstream of Tatelkuz Lake, a tributary of Creek 661 is located within the footprint of mining facilities, including a portion of the proposed Open Pit and potentially may receive seepage from the TSF. Turtle Creek is at the north of the footprint and enters Chedakuz Creek, approximately 2 km downstream of Davidson Creek. No mining facilities are located in this watershed; however, the airstrip and limited portions of the proposed mine access road will be located within the Turtle Creek watershed.

Upstream of potential mine influence on the Chedakuz Creek is Kuyakuz Lake which is considered a control site.

FIGURE 1.7-1 STUDY AREA FOR AQUATIC EFFECTS MONITORING PROGRAM



ERM

CLIENT: BW Gold LTD.
GIS NUMBER: BLW-01-042-03

DATE: 03/11/2026

PROJECTION: NAD 1983 UTM Zone 10N
SCALE: 1:125,000 when printed at 11x17

There will be no Mine infrastructure or mining facilities located in the Fawnie Creek watershed. Thus, Fawnie Creek sampling locations are considered control sites.

Creek 705 is located on the southern side of a topographic divide from the aforementioned catchments and flows southwest to Fawnie Creek. Creek 705 will receive diverted flows from the headwaters of Lake 1682. No Mine discharge or seepage is predicted to report to Creek 705 and no changes in water quality were predicted. Therefore, Creek 705 is considered to be a control site for surface water and aquatic resource components. Hydrology monitoring is also completed at Creek 705 to confirm predictions (i.e., Chapter 5 of BW Gold [2022] indicated that there will be an increase in flow of 10 L/s on an average annual basis at all locations on Creek 705 as a result of diverted flows from the headwaters of Lake 1682).

1.7.2 COMPONENTS INCLUDED IN THE AQUATIC EFFECTS MONITORING PROGRAM

The 2025 AEMP was implemented in accordance with AEMP Plan, Version 4.0 (the AEMP Plan; ERM 2025b) which incorporated the recommendations from the 2024 AEMP Interpretive Report, and comments from BC Ministry of Environment Parks (BC ENV), BC Ministry of Water, Land and Resource Stewardship (BC WLRS), Environmental Assessment Office (EAO) and Indigenous groups. A draft update to the AEMP Plan, Version 3.0 was provided for review in December 2024 based on communications with stakeholders. Upon approval of the AEMP Plan, Version 3.1 (letter to BW Gold, dated April 30, 2025), the following BC ENV conditions of approval were incorporated into the next version (4.0) of the AEMP Plan:

1. *The permittee must conduct kokanee fry outmigration sampling at the frequency of every other night for the duration of the peak outmigration period.*
2. *The permittee must conduct a power analysis, using data collected in 2023, 2024, and 2025, to determine the frequency of mark recapture sampling needed on kokanee fry outmigration.*
3. *The permittee must report all fish mortalities under the AEMP by species, cause of mortality, and type of sampling in the subsequent AEMP Interpretive Reports.*
4. *The permittee must collect PAH samples in sediment during the 2025 sampling program to establish baseline at sites 661-01, 661-05, 661-10, DC-05, DC-15, TC05, and 705-05. Analysis and discussion of PAH concentrations in sediment must be included in the 2025 AEMP Interpretive Report.*
5. *The permittee must update all maps and figures with the current and proposed sampling activities and include them within future versions of the AEMP Plan.*
6. *The permittee must use statistical analysis where covariates can be accounted for when completing fish tissue analysis.*

To the extent feasible implementation of key changes to the program were completed in 2025, and full implementation of the AEMP Plan, Version 4.0 (including recommendations following completion of the 2024 interpretive report) occurred as part of the 2025 AEMP.

The following components of the aquatic ecosystem were monitored during the 2025 reporting period and assessed in this report as indicated in the AEMP Plan (ERM 2025b):

- Surface water quality, and chronic toxicity testing;
- Sediment quality;

- Aquatic primary producers and benthic invertebrates (referred to as aquatic resources);
- Benthic invertebrate tissue metals; and
- Fish community, fish tissue metal sampling, and fish spawning.

An assessment of hydrology and water temperature was also completed during the 2025 reporting period and are reported under a separate cover (KP 2026a).

As outlined in the AEMP Plan (ERM 2025b) sediment toxicity testing and water dependent wildlife monitoring are only completed if triggered through the adaptive management response framework. Sediment toxicity testing was not triggered following the completion of the 2024 evaluation of the sediment quality response framework (ERM 2025a) and therefore was not completed during the 2025 reporting period. There were no water-dependent wildlife studies additional to those already outlined in the WMMP completed during the 2025 reporting period following the evaluation of the 2024 water quality response framework (ERM 2025a).

1.7.3 SAMPLING SITES AND FREQUENCY

In general, the sampling sites for the AEMP have been selected and grouped (Table 1.7-1) to enable the identification of the Mine-related effects (near-field sites, immediately downstream of the mine site in Davidson Creek or Creek 661), as well as mid- and far-field sites to enable identification of potential interactions of Mine effects with other, non-mining-related effects (e.g., cumulative effects, such as from logging or agricultural activities). If changes in the aquatic environment are identified in mid- or far-field sites, but not at near-field sites, the changes are unlikely to be due to the Mine-related effects. If changes in the aquatic environment are identified in near-field sites, particularly the sites closest to the mine site, the changes are likely attributed to the Mine. In this case, a gradient analysis (either statistically or through visual data exploration) will be completed to identify the extent of the Mine-related effects.

Sampling components at each site have been selected based on the likelihood and magnitude of potential impacts, suitability for sampling (i.e., aquatic resource or other instream sampling are not completed in areas of Kokanee spawning habitat to avoid causing damage or disruption to bed substrates), and the requirement for control sites (Table 1.7-2; Figures 1.7-2 to 1.7-6).

Water quality is characterized by monthly water quality sampling conducted at control sites in addition to near-field impact sites expected to receive the Mine contact water (seepage) or discharge (stream sites Figures 1.7-2 and 1.7-3; Tables 1.7-2 and 1.7-3). Quarterly sampling of stream water quality at mid-field and far-field impact sites is completed to capture variability during both the ice-covered season (November and February) and open water season (May and August). Quarterly sampling of lake water quality (open water and littoral zone sites) also is completed to capture seasonal variability, with samples to be collected in the winter ice-covered season (February), spring/summer open water (May and August), and late fall open water (October or November). Weekly or 5-in-30 water quality sampling (where 5 water samples are collected in a 30-day period instead of the monthly or quarterly sample) is completed once in May/June and once in September/October at a subset of sites to characterize water quality during the most variable periods of the year (freshet and fall rains, when guideline exceedances are most likely to occur). The 5-in-30 sampling is focused primarily on Davidson Creek and Chedakuz Creek sites (Table 1.7-2).

TABLE 1.7-1 AQUATIC EFFECTS MONITORING PROGRAM STREAM AND LAKE SAMPLING SITES AND RATIONALE

Watershed	Site ID (PE 110652 ID)	Easting	Northing	Type of Site	Rationale
Streams					
Davidson Creek	DC-05 (E331279)	378205	5899299	Near-field impact site	• Approximately 140 m downstream of FWR reservoir discharge • 3.4 km downstream of TSF Stage 1 SCP discharge • Downstream of seepage
	DC-10 (E331280)	378845	5900157	Near-field impact site	• Approximately 100 m downstream of Downstream Aggregate Borrow Area SCP discharge • 1.4 km downstream of downstream of FWR reservoir • Downstream of seepage
	DC-15 (E331281)	381880	5904054	Near-field impact site	• 7.9 km downstream of FWR reservoir discharge • 6.6 km downstream of Downstream Aggregate Borrow Area SCP discharge • Downstream of seepage
	DC-20 (E331281)	384234	5907722	Mid-field impact site	• 14.2 km downstream of FWR reservoir discharge • 13.0 km downstream of Downstream Aggregate Borrow Area SCP discharge • Downstream of seepage • 1.2 km upstream of the confluence with Chedakuz Creek
Turtle Creek	TC-01 (E331283)	369772	5902753	Control site (upstream control site)	• Control site upstream of the airstrip on Turtle Creek
	TC-05 (E331284)	376375	5904723	Near-field impact site	• Downstream and downwind of the airstrip
	TC-10 (E331285)	379129	5906160	Mid-field impact site	• Downstream and downwind of the airstrip
	TC-15 (E331286)	383300	5908691	Mid-field impact site	• Downstream and downwind of the airstrip • Adjacent to access road

Watershed	Site ID (PE 110652 ID)	Easting	Northing	Type of Site	Rationale
Creek 661–Mainstem	661-01 (E331287)	378620	5894431	Control site (upstream control site) for water quality, sediment, aquatic resources, and fish only	• Control site on mainstem Creek 661, upstream of confluence with Creek 543585
	661-02 (E331288)	380977	5897748	Control site (upstream control site) for hydrology and water temperature only	• Mainstem Creek 661, 160 m upstream of the confluence with Creek 505659
	661-10 (E331289)	381179	5897915	Near-field impact site	• Downstream of seepage
	661-20 (E331290)	388662	5899439	Mid-field impact site	• 370 m upstream of the Creek 661 confluence with Chedakuz Creek • Downstream of seepage
Tributary of Creek 661–Creek 543585	661-03 (E331291)	380803	5897193	Near-field impact site on Creek 543585	• Downstream of groundwater seepage from the Camp Site
Tributary of Creek 661–Creek 146920	661-04 (E331292)	378714	5896389	Near-field impact site on Creek 146920	• Downstream of groundwater seepage from the Camp Site
Tributary of Creek 661–Creek 505659	661-05 (E331293)	378843	5897007	Near-field impact site on Creek 505659	• Downstream of seepage
	661-09 (E331294)	381129	5897914	Near-field impact site on Creek 505659 (hydrology and water temperature only)	• Downstream of seepage

Watershed	Site ID (PE 110652 ID)	Easting	Northing	Type of Site	Rationale
Chedakuz Creek	CC-03 (E331295)	388645	5899175	Control site (upstream control site) for water quality only	• Control site on Chedakuz Creek, 300 m upstream of the confluence of upper Chedakuz Creek and Creek 661 • Identified as CC-02 for Kokanee spawning sampling
	CC-05 (E331296)	389737	5900563	Mid-field impact site	• 1.8 km downstream of the confluence of upper Chedakuz Creek and Creek 661 • Upstream of inflow to Tatelkuz Lake • Downstream of seepage to Creek 661
	CC-10 (E331297)	385418	5907732	Mid-field impact site	• At outflow of Tatelkuz Lake • Downstream of seepage to Creek 661
	CC-12 (E331298)	385080	5908171	Mid-field impact site (Hydrology and water temperature only)	• 100 m upstream of the confluence of Davidson Creek and Lower Chedakuz Creek • Downstream of seepage
	CC-15 (E331299)	383924	5909393	Mid-field impact site	• 18.1 km downstream of FWR reservoir • 2.7 km downstream of confluence with Davidson Creek • 1.0 km upstream of Turtle Creek confluence • Downstream of seepage • Adjacent to access road and upstream of the bridge
	CC-20 (E331300)	383097	5910077	Far-field impact site	• 19.1 km downstream of FWR reservoir • 3.9 km downstream of confluence with Davidson Creek • Downstream of seepage
	CC-30 (E331301)	375187	5916462	Far-field impact site	• 40.0 km downstream of FWR reservoir • 16.2 km downstream of private properties located near Tatelkuz Lake • Downstream of seepage
	CC-40 (E331302)	368695	5918685	Far-field impact site	• 52.9 km downstream of FWR reservoir • 2.3 km upstream of the confluence of with the Nechako Reservoir • Downstream of seepage

Watershed	Site ID (PE 110652 ID)	Easting	Northing	Type of Site	Rationale
Creek 705	705-05 (E331303)	365887	5894321	Control site (regional control site)	• Regional control site for Davidson Creek • 7.4 km downstream of Lake 1682 • 7.1 km upstream of confluence with Fawnie Creek
	705-10 (E331304)	362169	5892943	Control site (regional control site)	• Regional control site for Davidson Creek • 11.5 km downstream of Lake 1682 • 3.0 km upstream of confluence with Fawnie Creek
Fawnie Creek Tributary	FC-01 (E331305)	363860	5899323	Control site (regional control site)	• Regional control site for Davidson Creek • 1.6 km upstream of confluence with Fawnie Creek
Mathews Creek	MC-05 (E331306)	358247	5886498	Control site (regional control site) for hydrology and water temperature only	• Regional control site located in an adjacent watershed, upstream of confluence with Fawnie Creek
Lakes					
Kuyakuz Lake	KL-01 (E331307)	395187	5888710	Control site (upstream control site)	• Control lake located in upper Chedakuz Creek, upstream of the confluence with Creek 661
Tatelkuz Lake	TL-01 (E331308)	386010	5906768	Mid-field impact site (water quality and fish tissue only)	• Lake located at the terminus of upper Chedakuz Creek • Downstream of seepage to Creek 661
	TL-01H (E331309)	387946	5905964	Mid-field impact site (water level and temperature only)	
	TL-02 (E331310)	389691	5902565	Mid-field impact site (water only)	• Littoral zone sampling site to monitor for seepage-influenced groundwater in Tatelkuz Lake
	TL-03 (E331311)	387466	5905141	Mid-field impact site (water only)	• Littoral zone sampling site to monitor for seepage-influenced groundwater in Tatelkuz Lake
	TL-04 (E331312)	385302	5906861	Mid-field impact site (water only)	• Littoral zone sampling site to monitor for seepage-influenced groundwater in Tatelkuz Lake

Notes:
Per Appendix B (Receiving Environment Monitoring Program) and Appendix C (Aquatic Effects Monitoring Program) in PE-110652.
Dashes indicate sampling component is not completed at that site.
[1] A continuous hydrology monitoring station will be installed at selected locations unless indicated as manual flow measurements or a water level station at TL-01H (see KP 2026a).
[2] 5-in-30 water sampling refers to the collection of 5 water samples in 30 days during spring freshet and fall rains high flow periods and replaces the monthly or quarterly sample during the month(s) when the 5-in-30 samples are collected.
[3] At each of the site IDs indicated a minimum of two reach/site IDs are surveyed–DC-05 (Reach ID DC-1A and DC-3), 661-20 (Reach ID 661-20A, 661-20B, 661-20C, 661-20D, 661-20E, 661-20F, 661-20G, and 661-20H), CC-02 (Reach ID CC-02A and CC-02B), CC-05 (Reach ID CC-05A and CC-05B), and CC-15 (Reach ID CC-15A and CC-15B) (Section 4.8.2).
[4] Aquatic resources include primary producer sampling (biomass and taxonomy, Section 5), and benthic invertebrate sampling (abundance and CABIN/taxonomy, Section 6).

TABLE 1.7-3 AEMP SAMPLING FREQUENCY AND REPLICATION

Monitoring Component	Annual Frequency	Monthly Frequency or Time of Year	Replication and Depths at Each Stream/Lake Sampling Event
Streams			
Automated hydrometric stations	Annual	Permanent installation with telemetry allowing real-time data download	n = 1
Manual flow measurements	Annual	Manual flow measurements, minimum of five per year with one winter flow measurement per year	n = 1
Water temperature	Annual	Permanent installation with telemetry allowing real-time data download	n = 1
Water quality	Annual	Monthly	n = 1, plus quality control (QC) samples at 20% of all samples collected within 48 hours of each other[2]
	Annual	Quarterly	n = 1, plus QC samples at 20% of all samples collected within 48 hours of each other[2]
	Annual	5-in-30 samples during freshet and fall rains	n = 5, plus QC samples at 20% of all samples collected within 48 hours of each other[1]
Chronic toxicity testing	Annual for the first three years	Late August–Early September	n = 1
Sediment quality	Annual for the first three years	Late August–Early September	n = 5, plus 10% field duplicate samples
Periphyton biomass and taxonomy	Annual for the first three years	Late August–Early September	n = 5
Benthic invertebrates	CABIN annual for the first three years	Late August–Early September	Abundance, n = 1 Taxonomy, n = 1, plus a duplicate sample
Benthic invertebrate tissue metals	Once per three years	Late August–Early September	n = 5
Fish community–summer inventory of the fish community	Annual for the first three years	After late July or early August	n = 10 rainbow trout per size class
Fish tissue metals	Annual for the first three years	After late July or early August	n = 8 rainbow trout
Fish community–kokanee summer spawning survey	Annual for the first eight years	Mid-July–Late September	Weekly counts

Monitoring Component	Annual Frequency	Monthly Frequency or Time of Year	Replication and Depths at Each Stream/Lake Sampling Event
Fish community–kokanee fry spring outmigration survey	Annual for the first eight years	Early spring (freshet)	Regular intermittent sampling throughout outmigration period Mark-recapture over multiple two-night sample events during outmigration period
Fish community–rainbow trout spring spawning survey	Annual for the first eight years	Mid-April–Late June	Daily trap checks
Lakes			
Water level	Annual	Permanent installation with telemetry allowing real-time data download	n = 1
Water quality for lake limnetic zone	Annual	Quarterly	n = 3 (surface, mid-depth, and near bottom), plus QC samples at 20% of all samples collected within 48 hours of each other[1]
Water quality for lake littoral zone	Annual	Quarterly	n = 1, plus QC samples at 20% of all samples collected within 48 hours of each other[1]
Fish tissue in Tatelkuz Lake–rainbow trout, mountain whitefish, and kokanee. Fish tissue in Kuyakuz Lake–rainbow trout and mountain whitefish.	Once per three years	Late August–Early September	n = 8 of each species

[1] Per Condition 4.10.3 of EMA Permit PE-110652.

For sites where surface water quality monitoring data is used for the purposes of comparison with Yinka Dene Water Law (YDWL) standards the water quality sampling frequency has been set at monthly with 5-in-30 sampling. The proposed standards were identified for DC-05 in Davidson Creek and CC-15 in Chedakuz Creek (Artemis 2023). For the control site located in upper Chedakuz Creek (CC-03), sampling frequency is also set at monthly with 5-in-30 sampling. For other water quality sampling sites in Chedakuz Creek, the sampling frequency has been set to quarterly.

1.7.4 SPECIAL STUDY—HYDROCARBONS

Sampling of sediment polycyclic aromatic hydrocarbons (PAHs) was completed in accordance with the BC ENV conditions of the approval of the AEMP Plan, Version 3.1 (letter to BW Gold, dated April 30, 2025). Sediment samples were collected at each of the required sites following the same methods for AEMP sediment quality sampling (Section 4.2.1) and results are discussed in Section 4.3.3.

1.8 ADAPTIVE MANAGEMENT

The AEMP Plan, Version 4.0 provided a Response Framework for the sampling components (water quality, sediment quality, periphyton, aquatic invertebrate, and fish tissue metal) that adopted the new guidance.

Numeric performance metrics (NPMs) are defined as the thresholds for determining adaptive management action levels (equivalent to "qualitative and quantitative triggers" described in EAC Condition 3(g) for adaptive management). Figure 1.8-1 identifies the components of the adaptive management framework.

FIGURE 1.8-1 ADAPTIVE MANAGEMENT FRAMEWORK

Plan (Assess and Design)—The AEMP study design considered planned mitigation and management measures and the requirements for AEMPs to meet EAC Condition 30. BW Gold has engaged, and will continue to engage, throughout all phases of the Mine with Indigenous groups and relevant federal and provincial authorities on these measures and programs.

Do (Implement)—Implementing the mitigation measures as described in Mitigation and Management Plans for the Mine.

Monitor—Section 4 of the AEMP Plan (ERM 2025b) includes monitoring programs to determine if, after mitigations and management has been applied, the Mine-related effects on the aquatic receiving environment occur.

BW Gold will review and update monitoring programs, including the AEMP, as required during the life of the Mine. This will include:

- Review of the monitoring program in terms of its sensitivity to detect effects.
- Recommendations provided by a Qualified Professional for changes to the monitoring plan, objectives, frequency, methods, or timing.
- Engagement tracking to record input from Indigenous groups and regulators such as the EAO and ENV.

Adjust (Evaluate and Adjust)—NPMs relative to baseline conditions, predicted conditions, and other benchmarks such as water, sediment, and tissue quality guidelines, were developed, to determine whether mitigation measures need to be altered or additional mitigation measures implemented.

The NPMs were provided at the following action levels of the adaptive management framework: "none", "low", "medium", and "high". The framework is intended to provide an early-warning system such that when defined action level NPMs are exceeded there is sufficient time to identify the cause of unexpected changes and modify existing or implement new mitigation measures to prevent irreversible adverse effects.

The NPM thresholds for each of the action level considers the following questions:

- Are AEMP component assessment endpoints changing in ways that were not predicted by models or is mitigation less successful than anticipated (e.g., concentrations of parameters in water higher than predicted by the surface water quality model)?
- Are AEMP component assessment endpoints at impact sites changing from baseline conditions or reference ranges (e.g., concentrations higher than the baseline conditions or reference ranges) as a result of the Mine?
- Are AEMP component assessment endpoints at impact sites changing to levels that have the potential to cause adverse effects (e.g., exceeding a WQG or other benchmark) as a result of the Mine activities?

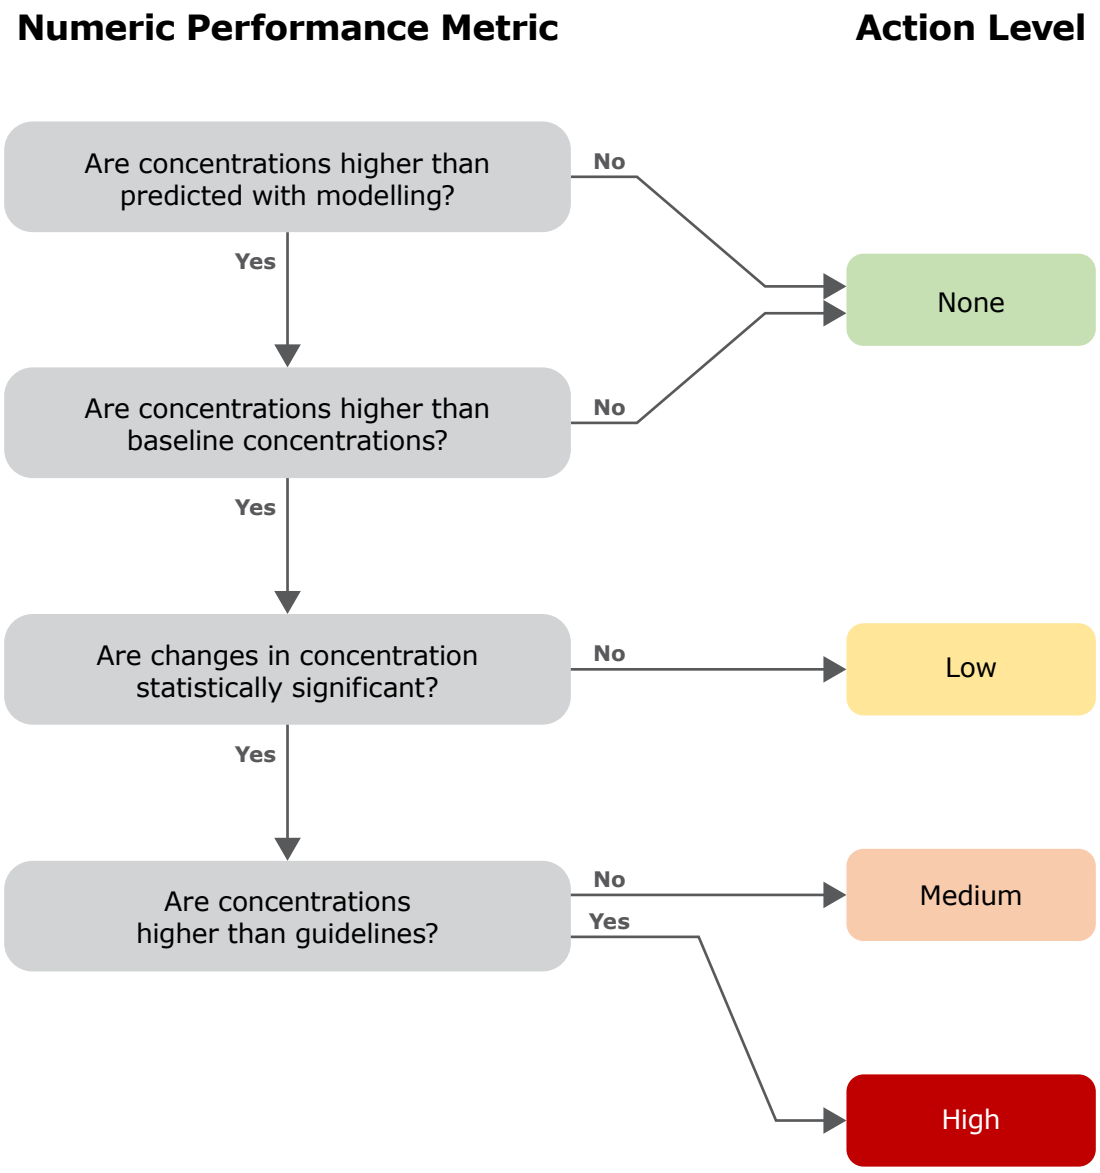
Figure 1.8-2 depicts the questions and general approach to determining the management action level based on the results of AEMP monitoring relative to NPM thresholds.

At the "none" action level, the results of monitoring are lower than NPM thresholds for predicted conditions or baseline conditions and are lower than applicable guidelines (Figure 1.8-2). At the "none" action level, mitigation measures are assumed to be working as expected since the results of monitoring are within the range of what was predicted to occur or are similar to baseline conditions.

At the "low" or "medium" action level differences have been identified between monitoring results and NPM thresholds for predicted conditions or baseline conditions but guidelines are not exceeded (Figure 1.8-2). The statistical significance of results between near-field and control sites is used to determine whether the action level is "low" (no significant differences) or "medium" (significant differences). At both the "low" and "medium" action levels, confirmation of effects and investigation of the root cause of effects are critical foundational management actions that will dictate what additional actions may be required to stabilize or reverse unexpected trends and prevent adverse effects. Acting before reaching the "high" action level will allow time for the refinement of existing mitigation measures or the identification, development, and implementation of new mitigation measures before adverse effects may occur.

At the "high" action level, results of monitoring indicate that guidelines or other indicators for potential adverse effects have been exceeded, and monitoring results are higher than both NPM thresholds for predicted conditions and are outside of the range of baseline conditions (Figure 1.8-2). At this action level, mitigation measures are not performing as expected (and thus require adjustment) or additional new mitigation measures are required so that adverse effects do not occur.

FIGURE 1.8-2 FLOW DIAGRAM OF NUMERIC PERFORMANCE METRICS AND ACTION LEVELS



The evaluation of the Response Framework for surface water quality, sediment quality, periphyton and nutrients, aquatic invertebrate and fish tissue metals is provided in Sections 2.4, 4.4, 5.4, 6.4, and 7.4 for Construction and Operations (October 1, 2022 to December 31, 2025).

The Trigger Response Plan for Authorized Discharges to Davidson Creek (the TRP), developed per PE-110652 Condition 3.4 for discharges from the FWR and the Downstream Aggregate Borrow Area Sediment Control Pond, was submitted per PE-110652 for review on June 6, 2025. Comments were received from ENV and Source Environmental Associates Inc. on behalf of the NFNs, and BW Gold submitted an updated version of the TRP in response to review comments on December 9, 2025. The TRP submitted by BW Gold to ENV for approval in December 2025 was not approved by the end of 2025.

2. SURFACE WATER QUALITY

2.1 MEASUREMENT AND ASSESSMENT ENDPOINTS

Surface water quality was evaluated with one or more assessment endpoints including graphical analysis, reference ranges, before-after-control-impact (BACI) analysis, and/or comparison to water quality guidelines for the protection of freshwater aquatic life (BC WLRS 2025a and 2025b; Canadian Council of Ministers of the Environment [CCME] 2024a), approved SBEBs (BC ENV 2023a), and the YDWL water quality standards (Table 2.1-1).

TABLE 2.1-1 MEASUREMENT AND ASSESSMENT ENDPOINTS FOR 2025 AQUATIC EFFECTS MONITORING PROGRAM COMPONENTS

Measurement Endpoint	Assessment Endpoint
Surface water quality parameters	• Graphical comparison to baseline data • Graphical comparison to baseline ranges[1] • Before-after-control-impact (BACI) analysis[2] • Comparison to water quality model predictions • Comparison to BC or CCME Water Quality Guidelines (BC WLRS 2025a, 2025b; CCME 2025a), approved Science-Based Environmental Benchmarks (BC ENV 2023), and proposed Yinka Dene Water Law water quality standards

Notes:
[1] For in situ water quality parameters: pH, temperature, turbidity (stream sites and lake sites TL-02, TL-03, and TL-04), conductivity, and dissolved oxygen.
[2] For water quality parameters analyzed at the laboratory: total suspended solids, total dissolved solids, pH, alkalinity, total phosphorus, ammonia-N, nitrate-N, nitrite-N, chloride, fluoride, sulphate, cyanide (total and weak acid dissociable), total metals including aluminum, antimony, arsenic, barium, beryllium, boron, cadmium, chromium, cobalt, copper, iron, lead, manganese, mercury, molybdenum, nickel, selenium, silver, strontium, thallium, uranium, vanadium, and zinc; dissolved metals including aluminum, cadmium, calcium, copper iron, manganese, and zinc.

2.2 SAMPLING SITES AND METHODS

As defined in the AEMP Plan (ERM 2025b), surface water quality samples were collected at sites downstream from the Mine and control sites, as indicated in Table 1.7-2, at the frequencies identified in Table 1.7-3.

2.2.1 FIELD METHODS

BW Gold completed the collection of stream and lake water quality samples. Sampling methods followed best practices as outlined in the *British Columbia Field Sampling Manual* (BC MWLAP 2013). Samplers practiced clean sampling techniques including wearing clean vinyl gloves while handling samples at each site.

For stream sampling, water samples were collected in areas of laminar flow (if present and when it was safe to do so) to avoid suspended particulates. Stream samples were collected by facing upstream and submerging the laboratory-certified, clean general parameter sample bottle below

the surface until filled. The general parameter bottle was used to fill the other sample bottles by decanting the collected water. For lake sampling at KL-01 and TL-01, discrete samples were collected at three depths in the water column (i.e., hypolimnion, metalimnion, and epilimnion) using a Van Dorn water sampler. Lake water quality sampling completed at the littoral zone sites (TL-02, TL-03, and TL-04) was completed for only a single shallow depth.

In situ water measurements were also taken using a calibrated multi-parameter meter (e.g., YSI Professional Plus or similar equipment) to obtain field readings for physical parameters (pH, temperature, turbidity, conductivity, and dissolved oxygen) at the stream sites and lake sites TL-02, TL-03, and TL-04. Physical parameters (pH, temperature, conductivity, and dissolved oxygen) were measured at approximately 1 m intervals at the lake sites TL-01 and KL-01.

All samples were field-filtered and/or preserved in the field according to the analytical laboratory protocols. Samples were stored in coolers on ice and/or refrigerated until shipped to ALS Laboratory (ALS; Burnaby, BC), a Canadian Association for Laboratory Accreditation (CALA)-certified laboratory for analysis.

2.2.2 LABORATORY METHODS

Water quality samples were collected for analysis of general physical/ion parameters, nutrients and organics, cyanide, and total and dissolved metals at ALS. The water quality parameters were analyzed using standard methodologies, as recommended by BC Ministry of Environment (BC MOE; 2016a). Targeted method detection limits (DL) for parameters were at least 10 times lower than water quality guidelines or standards, where available, consistent with recommendations in BC MOE (2016a). Parameters analyzed are provided in Table 2.2-1.

TABLE 2.2-1 ANALYZED WATER QUALITY PARAMETERS

Physical Parameters and Dissolved Anions	Nutrients/Cyanides/ Organic Carbon	Metals (Total and Dissolved)	
• temperature (field) • dissolved oxygen (field) • pH (field and laboratory) • total alkalinity (as $CaCO_3$) • acidity (as $CaCO_3$) • conductivity (field and laboratory) • hardness (as $CaCO_3$) • total dissolved solids • turbidity (field and laboratory) • total suspended solids • bromide • chloride • fluoride • sulphate	• ammonia-N • nitrate-N • nitrite-N • Total Kjeldahl Nitrogen • total phosphorous • ortho-phosphorus • total cyanide • cyanide, weak acid dissociable • thiocyanate • total organic carbon • dissolved organic carbon	• aluminum • antimony • arsenic • barium • beryllium • bismuth • boron • cadmium • calcium • chromium • cobalt • copper • iron • lead • lithium • magnesium	• manganese • mercury • molybdenum • nickel • potassium • selenium • silicon • silver • sodium • strontium • thallium • tin • titanium • uranium • vanadium • zinc

2.2.3 QUALITY ASSURANCE/QUALITY CONTROL

The quality assurance/quality control (QA/QC) principles for surface water quality sampling followed those outlined in guidance documents for the field sample collection phase (BC MOE 2016a; Environment Canada 2012a; BC MWLAP 2013; BC ENV 2023b). Standard QA/QC practices included water quality samples being collected by qualified personnel using suitable sampling equipment and Chain-of-Custody (COC) forms were used to track the samples.

The QA/QC procedures for the measurement of field (*in situ*) parameters included daily calibration of the meter before use, as per the manufacturer's manual and recorded in a calibration log. The meter was allowed to stabilize before taking each reading and the data was reviewed for unreasonable values.

The QA/QC field blanks, travel blanks, and field duplicates were collected as indicated in Section 4.10 (Quality Assurance) of PE-110652: the number of QC surface water samples should be 20% of all samples collected (environmental and QC samples) within each sampling event (or within 48 hours of each other), and include field duplicate, field, and travel blank samples for each parameter. Field duplicate samples were collected in the field at randomly selected stations and submitted to the laboratory to indicate the variability inherent in field sampling (i.e., environmental heterogeneity). Field blanks are empty sample bottles filled with deionized water at randomly selected stations to assess potential contamination from the surrounding environmental conditions (e.g., aerial particulates) and sample handling techniques. Travel blanks are pre-filled by the analytical laboratory and are not opened in the field to assess potential contamination from travel, storage, or from laboratory handling.

Water quality laboratory analyses were conducted by a CALA-certified laboratory. The QA/QC principles for surface water quality laboratory analysis followed those outlined in guidance documents throughout the laboratory analysis phase (BC MOE 2016a; Environment Canada 2012a; BC MWLAP 2013; BC ENV 2023b). Laboratory QA/QC measurements and protocols were completed to determine and confirm the accuracy, sensitivity, precision, and comparability of the data, as recommended by BC ENV (2020a). This included evaluation of holding times, the use of method blanks, replicates, laboratory control samples and reference material, and matrix spikes. Method blanks are clean control samples that detect potential contamination during sample preparation and analysis. Laboratory duplicates are field-collected samples split at the laboratory and analyzed separately. Method blanks and laboratory duplicates determine methodological precision. Accuracy was tested using laboratory control samples, reference materials, and matrix spikes. Laboratory control samples are a clean matrix (i.e., distilled, de-ionized water) spiked with test parameters. Reference materials are samples with a known concentration of a parameter. Matrix spikes are field-collected samples that are spiked with test analytes. Anomalous results (for example, detected concentrations in the blanks) were verified by the laboratory with repeated analysis.

2.2.4 DATA ANALYSIS

For the purpose of calculating summary statistics and presentation, concentrations below the DL were replaced with half the DL (BC MOE 2016b).

2.2.4.1 STUDY QUESTION 1- COMPARISON TO BASELINE

Water quality samples were collected beginning in 2011, however, only the 2016 to 2022 observations were utilized as the baseline years for the comparison to baseline and assessment of Mine-related effects because a different laboratory was used to analyze surface water quality in earlier sampling programs (see ERM 2023). Comparison to baseline focused on the list of evaluated parameters identified in the AEMP Plan (ERM 2025b):

- For *in situ* water quality parameters: pH, temperature, turbidity (stream sites and lake sites TL-02, TL-03, and TL 04), conductivity and dissolved oxygen.
- For water quality parameters analyzed at the laboratory: pH, total alkalinity, total dissolved solids (TDS), TSS, total phosphorus, ammonia-N, nitrate-N, nitrite-N, chloride, fluoride, sulphate, cyanide (total and weak acid dissociable), total metals including aluminum, antimony, arsenic, barium, beryllium, boron, cadmium, chromium, cobalt, copper, iron, lead, manganese, mercury, molybdenum, nickel, selenium, silver, strontium, thallium, uranium, vanadium, and zinc; dissolved metals including aluminum, cadmium, copper, iron, manganese, and zinc.

Dissolved cobalt was also included as an evaluated parameter in response to the Level 3 trigger concentrations established in the Draft Groundwater Trigger Response Plan for Non-Point Source Discharges to Ground.

Potential Mine-related effects on stream field parameters (pH, temperature, conductivity, and dissolved oxygen) were assessed by graphical analysis, to determine if monthly means during construction and operations (October 2022 to December 2025) were outside the typical range observed during baseline (i.e., 5th to 95th percentile values/concentrations for the 2016 to September 2022 period). Field turbidity was not measured during baseline sampling therefore a comparison of turbidity measures at potential impact sites to control sites was completed.

Potential Mine-related effects on lake profile field parameters (pH, temperature, conductivity, and dissolved oxygen) were assessed by graphical analysis, to determine if profiles during construction and operations (October 2022 to December 2025) differed from baseline (2016 to September 2022).

Potential Mine-related effects on streams were investigated using BACI analysis (R Core Team 2025), on the following receivers that were directly downstream of construction activities and surface water discharges to Davidson Creek:

- Davidson Creek watershed (DC-05, DC-10, DC-15, and DC-20)
- Creek 661 watershed (661-03, 661-04, 661-05, 661-10, and 661-20)
- Chedakuz Creek watershed (CC-05, CC-10, CC-15, CC-20, CC-30, and CC-40)

The parameters selected for BACI analyses were limited to parameters where the mean monthly concentration during the construction and operations (October 2022 to December 2025) was greater than the corresponding monthly 95th percentile baseline concentration plus 20% for two or more consecutive months. For pH comparison to baseline, the hydrogen ion concentrations were used to calculate the 5th and 95th percentile baseline range for comparison to mean monthly pH observed during construction activities.

Data transformations (e.g., log transformation) were completed if determined to be appropriate (e.g., to achieve random distribution of residuals). For all effects analyses, statistical results were considered unreliable if more than 70% of the values in the dataset for a parameter are below DL (i.e., highly censored data).

The BACI analysis introduces a class effect to a mixed model Analysis of Variance (ANOVA), which is based on the classification of a site as an impact or a control site. The mixed model ANOVA also included the fixed effect of period ("before" versus "after"), and random effects of year, month, and site to account for variability across sites and in water quality data. For the period effect, data were grouped into one of two periods: before the start of construction activities (2016 to September 2022) or after construction and operations (October 2022 onwards).

A significant interaction between the (time) period and class effects reveals whether any before (baseline) - after (Construction phase) change in the mean parameter concentration that occurred in the exposure site has not occurred in the control site. The overall site (control versus impact) and period ("before" versus "after") interaction significance (p-value less than significance level [α] of 0.05) was assessed using an F-test. To reduce the number of false positives (Type I error) due to the large number of statistical tests conducted, a multiple test correction was applied to the significance level of 0.05.

It is hypothesized that if mine activities affected surface water quality, then there would be a significant change in surface water quality at near-field impact sites in comparison with baseline concentrations or control sites. However, if a change in the mean is detected by the before-after comparison, but the BACI analysis indicates that a parallel change also occurred at the control site (control versus impact), it is reasonable to conclude that this change is likely a natural phenomenon or unrelated to the Mine activities. Similarly, if a change is detected at mid- or far-field sites but not at near-field sites or the control site, it is reasonable to conclude that this change is likely the result of non-Mine related activities (e.g., wildfire, forestry, or agricultural activities downstream of the Mine and upstream of the sampling site).

To support the interpretation of the mixed model ANOVA, a post-hoc power analysis was conducted to determine the observed power for the fixed effects in the repeated-measures ANOVA at a 95% significance level (alpha = 0.05). In this statistical framework, "power" refers to the model's capacity to accurately reject a false null hypothesis.

A precautionary approach was used to determine if an effect is attributable to the Mine activities in cases of unexplained significant interactions using professional judgement, and/or field data to confirm significantly greater or lower concentrations

2.2.4.2 STUDY QUESTION 2 – COMPARISON TO MODEL PREDICTIONS

Observations from receiving environment monitoring sampling sites that were included as modelling nodes in the surface water quality predictive model were used to evaluate the assumptions integrated into the model (i.e., comparison of measured concentrations to modelled predictions). Monitoring sites that were also model nodes include (model node names in brackets): DC-05 (WQ28), DC10 (WQ27), DC-15 (WQ26), and DC-20 (WQ7) in Davidson Creek;

661-05 (WQ3), 661-10 (WQ5) and 661-20 (WQCreek661) in Creek 661; and CC-10 (WQ8), CC-15 (WQ9), and CC-20 (WQ13) in Chedakuz Creek.

Comparison of measured concentrations to water quality model predictions was completed as part of the adaptive management response framework for surface water quality described in Section 2.4. Comparison of measured and predicted concentrations is also expected as part of Annual Reporting under the EMA Waste Discharge Authorization for effluent (BC MOE 2016b). Where the surface water quality model is found to over-predict or under-predict concentrations of parameters at a particular site, additional evaluation will be completed to identify if adjustments to the model are required. Over time, incorporation of additional Mine-specific information and site understanding will result in refinement of the water quality model to improve the accuracy of future predictions.

2.2.4.3 STUDY QUESTION 3—COMPARISON TO WATER QUALITY GUIDELINES, SCIENCE-BASED ENVIRONMENTAL BENCHMARKS, AND STANDARDS

Surface water parameter concentrations were compared to BC (BC WLRS 2025a, 2025b) or federal (CCME 2025a) Water Quality Guidelines for the Protection of Aquatic Life (WQG-AL); approved SBEBs; and the YDWL water quality standards (Artemis 2023). Concentrations that were less than the DL, but the DL was greater than the applicable guidelines, benchmarks, and/or standards were noted but excluded from exceedance calculations.

Comparisons of measured parameter concentrations to WQG-ALs (Table 2.2-2) follows the hierarchy provided in Technical Guidance 4: Annual Reporting under the *Environmental Management Act* (BC MOE 2016b). Comparisons to the WQG-AL were completed for the mean of monthly samples and the mean of five weekly (5-in-30) samples collected within a 30-day period. The WQG-ALs were applied in the following order:

- Use the most current BC approved WQG-AL (BC WLRS 2025a) or approved SBEBs (BC ENV 2023a).
- If no approved WQG-AL are available, use the most current Working Water Quality Guideline for BC (BC WLRS 2025b).
- If neither of these has yet been established, use the most current WQG-AL provided by CCME (2024a).

If a WQG-AL was dependent on toxicity modifying factors (e.g., pH-, hardness-, dissolved organic carbon- (DOC-), chloride-, etc.), mean concentrations for the group (month or 5-in-30) were used to calculate the WQG-AL. Long-term average (“chronic”) WQG-AL were used for initial comparisons. Long-term WQG-AL are the most conservative; consequently, if no exceedances of long-term guidelines are identified for a parameter, no further investigation is necessary. If exceedances of the chronic WQG-AL are noted, concentrations were also compared to the short-term (“maximum”) WQG-AL, where available.

Site-specific calculated dissolved aluminum SBEBs for stations on Davidson Creek (DC-05, DC-10, DC-15, and DC-20) were approved in March 2023 for use in the AEMP (BC ENV 2023a; Table 2.2-3). Comparisons to the SBEBs were done for the mean concentrations for the group (month or 5-in-30).

TABLE 2.2-2 WATER QUALITY GUIDELINES AND STANDARDS FOR THE PROTECTION OF AQUATIC LIFE

Parameter	BC Water Quality Guidelines[1]	CCME Guideline for the Protection of Freshwater Aquatic Life[2]	Proposed Yinka Dene Water Law Water Quality Standard[3]
Physical Parameters and Dissolved Anions			
pH	6.5 to 9.0 pH units	6.5 to 9.0 pH units	DC-05: 6.5 to 9.0 pH units CC-15: 6.8 to 8.1 pH units
Total suspended solids	Change from background for 24-h period is 25 mg/L and 5 mg/L for 30-day period; if background is 25-100 mg/L then change from background of 10 mg/L; if background > 100 mg/L then change from background of 10%	In clear flow, maximum increase of 25 mg/L from background levels for short-term exposure (e.g., 24-h period). Maximum average increase of 5 mg/L from background levels for long-term exposure. In high flow, maximum increase of 25 mg/L from background levels between 25-250 mg/L. If background is ≥ 250 mg/L, then it should not increase more than 10% of background levels.	BC Water Quality Guideline
Turbidity	In clear water, change from background for 24-h period = 8 NTU and 30-day period = 2 NTU; if background is 8-50 NTU then change from background is 5 NTU; if background > 50 NTU then change from background of 10%	In clear flow, maximum increase of 8 NTUs from background for short-term; maximum mean increase of 2 NTUs from background for long-term. In high flow, if background 8-80 NTU, maximum increase of 8 NTUs from background; if background >80 NTUs, increase <10% of background.	BC Water Quality Guideline
Chloride	600 maximum; 150 for 30-day period	640 short-term; 120 long-term	DC-05: 120 mg/L CC-15: 60 mg/L
Fluoride	0.4 mg/L maximum, at hardness ≤ 10 mg/L $CaCO_3$ LC_{50} = -51.73 + 92.57 log10 (hardness) * 0.01 mg/L, at hardness > 10 mg/L	0.12 mg/L (interim guideline)	DC-05: 1 mg/L CC-15: 0.53 mg/L

Parameter	BC Water Quality Guidelines[1]	CCME Guideline for the Protection of Freshwater Aquatic Life[2]	Proposed Yinka Dene Water Law Water Quality Standard[3]
Physical Parameters and Dissolved Anions *(cont'd)*			
Sulphate	30-day mean is: 128 mg/L, at hardness (as $CaCO_3$) 0-30 mg/L; 218 mg/L, at hardness 31-75 mg/L; 309 mg/L, at hardness 76-180 mg/L 429 mg/L, at hardness 181-250 mg/L site-specific guidelines apply at hardness >250 mg/L	-	DC-05: 218 mg/L CC-15: 111 mg/L
Nutrients			
Ammonia-N	30-day mean is pH- and temperature-dependent (see Table 26C in BC WLRS 2025a); No more than 1 of 5 of the measured values can exceed 1.5 times the corresponding guideline	pH- and temperature-dependent (long-term)	DC-05: 1.83 mg/L CC-15: 0.84 mg/L
Nitrate-N	32.8 mg/L maximum; 3.0 mg/L for 30-day period	550 mg/L short-term; 13 mg/L long-term	DC-05: 3 mg/L CC-15: 1.5 mg/L
Nitrite-N	the maximum concentration is 0.06 mg/L and the 30-day mean is 0.02 mg/L, at chloride < 2 mg/L; the maximum concentration is 0.12 mg/L and the 30-day mean is 0.04 mg/, at chloride 2-4 mg/L the maximum concentration is 0.06 mg/L and the 30-day mean is 0.18 mg/L, at chloride 4- 6 mg/L; the maximum concentration is 0.24 mg/L and the 30-day mean is 0.08 mg/L, at chloride 6-8 mg/L; the maximum concentration is 0.30 mg/L and the 30-day mean is 0.10 mg/L, at chloride 8-10 mg/L; the maximum concentration is 0.60 mg/L and the 30-day mean is 0.20 mg/L, at chloride > 10 mg/L.	0.06 long-term	DC-05: 0.02 mg/L CC-15: 0.011 mg/L

TABLE 2.2-3 SITE-SPECIFIC CALCULATED DISSOLVED ALUMINUM SCIENCE-BASED ENVIRONMENTAL BENCHMARKS FOR DAVIDSON CREEK

Dates for Comparison[1]	DC-05 (Reach A)	DC-10 (Reach B)	DC-15 (Reach C)	DC-20 (Reach D)
April 1 to July 31	0.28 mg/L	0.26 mg/L	0.25 mg/L	0.23 mg/L
August 1 to December 31	0.13 mg/L	0.11 mg/L	0.090 mg/L	0.079 mg/L

Notes:
[1] Water quality samples collected between January 1 and March 31 are compared to the total aluminum water quality guideline indicated in Table 2.2-2.

Site-specific YDWL standards were proposed in 2023 using the guidance within the *Yinka Dene 'Uza'hné Surface Water Guide to Surface Water Quality Standards* for two sites DC-05 (in Davidson Creek) and CC-15 (in Chedakuz Creek; Table 2.2-2) (Nadleh Whut'en and Stellat'en 2016b; Artemis Gold 2023). The proposed standards were updated and approved in early 2026 for the Yinka Dene Monitoring Program and were not available at the time of finalizing this interpretive report. The approved standards will be presented in future AEMP interpretive reports. The YDWL standards were develop based on a water classification system developed by Nadleh Whut'en and Stellat'en that provides a systematic basis for classifying receiving waterbodies relative to their importance and sensitivity to disturbance (Nadleh Whut'en and Stellat'en 2016a). Each numerical water quality standard is developed using the procedures appropriate for the waterbody under consideration. For example, Class II (sensitive waters) have standards that allocate no more than 50% of the assimilative capacity of receiving waters (Nadleh Whut'en and Stellat'en 2016b).

The exceedance of the guideline (WQG-AL, SBEB, or YDWL water quality standard) was identified for each site (month and/or 5-in-30) and the magnitude (factor) of exceedance was calculated (i.e., by how much the guideline is exceeded, calculated from the mean of parameter concentration, from the subset of concentrations greater than the guideline divided by the guideline).

2.2.4.4 QUALITY ASSURANCE/QUALITY CONTROL

For each pair of QA/QC field duplicate water samples, the relative percent difference (RPD) was calculated, where:

$$RPD = 100\% \times \left(\frac{|replicate\ 1 - replicate\ 2|}{\frac{replicate\ 1 + replicate\ 2}{2}} \right)$$

The RPD between the field duplicates is a measure of the variability inherent in field sampling (environmental heterogeneity, sampler handling leading to contamination, potential laboratory errors). Water quality parameters where one or both values were less than five times the DL were not included in the RPD calculations because variability near the DL is considered too high (BC MWLAP 2013). The *British Columbia Field Sampling Manual Part A Quality Control and Quality Assurance* (BC MWLAP 2013) recommends that any field duplicates with RPD values exceeding 20% and 50% should be noted and data should be interpreted accordingly. The results of RPD

calculations were examined to detect patterns of high variation for multiple parameters within sample pairs, indicating possible contamination during field sampling.

Both field and water quality observations were examined for their expected range of values and/or previous results. Detected concentrations of water quality parameters (concentrations above the DL) were noted for both travel and field blanks to indicate possible contamination. Based on statistical metrics and professional judgement, outliers indicating an error were removed. A combination of statistical metrics and/or criteria were used to identify potential outliers (e.g., data points outside of the 99th percentile) along with graphical analysis (Gilbert 1987). Professional judgement was also used to determine whether the data are likely to be outliers due to sampling or analysis issues (e.g., unit errors in laboratory report, sample contamination), or whether the data represent the true extreme of natural or expected conditions (e.g., very high concentrations of TSS and metals that may occur during a natural 1 in 100 storm event).

2.3 RESULTS AND DISCUSSION

Analytical and field in-situ measured results for the water quality are provided in Appendix A-1 and A-2 for streams and A-3 and A-4 for lakes. An assessment of the QA/QC results, including calculated RPDs of the field duplicate samples and outlier data removed from the data analysis, are provided in Appendix A-5. A characterization of the 2025 stream surface water quality is provided in Appendix A-6 with differences between the baseline, construction, and operations sampling periods summarized. Tatelkuz Lake and Kuyakuz Lake field and laboratory water quality are also summarized in Appendix A-6.

To support the evaluation of effects, timeseries graphs (2016 to 2025) are provided for the:

- laboratory parameters (Table 2.2-1) at each of the monitored stream sites (Appendix A-7); water quality guidelines, and SBEBs are indicated for applicable parameters;
- field parameters (Table 2.2-1) at each of the monitored stream sites (Appendix A-8);
- laboratory parameters (Table 2.2-1) at each of the monitored lake sites (Appendix A-9)— water quality guidelines are indicated for applicable parameters; and
- lake site field parameter profiles (Appendix A-10).

In 2025, all surface water quality samples and field measurements were collected by BW Gold in accordance with the AEMP Plan except for:

- One monthly sampling event (February) at TC-01 due to stagnant water present (February 24).
- One quarterly sampling event at TC-15 because the site was frozen to ground in February and March (February 3 and March 19);
- Two monthly sampling events (February and March) at 661-01 because the site was frozen to ground (February 3 and March 18);
- Two monthly sampling events (February and March) at 661-03 because the site was frozen to ground (February 18 and March 10); and
- One quarterly sampling event at TC-15 on July 7 because the location was dry.
- One monthly sampling event (August 11) at 661-03 due to the presence of stagnant water.

- One 5-in-30 sampling event at 661-10 on October 7 because of safety concerns related to Danger Trees in the area.
- One quarterly sampling event at TC-15 on November 26 because the location was dry.
- Two monthly sampling events at 661-03 because the stream was dry on October 7 and because the stream was frozen on December 12.
- On occasion, field measurements were not collected (e.g., dissolved oxygen, field pH, conductivity, and turbidity) because of probe issues, lack of a turbidimeter, or operator error.

Hydrology can be an important driver of stream water quality, as snowmelt or storm runoff can transport sediment into surface water bodies. High rainfall or snowmelt can also result in dilution, decreasing concentrations of dissolved solids. The 2025 stream hydrology is detailed in KP (2026a) and briefly summarized below. Stream water quality is also linked to stream flows, where relevant, in the following sections.

Base flows in the Mine site area are typically characterized by high spring flows driven by snowmelt (freshet), low summer and fall flows sustained by groundwater inflows and periodic rainfall events, and very low winter flows due to cold temperatures and freezing conditions (KP 2026a). In 2025, streamflow records were generally characterized by a unimodal hydrograph shape, with one distinct freshet peak in late May (and into early June at some stations), followed by recession to summer baseflows—this pattern is consistent with long-term site trends, where additional summer and/or fall peaks may occur during unusually wet years (KP 2026a). The streamflow records also indicate that stations with higher elevations and smaller catchments tend to experience relatively higher unit runoff during the spring freshet period and lower unit runoff during the summer, while stations directly downstream of a lake show runoff attenuation (flatter hydrographs) related to the storage capacity of the upstream lake (KP 2026a). Additionally, 2025 discharge records in the Davidson Creek watershed (DC-05 and DC-15) show short-duration flow fluctuations associated with mine water management/pumping activities. Heavy precipitation events typically lead to increased runoff into creeks – the largest prolonged rainfall event recorded in 2025 was recorded in August.

2.3.1 STUDY QUESTION 1—COMPARISON TO BASELINE

To answer the first study question (*Are AEMP component assessment endpoints at impact sites changing from baseline conditions or reference ranges as a result of the Mine?*), field measurements and water quality values/concentrations during construction and operations (October 2022 to December 2025) were compared to baseline (2016 to September 30, 2022).

Monitored stream field measurements typically fell within their baseline conditions or reference ranges for pH, temperature, conductivity, and dissolved oxygen (Appendix A-8). On occasion, field measurements were observed to deviate from this range, however, these deviations were not consistent and likely due to the inherent high natural variability in freshwaters.

The 2025 lake water quality (including field parameters) was visually compared with baseline measures and summarized in Appendix A-6. There were no changes in water quality at either of the monitored lakes suggesting no Mine-related effects.

A BACI analysis was completed for sites and water quality parameters to determine if there were Mine-related effects on surface water quality at potential impact sites downstream of the operations activities. The BACI analyses were completed for the Davidson Creek, Creek 661, and Chedakuz Creek watershed sites to assess the potential effects of the Mine-related activities in Year 1 of Operations (activities are summarized in Section 1.5; there were no PE-110652 authorized surface water discharges to Davidson Creek in 2025). Turtle Creek sites are located in the watershed where the Mine airstrip would be located. Therefore, the BACI analysis was not completed for Turtle Creek sites because the airstrip has not been constructed. The BACI analyses was completed for the water quality parameters that were greater than the baseline period [2016 to September 2022] (i.e., 95th percentile plus 20%) during the construction and operation activities in two or more consecutive months (i.e., not indicative of a spurious observation). The comparison of the construction and operations (i.e., October 2022 and onwards) monthly means to the 95th percentile baseline concentration plus 20% for the Davidson Creek, Creek 661, and Chedakuz Creek watershed sites DC-05, DC-10, DC-15, DC-20, 661-05, 661-10, 661-20, CC-15, CC-20, CC-30, and CC-40 are provided in Appendix A-11.

Water quality parameters selected for BACI analysis for each of the watersheds were:

- Davidson Creek—TSS, turbidity, chloride, sulphate, ammonia-N, nitrate-N, nitrite-N, total phosphorus, total aluminum, antimony, arsenic, barium, cadmium, chromium, cobalt, copper, iron, lead, lithium, manganese, mercury, molybdenum, nickel, silver, strontium, thallium, uranium, vanadium, and zinc; and dissolved aluminum, cadmium, iron, manganese and zinc. Dissolved cobalt was also included in response to the Level 3 trigger concentrations established in the Draft Groundwater Trigger Response Plan for Non-Point Source Discharges to Ground.
- Creek 661—pH, TSS, turbidity, TDS, chloride, sulphate, ammonia-N, nitrate-N, total phosphorus, ortho-phosphorus, total aluminum, antimony, arsenic, barium, beryllium, cadmium, chromium, cobalt, copper, iron, lead, manganese, molybdenum, nickel, selenium, silver, strontium, uranium, vanadium, and zinc; and dissolved aluminum, cadmium, iron, copper, manganese, and zinc.
- Chedakuz Creek—pH, turbidity, chloride, sulphate, ammonia-N, nitrate-N, total aluminum, arsenic, cadmium, cobalt, iron, lead, manganese, nickel, and uranium; and dissolved iron, manganese and zinc.

However, because 70% of the observations were less than the analytical detection limit, the BACI analyses were not completed for some parameters (Appendix A-12).

Davidson Creek

In lieu of the BACI analyses (that could not be completed), graphical analysis (i.e., a visual assessment) of the plots provided in Appendix A-7 indicated that the greater concentrations in 2025 at Davidson Creek sites when compared to baseline (that was not observed at regional control sites) were likely associated with construction activities, the 2023 wildfire, and/or 2025 Mine activities. The parameters with 2025 concentrations greater than baseline at one or more sites (based on graphical analysis) and the activity likely related to the increase are described below.

- *The 2023 wildfire, March 2025 TSS laden water release, and May and June 2025 clearing activities*

  TSS (Figure A7-5), chloride (Figure A7-9), total ammonia-N (Figure A7-12), nitrate-N (Figure A7-13), nitrite-N (Figure A7-14), total antimony (Figure A7-23), total and dissolved cadmium (Figure A7-28 and Figure A7-52), total chromium (Figure A7-29), total and dissolved lead (Figure A7-33 and Figure A7-57), total mercury (Figure A7-36), total vanadium (Figure A7-44), and total and dissolved zinc (Figure A7-45 and Figure A7-69) increases in 2025 are likely related to the water in the WMP that was conveyed intermittently throughout 2025 to the former Davidson Creek upstream of the future FWR. Water conveyed from the WMP was collected from the from the non-contact water diversions of overland flow from the 2023 fire-impacted upper Davidson Creek watershed via the CDS and the Creek 688 watershed. The March 2025 release of TSS laden water into Davidson Creek also likely contributed to elevated TSS, turbidity, nitrogen species, and total metals in Q1 2025 when compared to baseline. The tree clearing that was completed upstream of Davidson Creek in May/June 2025 also likely contributed to elevated TSS, turbidity, and total metals in Q2 and Q3 2025 when compared to baseline. The 2025 discharge records in Davidson Creek indicated short-duration flow fluctuations associated with the Mine water management/pumping activities and the largest prolonged rainfall event recorded in August 2025 (KP 2026a). The fluctuations and precipitation events typically lead to increased runoff of TSS laden water and associated total metals (e.g., total aluminum). Other 2025 high rainfall events recorded at the Mine meteorology stations occurred during the period of May 17 and 18, and July 30. The site also experienced warmer (above 0°C) in December 2025 (KP 2026a). Thus, elevated metal concentrations in Q3 and Q4 when compared to baseline (e.g., total zinc) may be related to rainfall events and warmer temperatures in December contributing to a snowmelt.

- *Unrecovered seepage from TSF C in Q3 and Q4 2025*

  Total ammonia-N (Figure A7-12), nitrate-N (Figure A7-13), nitrite-N (Figure A7-14), total and dissolved cobalt (Figure A7-30 and Figure A7-54), total and dissolved copper (Figure A7-31 and Figure A7-55a), and total and dissolved silver (Figure A7-40 and Figure A7-64) concentrations were greater (or were detectable) when compared to the Q3 and Q4 baseline concentrations at DC-05 and DC-10. Concentrations at DC-15 and DC-20 for some metals (i.e., total and dissolved cobalt) were also greater in Q3 and Q4 2025 when compared to baseline however the level of change was not as large when compared to DC-05. The Q4 groundwater concentrations in monitored groundwater wells downstream of the TSF C were greater than predicted (Year 1 TSF Seepage Predictions) for sulphate, nitrogen species, dissolved cobalt, chromium, nickel, silver, copper, and WAD cyanide (KP 2026b). Thus, greater concentrations of those parameters in surface water when compared to baseline indicate that they are likely associated with unrecovered seepage from TSF C.

- *2024 Construction Activities*

  Total thallium (Figure A7-42) concentrations were typically lower when compared to 2024 and similar to baseline suggesting no Mine-related effects in 2025.

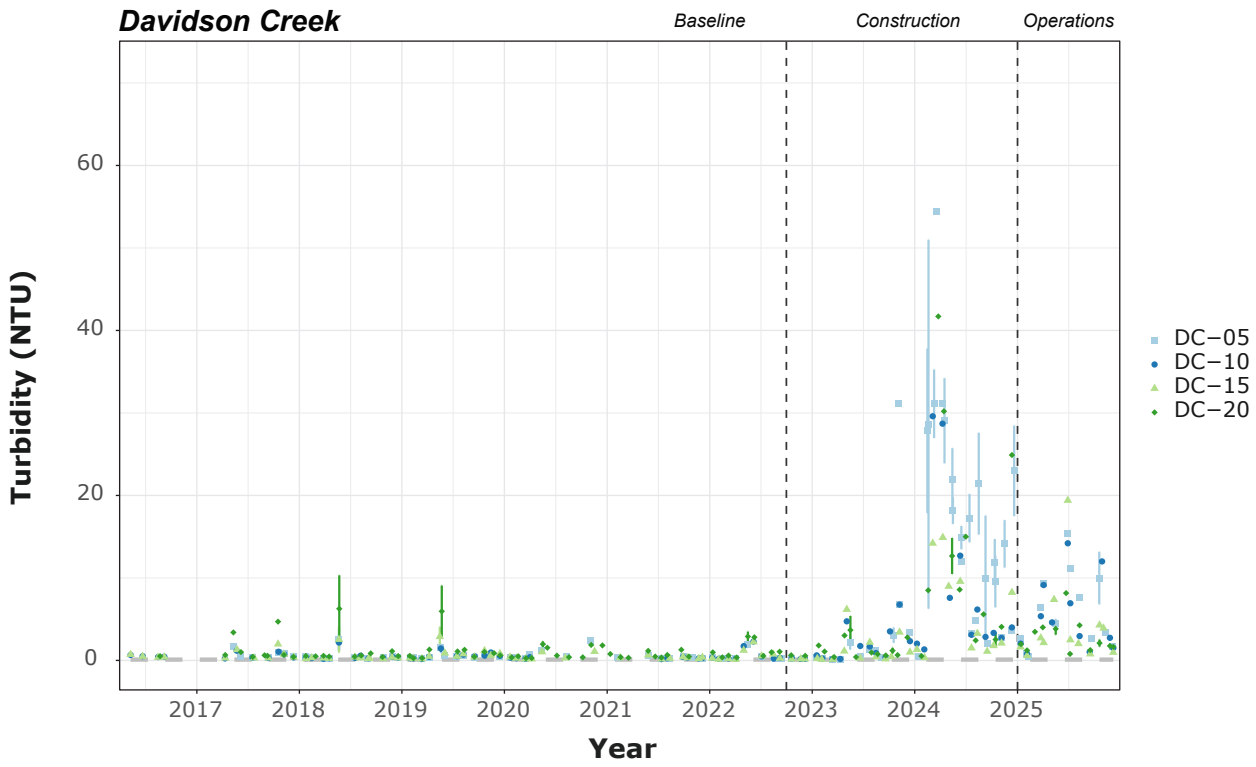
Results of the BACI analysis are provided in Appendix A-12 and summarized below. Water quality parameters with a significant ($p < 0.05$) "class" (control versus impact) and "period" (before versus after) interaction indicated that changes in the parameter concentrations at monitored impact sites before and after September 2022 were significantly different from the change at the control sites. Davidson Creek water quality parameters with a significant "class:period" interaction indicating that increases are likely related to Mine activities (during construction and/or Year 1 of operations) were turbidity, sulphate, total phosphorus, total aluminum, total arsenic, total barium, total and dissolved iron, total manganese, total molybdenum, total strontium, total uranium (Appendix A-12). For all other Davidson Creek water quality parameters, the BACI analysis results indicated a non-significant "class:period" interaction; therefore, changes were observed at both control and impact sites and is likely a natural phenomenon or unrelated to the Mine activities. (Appendix A-12).

Water quality parameters with significant "class:period" interactions observed for Davidson Creek sites were plotted to show monthly mean concentrations through baseline years (2016 to September 2022), construction Year 1 (October 2022 to 2023), construction Year 2 (2024) and operations (2025; Figures 2.3-1 to Figure 2.3-22), and discussed below:

- Turbidity (Figure 2.3-1 and Figure 2.3-2), total phosphorus (Figure 2.3-5 and Figure 2.3-6), and total aluminum (Figure 2.3-7 and Figure 2.3-8)—The Q1 to Q3 2025 turbidity, total phosphorus, and total aluminum monthly mean concentrations were greater than concentrations observed during the baseline period at Davidson Creek sites. Differences between the baseline concentrations and the 2025 concentrations beginning in Q1 and Q2 was likely associated with the non-contact water diversions of overland flow from the 2023 fire-impacted upper Davidson Creek watershed via the CDS to the WMP (and conveyed intermittently throughout 2025 to the former Davidson Creek upstream of the future FWR). The March 2025 release of TSS laden water into Davidson Creek also likely contributed to elevated concentrations in Q1 2025 when compared to baseline. The tree clearing that was completed upstream of Davidson Creek in May/June 2025 also likely contributed to elevated concentrations in Q2 and Q3 2025 when compared to baseline. Increases in turbidity and TSS associated total phosphorus and aluminum are also related to the short-duration flow fluctuations associated with the Mine water management/pumping activities and the largest prolonged rainfall event recorded in August 2025 (KP 2026a). Other 2025 high rainfall events recorded at the Mine meteorology stations occurred during the period of May 17-18, and July 30 corresponding to increases in TSS. There was also a decreasing trend with downstream distance supporting the conclusion the increases are related to the 2025 Mine activities. However, the 2025 monthly concentrations were typically lower when compared to 2024 indicating the statistically significant result is largely related to activities occurring in 2024 (i.e., the TSFC-SCP discharge).
- Total barium (Figure 2.3-11 and Figure 2.3-12)—The 2025 total barium concentrations at Davidson Creek sites were generally lower when compared to 2024 concentrations but greater than baseline. This trend suggests the statistically significant effect is largely attributed to the 2024 activities (i.e., initiation of discharge from TSFC-SCP to Davidson Creek). Similar trends were observed in 2023, and there is no consistent trend of increases with downstream distance therefore the greater total barium concentrations are attributed to construction activities and not discharges to Davidson Creek.

- Sulphate (Figure 2.3-3 and Figure 2.3-4)—The 2025 sulphate mean concentrations observed in Q3 and Q4 were greater than concentrations observed during the baseline period at Davidson Creek sites DC-05 and DC-10. At regional control sites, sulphate was generally similar among monitored years in both the before and after periods. The statistically significant difference is likely associated with TSF C seepage because the increase occurred later in 2025 and the elevated total concentrations were predominantly in the dissolved form (i.e., associated with groundwater seepage).
- Total arsenic (Figure 2.3-9 and Figure 2.3-10)—The Q3 mean monthly total and dissolved arsenic concentrations were greater than baseline and are potentially related to the 2025 construction activities (i.e., similar increases in concentrations were observed in 2023 and 2024 although not as large). As observed during the 2023 and 2024 construction period, total and dissolved arsenic concentration in Q4 2025 were similar to baseline concentrations. Thus, any Mine-related effects were limited to Q3 2025.
- Total uranium (Figure 2.3-21 and Figure 2.3-22)—The Q1 to Q3 2025 mean monthly total uranium concentrations were greater than baseline and can be attributed to the 2023 wildfire, the TSS laden water release in March 2025 and the tree clearing completed upstream of Davidson Creek in May/June 2025. Greater dissolved uranium in Q3 and Q4 2025 when compared to baseline may be potentially related to groundwater. However, groundwater well concentrations downstream of the TSF C did not have elevated uranium concentrations (KP 2026b).
- Total and dissolved iron (Figure 2.3-13 and Figure 2.3-14)—The 2025 total and dissolved iron at Davidson Creek sites were generally lower when compared to 2024 concentrations and similar to baseline. This trend suggests the statistically significant effect is largely attributed to the 2024 activities (i.e., initiation of discharge from TSFC-SCP to Davidson Creek). The significance also had relatively low power (8%) attributed to the variability through all monitoring years (Appendix A-12). Greater total and dissolved iron concentrations were observed at DC-20 when compared to upstream sites indicating that the 2025 concentrations at DC-20 is not entirely related to construction activities (a similar conclusion was made in 2024 with iron concentrations associated with cattle grazing occurring adjacent to the site).
- Total and dissolved manganese (Figure 2.3-15 and Figure 2.3-16)—The Q3 and Q4 2025 mean monthly total manganese concentrations were greater than baseline and can be attributed to the tree clearing that was completed upstream of Davidson Creek in May/June 2025 and the discharge from the WMP. The 2025 discharge records in Davidson Creek indicated short-duration flow fluctuations associated with the Mine water management/pumping activities and the largest prolonged rainfall event recorded in August 2025 (KP 2026a). The fluctuations and precipitation events typically lead to increased runoff of TSS laden water and associated total metals. Other 2025 high rainfall events recorded at the Mine meteorology stations occurred during the period of May 17 and 18, and July 30. The site also experienced warmer (above 0°C) in December 2025 (KP 2026a). Thus, elevated manganese concentrations in Q3 and Q4 when compared to baseline may be related to rainfall events and warmer temperatures in December contributing to a snowmelt. In addition, the greater total and dissolved manganese concentrations at DC-20 when compared to upstream sites and baseline concentrations are indicative of anthropogenic sources that may contribute to DC-20 water quality (e.g., cattle grazing) based on the adjacent cattle ranch and not mine impact related.

FIGURE 2.3-1 MONTHLY MEAN TURBIDITY CONCENTRATIONS AT DAVIDSON CREEK SITES, BASELINE (2016 TO SEPTEMBER 2022), CONSTRUCTION (OCTOBER 2022 TO 2024), OPERATIONS (2025) MONITORING PERIODS



Notes: Error bars represent standard error of the mean.

BC WQG–AL working long–term guideline for total uranium is 0.0085 mg/L.

- Total molybdenum (Figure 2.3-17 and Figure 2.3-18)—The 2025 total molybdenum at Davidson Creek sites were generally lower when compared to 2024 concentrations and similar to baseline. This trend suggests the statistically significant effect is largely attributed to the 2024 activities (i.e., initiation of discharge from TSFC-SCP to Davidson Creek).
- Total strontium (Figure 2.3-19 and Figure 2.3-20)—There was an increase in total strontium concentrations at Davidson Creek sites beginning in construction when compared to the baseline period that was not observed at the regional control sites. The elevated total strontium at the Davidson Creek sites were restricted to sites further downstream (i.e., DC-20), therefore not attributed to 2025 Mine Activities.

Creek 661

Although BACI analyses could not be completed, graphical analysis indicates that there was a greater proportion of detectable concentrations and/or greater concentrations observed in 2025 when compared to baseline years for the following parameters:

- TSS (661-03, 661-10; Figure A7-5)
- Chloride (661-04, 661-05, 661-10; Figure A7-9)
- Total ammonia-N (661-10; Figure A7-12)
- Total nitrate-N (661-04, 661-10; Figure A7-13)
- Total antimony (661-04, 661-05, 661-10; Figure A7-23)
- Total beryllium (661-04, 661-05, 661-10; Figure A7-26)
- Total cadmium (661-04, 661-05, 661-10; Figure A7-28)
- Total chromium (661-04, 661-05, 661-10; Figure A7-29)
- Total cobalt (661-04, 661-05, 661-10; Figure A7-30)
- Total copper (661-04, 661-05, 661-10; Figure A7-31)
- Total lead (661-04, 661-05, 661-10; Figure A7-33)
- Total nickel (661-05; Figure A7-38)
- Total selenium (661-05; Figure A7-39)
- Total silver (661-05; Figure A7-40)
- Total vanadium (661-04, 661-05; Figure A7-44)
- Total zinc (661-04, 661-05; Figure A7-69)
- Dissolved cadmium (661-04, 661-10; Figure A7-52)
- Dissolved zinc (661-04, 661-05, 661-10; Figure A7-56)

Greater concentrations were typically observed in 2024 (and to some extent 2023) when compared to 2025 and baseline years at near-field sites thus increases could be related to construction related activities (including the discharge to ground from the PS-SCP; KP 2025). However, it is also likely that 2025 construction activities were attributed to the greater concentrations in 2025 when compared to baseline.

The 2023 and 2024 wildfires occurred in areas of upstream of Creek 661 and in the immediate vicinity of site 661-20 (Figure 1.4-1). Thus, changes in water quality are also likely related to the wildfires when it cannot be confirmed they were related to construction or 2025 Mine activities. This includes the observed increase in total phosphorus, TDS, and chloride post-wildfire likely as a result of the deposition of ash (Water Research Foundation 2013; BC Health 2024). In addition, greater concentrations of TSS and total metals (i.e., total aluminum, total arsenic, total copper, total nickel, total silver) beginning with the 2025 snowmelt in late March and freshet conditions may be directly related to the 2023 and 2024 fire-impacted Creek 661.

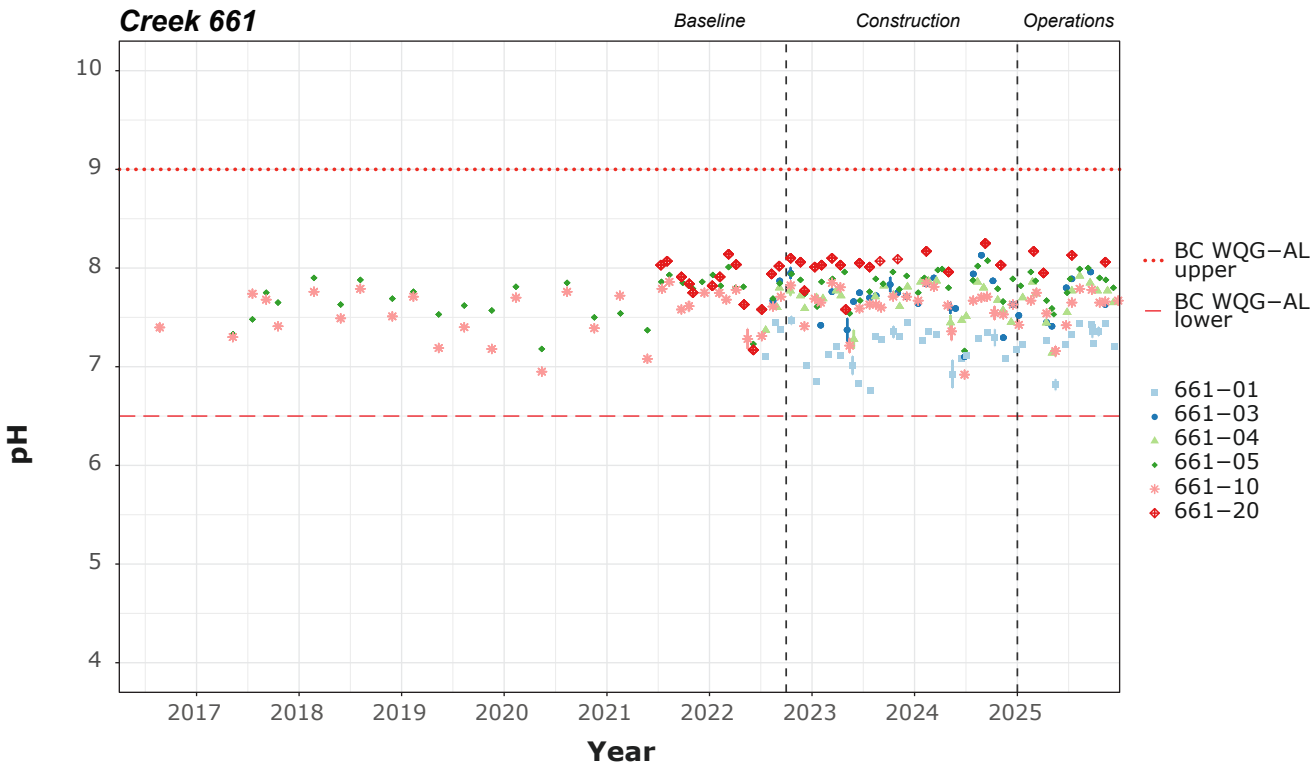
Surface water quality monitoring data obtained at site 661-04 at tributary Creek 146920 and 661-05 at tributary Creek 505659 and the downstream site 661-10 was also reviewed to investigate if ore stockpile dust event that occurred in Q1 2025 affected metal concentrations in surface water in Creek 661. Comparison of the May 2025 to the May 2024 water quality at sites 661-04, 661-05 indicated that some metals (total and dissolved cadmium, total and dissolved copper, and total and dissolved zinc) were elevated as a result of the dust event (Figures A7-28, A7-52, A7-31, A7-55, A7-45, A7-69; Lorax 2025). There was no or minimal impact of the dust event on site 661-10 water quality in May 2025 and concentrations at 661-04 and 661-05 were at concentrations that were not expected to have long-term effects to aquatic life (Lorax 2025). However, sediments and benthic invertebrate community and tissue monitoring were completed in early September 2025 at 661-04 (immediately downstream of the dust event) to assess if effects were observed (see Section 4.4 and Section 6.4).

Significant "class:period" BACI analysis results were detected for turbidity (Figure 2.3-25 and Figure 2.3-2), total aluminum (Figure 2.3-29 and Figure 2.3-8), arsenic (Figure 2.3-30 and Figure 2.3-10), and barium (Figure 2.3-31 and Figure 2.3-12). For all parameters, concentrations in Q3 and Q4 2025 were similar to baseline years indicating the influence from the 2023 and 2024 wildfires upstream of Creek 661 sites in addition to 2025 construction activities and not likely to affect aquatic life during the highest period of productivity in late August/early September.

Other water quality parameters with significant "class:period" interactions observed for Creek 661 sites were plotted to show monthly mean concentrations through baseline years (2016 to September 2022), construction Year 1 (October 2022 to 2023), construction Year 2 (2024) and operations (2025) are discussed below:

- pH (Figure 2.3-23 and Figure 2.3-24)—The pH observed during construction and 2025 were greater than or similar to concentrations observed during the baseline period at all Creek 661 sites. At the regional control sites, pH was variable in both the before and after periods. Graphical analysis indicates no temporal or spatial trends therefore the statistically significant increase is not considered to be a Mine-related effect.
- TDS (Figure 2.3-26 and Figure 2.3-27)—Total dissolved solids concentration was elevated in Q1 2025, suggesting that there may be impacts on surface water from dissolved parameters, potentially from groundwater discharging to Creek 661 and its tributaries. However, with the exception of nitrate, the Q1 2025 measured concentrations of parameters in groundwater, including TDS, downgradient of the plant site tended to be similar to or lower than previous monitoring results (the number of samples and monitoring years differed among monitoring wells; KP 2026b). Thus, it cannot be confirmed the increase in TDS is a Mine-related effect.

FIGURE 2.3-23 MONTHLY MEAN PH (LABORATORY) AT CREEK 661 SITES, BASELINE (2016 TO SEPTEMBER 2022), CONS TRUCTION (OCTOBER 2022 TO 2024), OPERATIONS (2025) MONITORING PERIODS



Notes: Error bars represent standard error of the mean.
BC WQG–AL upper limit is 9.0 pH units and lower limit is 6.5 pH units.

Gray dashed line indicates minimum detection limit.
Concentrations below the detection limit were plotted as half the detection limit.
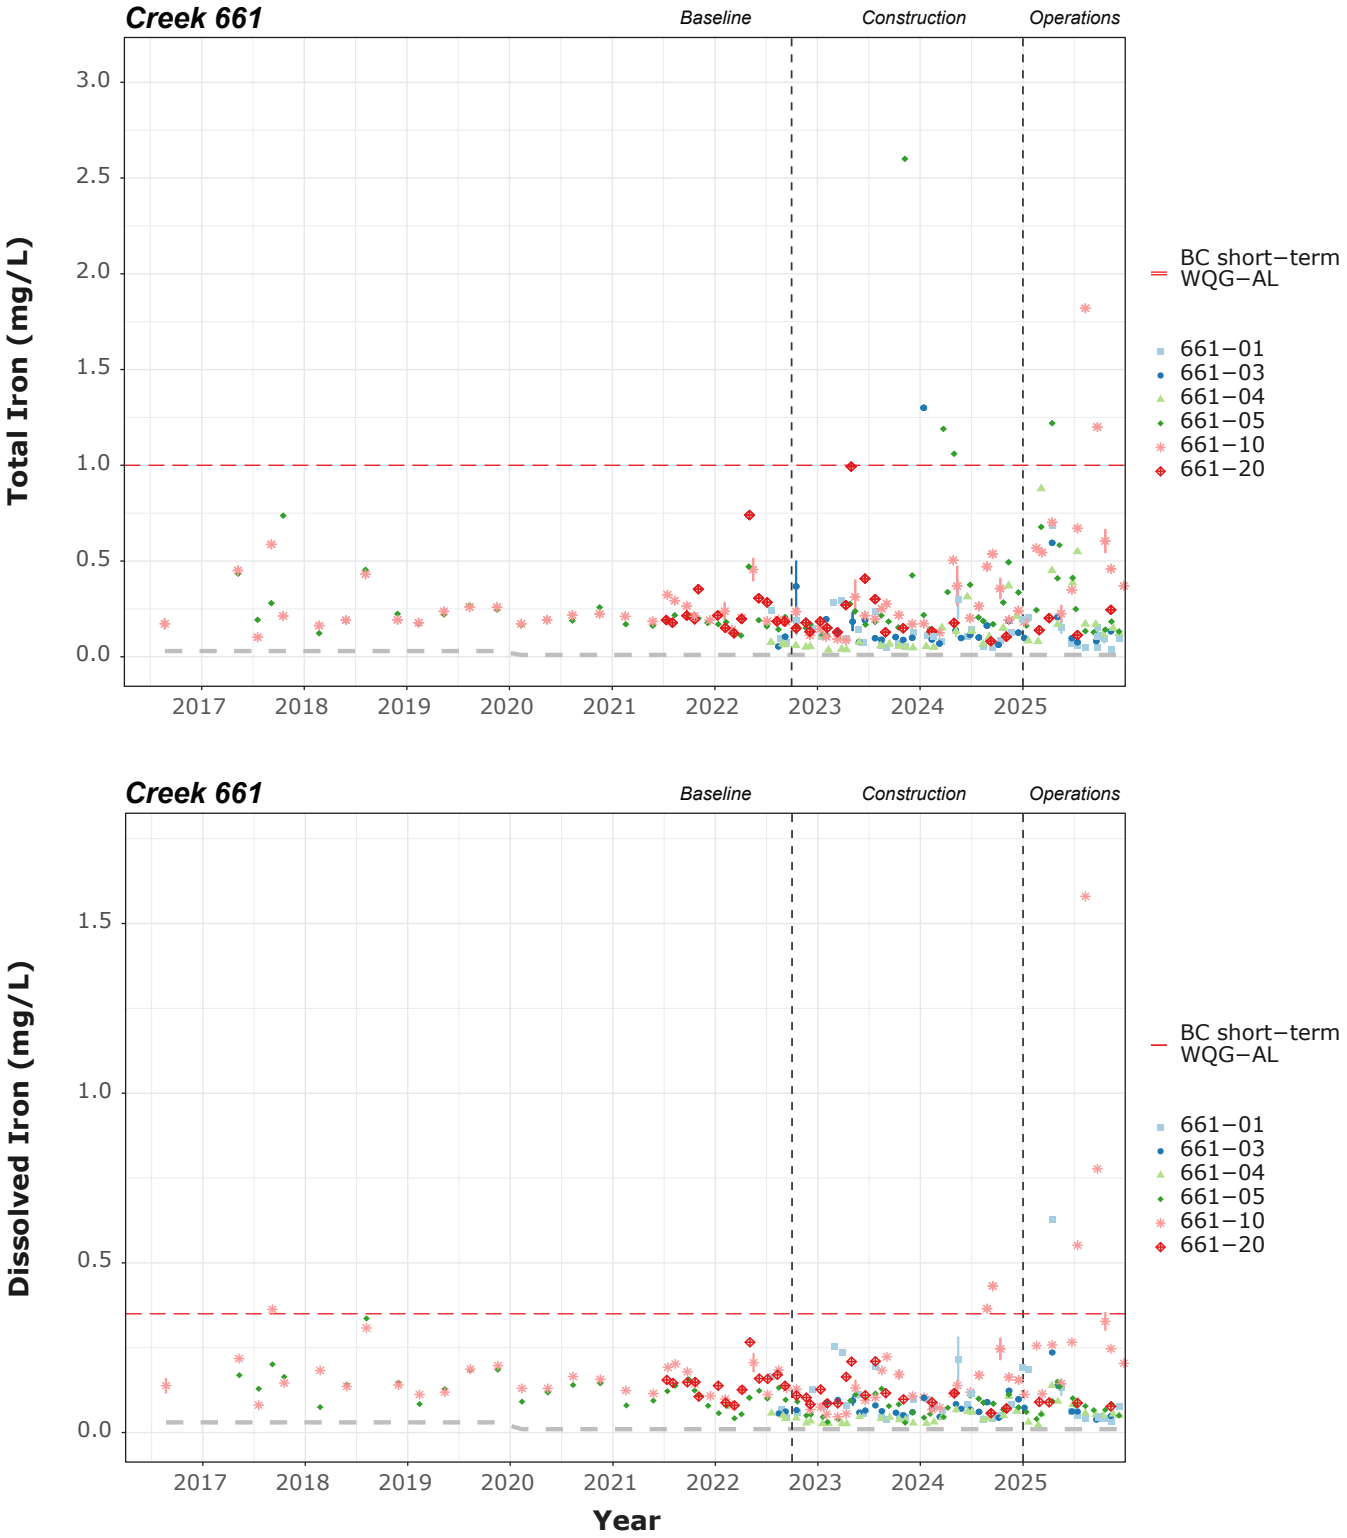
BC WQG–AL working long–term guideline for total uranium is 0.0085 mg/L.
BC WQG–AL long–term guideline for dissolved uranium is 0.0075 mg/L.

FIGURE 2.3-34 MONTHLY MEAN IRON CONCENTRATIONS AT CREEK 661 SITES, BASELINE (2016 TO SEPTEMBER 2022), CONSTRUCTION (OCTOBER 2022 TO 2024), OPERATIONS (2025) MONITORING PERIODS



Notes: Error bars represent standard error of the mean.
Gray dashed line indicates minimum detection limit.
Concentrations below the detection limit were plotted as half the detection limit.
BC WQG−AL short−term maximum guideline for total iron is 1.0 mg/L.
BC WQG−AL short−term guideline for dissolved iron is 0.35 mg/L.

- Total phosphorus (Figure 2.3-28 and Figure 2.3-6)—Total phosphorus concentrations at Creek 661 sites were greater in construction and operations when compared to the baseline period. At the regional control sites and the upstream control site (661-01), total phosphorus was variable (similar or greater) in both the before and after periods. The increase in total phosphorus concentrations at 661-05 and 661-10 coincide with the initiation of construction and Q1 2025 Mine activities and concentrations tend to decrease with downstream distance to site 661-20 in most months. Thus, statistical and graphical analysis indicate the increase in total phosphorus in Q1 is likely a Mine-related effect (construction activities) and associated with the 2023 and 2024 wildfires. However, the sporadic elevated concentrations observed at 661-10 in August and September 2025 are not likely related to the Mine activities (i.e., not observed at upstream 661-04, 661-03, and 661-05 sites).
- Total strontium (Figure 2.3-32 and Figure 2.3-20) and total uranium (Figure 2.3-33 and Figure 2.3-22)—There was an increase in total strontium and uranium concentrations at all Creek 661 impact sites during construction and operation periods when compared to the baseline period that was not observed at 661-01 and the regional control sites. Based on graphical analysis the greatest elevated total strontium and uranium concentrations were restricted to site 661-20 (and not the near-field sites) and in all months when compared to the monthly concentrations observed during baseline years. Therefore, the statistically significant increase at 661-04, 661-05 and 661-10 is likely associated with 2024 and 2025 construction activities. The greater total strontium and uranium concentrations at site 661-20 in 2025 is not related to Mine activities and may be associated with effects of the 2024 wildfire that occurred in the vicinity of the site.
- Dissolved iron (Figure 2.3-34 and Figure 2.3-14)—The significant increase in dissolved iron is associated with the elevated dissolved iron concentrations observed at 661-10 in Q3 of 2025 that was also observed at the regional control sites and not observed at the upstream sites. Dissolved iron was similar between the baseline, construction, operations periods at all other impact sites, indicating there was no Mine-related effect.

Chedakuz Creek

Although BACI analyses could not be completed, graphical analysis indicates that there was a greater proportion of detectable concentrations and/or greater concentrations observed in 2025 for the following parameters:

- Chloride (CC-15, CC-20, CC-40; Figure A7-9)
- Nitrate-N (CC-15, CC-20, CC-40; Figure A7-13)
- Total cadmium (CC-15, CC-40; Figure A7-29)
- Total cobalt (CC-15, CC-20, CC-40; Figure A7-30)
- Total lead (CC-15, CC-20, CC-40; Figure A7-33)
- Total nickel (CC-15, CC-20, CC-40; Figure A7-38)
- Dissolved zinc (CC-15, CC-05; Figure A7-69)

The 2025 concentrations were generally lower than when compared to 2024 concentrations which were likely attributed to construction activities. However, there is no decreasing trend with downstream distance and changes cannot be entirely attributed to the Mine and instead attributed

to other anthropogenic sources that may contribute to Chedakuz Creek water quality (e.g., forest harvesting activities, road/trail networks, cattle grazing).

Water quality parameters with significant "class:period" interactions observed for Chedakuz Creek sites were detected for:

- pH (Figure 2.3-35 and Figure 2.3-24)—The monthly mean pH at CC-05 and CC-10 was greater in July 2025 when compared to baseline. The 2025 monthly mean pH at all other sites were generally similar to the construction period and baseline with exception of the upstream control site CC-03. Thus, changes in pH were not Mine-related at Chedakuz Creek sites.
- Turbidity (Figure 2.3-36 and Figure 2.3-2)—The 2025 and the monthly mean turbidity during the construction period were greater than levels observed during the baseline period at Chedakuz Creek sites downstream of the confluence with Davidson Creek CC-15, CC-20, CC-40. Similar trends were not observed at regional control sites or the upstream control (CC-03), CC-05, CC-10, and CC-30. Graphical analysis indicates the increase at sites CC-15 and CC-20 may be related to the 2025 Mine activities (i.e., effects observed in Davidson Creek may also extend to those sites downstream of the confluence) but not at CC-40 (i.e., no decreasing trend with downstream distance). The concentrations at DC-20 (upstream of the confluence with Chedakuz Creek) is not entirely related to construction activities and there are several anthropogenic sources that may contribute to Chedakuz Creek water quality (e.g., forest harvesting activities, road/trail networks, cattle grazing). Therefore, increased turbidity at CC-15, CC-20, CC-40 are not entirely related to construction activities.
- Sulphate (Figure 2.3-37 and Figure 2.3-4)—Monthly mean sulphate concentrations observed in 2025 were typically greater in Q1 and Q2 of 2025 at all Chedakuz Creek sites when compared to baseline. However, graphical analysis indicates the increases at sites CC-30 and CC-40 were greater when compared to regional control sites, the upstream control (CC-03), CC-05, CC-10, CC-15 and CC-20. Thus, the increases are not related to Mine-related sources.
- Total ammonia-N (Figure 2.3-38 and Figure 2.3-39)—Monthly mean total ammonia-N concentrations observed during construction months (October to December 2024) and Q1 and Q2 2025 were greater than concentrations observed during the baseline period at Chedakuz Creek sites CC-15, CC-20, CC-30, CC-40. Similar trends were not observed at regional control sites, the upstream control (CC-03), CC-05, CC-10. Graphical analysis indicates the increase at sites CC-15 and CC-20 may be related to Mine activities but not at CC-30, CC-40 (i.e., no decreasing trend with downstream distance).
- Total aluminum (Figure 2.3-40 and Figure 2.3-8), and total barium (Figure 2.3-41 and Figure 2.3-12)—Monthly mean total aluminum and barium concentrations observed during construction months (April to May and October to December 2024), and April to June 2025 were greater than concentrations observed during the baseline period at Chedakuz Creek sites CC-15, CC-20, CC-40. Similar trends were not observed at regional control sites, the upstream control (CC-03), CC-05, CC-10, or CC-30. Graphical analysis indicates the increase at sites CC-15 and CC-20 may be related to the Mine activities but not at CC-40 (i.e., no decreasing trend with downstream distance). In addition, total aluminum and barium concentrations beginning in July through to December 2025 were similar to baseline at all Chedakuz Creek sites indicating the statistical significance was largely associated with 2024 activities.

FIGURE 2.3-35 MONTHLY MEAN PH (LABORATORY) AT CHEDAKUZ CREEK SITES, BASELINE (2016 TO SEPTEMBER 2022), CONSTRUCTION (OCTOBER 2022 TO 2024), OPERATIONS (2025) MONITORING PERIODS

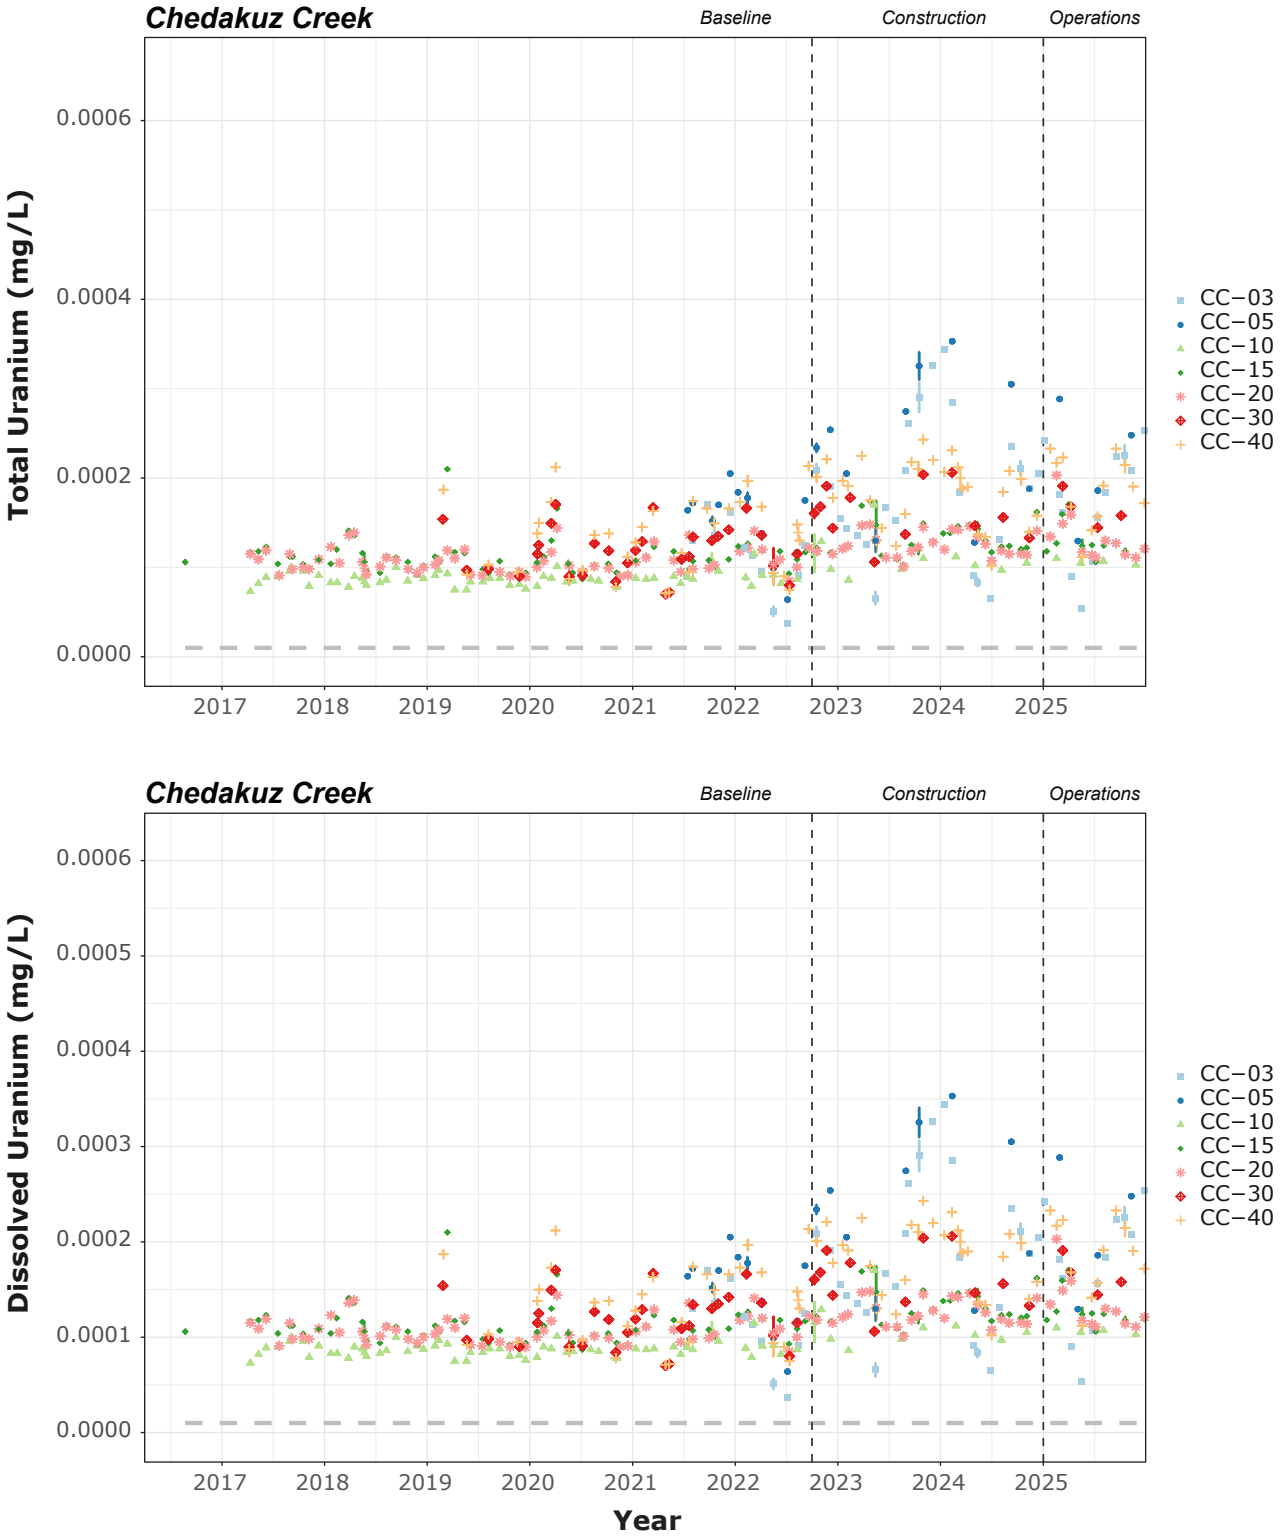
Proposed YDWL Standard for dissolved manganese at CC−15 is 0.019 mg/L.

FIGURE 2.3-44 MONTHLY MEAN URANIUM CONCENTRATIONS AT CHEDAKUZ CREEK SITES, BASELINE (2016 TO SEPTEMBER 2022), CONSTRUCTION (OCTOBER 2022 TO 2024), OPERATIONS (2025) MONITORING PERIODS



Notes: Error bars represent standard error of the mean.
Gray dashed line indicates minimum detection limit.
Concentrations below the detection limit were plotted as half the detection limit.
BC WQG–AL working long–term guideline for total uranium is 0.0085 mg/L.
BC WQG–AL long–term guideline for dissolved uranium is 0.0075 mg/L.

- Total iron (Figure 2.3-42 and Figure 2.3-14)—There was an increase in total iron concentrations at Chedakuz Creek sites from baseline to construction years and April to June 2025. The greatest difference between baseline and April to June 2025 were typically at CC-30 and CC-40 therefore increase is not Mine-related and likely related to several anthropogenic sources that may contribute to Chedakuz Creek water quality (e.g., forest harvesting activities, road/trail networks, cattle grazing).
- Total and dissolved manganese (Figure 2.3-43 and Figure 2.3-16)—Dissolved manganese concentrations at Chedakuz Creek sites CC-15, CC-20, CC-30, and CC-40 were greater during construction months and 2025 when compared to the baseline period. Similar trends were not observed at regional control sites, the upstream control (CC-03), CC-05, or CC-10. Graphical analysis indicates the increase at sites CC-15, CC-20, and CC-30 may be related to the 2024 construction activities but not at CC-40 (i.e., no decreasing trend with downstream distance). The greatest difference between baseline and April to June 2025 were typically at CC-30 and CC-40 therefore increase is not Mine-related and likely related to several anthropogenic sources that may contribute to Chedakuz Creek water quality (e.g., forest harvesting activities, road/trail networks, cattle grazing).
- Total uranium (Figure 2.3-44 and Figure 2.3-22)—There was an increase in total uranium concentrations at Chedakuz Creek sites from baseline to construction years. The greatest difference between baseline, construction months, and 2025 were at CC-03 (upstream control) and CC-05 therefore the increase at all sites is not likely related to Mine activities.

2.3.2 STUDY QUESTION 2—COMPARISON TO MODEL PREDICTIONS

To answer the second study question (*Are AEMP component assessment endpoints changing in ways that were not predicted by models or is mitigation less successful than anticipated?*) mean monthly surface water quality concentrations were compared to water quality model predictions (model v.13e; Lorax 2022).

Water quality predicted at assessment nodes was compared to the associated AEMP sampling site. The monthly predicted concentrations (95th percentile) at each of the assessment nodes and the AEMP sampling sites in Davidson Creek, Chedakuz Creek, and Creek 661 sites (i.e., sites potentially impacted by surface water discharge and construction activities) were compiled and provided in Appendix A-13.

Table 2.3-1 summarizes the parameters where the mean monthly concentration beginning in October 2022 to December 2025 were greater than its respective monthly maximum monthly base case predicted concentration (i.e., the model predicted 95th percentile) for two or more consecutive months.

The mean monthly concentrations during the construction period were greater than the model predictions for several water quality parameters at Davidson Creek, Chedakuz Creek, and Creek 661 sites (Table 2.3-1). As discussed in Section 2.3.1, greater concentrations than predicted are likely related to the 2024 construction activities (i.e., discharge from TSFC-SCP), the 2023 and 2024 wildfires, and 2025 Mine activities. The potential for Mine-related changes in water quality during construction phase are primarily through increases in TSS and particulate-bound metals due to

earthworks activities, which are not accounted for in source terms used in the mass-balance surface water quality model. The TSS and particulate-bound metals associated with the wildfires are also not accounted for in the model. Unrecovered seepage from TSF C (a 2025 Mine source) was predicted to enter Davidson Creek in Year 5 of operations, however the model seepage rate sensitivity scenarios highlighted that additional management, and mitigations may be required to mitigate the potential for WQG-AL exceedances (Lorax 2022). Future updates to the model, are expected to reflect changes in mitigation and management measures and changes in the Mine plan (i.e., delay in the FWR construction and discharge to the receiving environment).

TABLE 2.3-1 WATER QUALITY PARAMETERS GREATER THAN MODEL PREDICTIONS, OCTOBER 2022 TO DECEMBER 2025

Watershed	Water Quality Model (Lorax 2022)	Aquatic Effects Monitoring Program Sampling Site	Water Quality Parameters[1]
Davidson Creek	WQ28	DC-05	• Dissolved anion: chloride • Total metals: aluminum, arsenic, barium, copper, iron, lead, and uranium • Dissolved metals: aluminum
	WQ27	DC-10	• Dissolved anion: chloride • Total metals: aluminum, barium, copper, iron, lead, uranium, and zinc • Dissolved metals: aluminum
	WQ26	DC-15	• Dissolved anion: chloride • Total metals: aluminum, barium, copper, iron, lead, and uranium • Dissolved metals: aluminum

Notes:
[1] Mean monthly concentration in two or more consecutive months for the October 2022 to December 2025 period was greater than the model predicted 95th percentile.
* Indicates parameter was not observed to be greater than the predicted 95th percentile concentration at near-field sites and therefore are not likely attributed to Mine-related effects.

2.3.3 STUDY QUESTION 3—COMPARISON TO WATER QUALITY GUIDELINES, SCIENCE-BASED ENVIRONMENTAL BENCHMARKS, AND STANDARDS

To answer the third study question (*Are AEMP component assessment endpoints at impact sites changing to levels that may be associated with effects as a result of the Mine?*) stream and lake water quality in 2025 was compared to applicable WQG-ALs, SBEBs, and YDWL standards (BC WLRS 2025a, 2025b, 2023a; CCME 2025a).

Tables 2.3-2 to 2.3-5 provide summaries of the magnitude of exceedances observed in 2025 for monitored streams and lakes. For parameters that exceeded WQG-AL in 2025, a summary of the frequency and magnitude of exceedances observed in streams during baseline, construction, and operations for comparison is provided in Table 2.3-6. A comparison to the approved dissolved aluminum SBEBs at Davidson Creek sites (DC-05, DC-10, DC-15, and DC-20) are applicable for the months of April to December (Table 2.3-2). Water quality samples collected between January and March were compared to the total aluminum water quality guideline. A YDMP has been developed with a response framework specific to the YDWL standards that is expected to protect the water resources within the territories of the NFNs. The implementation of the YDMP Response Framework (including the assessment of exceedances of the YDWL standards) will be reported separately and not discussed further in this AEMP Interpretive Report. The exceedances of the proposed YDWL standards are summarised in Table 2.3-7.

The 2025 detection limits were less than or equal to the applicable WQG-AL, therefore there were no instances of exclusions from exceedance calculations.

Parameters above WQG-ALs were observed at Davidson Creek sites for total iron (April, June to December) and dissolved cobalt (August to December; Table 2.3-2). Exceedances of the dissolved zinc WQG-AL was observed at DC-05 (February) and DC-20 (February and March), a single instance of total cadmium above the WQG-AL occurred in June at DC-05. Dissolved iron concentrations were above the BC short-term WQG-AL guideline at DC-20 in June, August, September and November (Table 2.3-2). The magnitude of exceedance for total iron ranged from 1.19-times to 2.52-times greater than the WQG-AL. Dissolved cobalt exceedances occurred from August through December at all sites with magnitudes ranging from 1.18-times to 7.25-times greater than the WQG-AL. Short-term dissolved iron exceedances and dissolved zinc exceedances at DC-20 were of low magnitude (less than 3-times the WQG-AL). Except for dissolved cobalt, the magnitude of exceedance at Davidson Creek sites (i.e., less 3-times the WQG-AL) and no trends with downstream distance (e.g., exceedances observed only at DC-20) suggest the exceedance are not Mine related and no adverse effects to aquatic life are expected. The dissolved cobalt concentration at DC-10 in October 2025 was less than 2.5-times the WQG-AL guideline and was less than the September result (7.25-times the guideline), indicating that the September observation was likely a spurious event with no long-term effects to aquatic life expected. The consistent exceedances at all sites throughout the August to December monitoring period (and typically the greatest magnitude of exceedance at the near-field DC-05 and DC-10 sites) suggest concentrations reflect Mine-related sources. The magnitude of the exceedances at DC-05 and DC-10 in November and December (i.e., greater than four-times the guideline) if persistent, could have the potential for certain limited long-term effects to aquatic life. Dissolved cobalt will continue to be monitored in accordance with regulatory requirements. That said, BW Gold

implemented mitigation measures to capture Mine-related sources in late 2025 and early 2026 and is permitted to construct additional structures downstream of the present extent of Mine-related sources of water that are expected to provide further mitigation. BW Gold plans to commence construction of these structures in 2026. These mitigation measures are expected to positively impact water quality in future years.

A comparison to the approved dissolved aluminum SBEB at Davidson Creek sites indicated exceedances at DC-05 and DC-20 in May/June, and at DC-15 in June, with magnitudes ranging from 1.11 to 1.80 (Table 2.3-2). Total aluminum exceedances occurred at DC-05, DC-10, and DC-15 with magnitude range between 1.03 and 2.17 times the WQG-AL. The low frequency and magnitude of exceedances suggest no adverse effects to aquatic life are expected. The dissolved aluminum and dissolved manganese YDWL standard were exceeded at DC-05 (May to November). However, the magnitude of exceedance was low, ranging from 1.03 to 2.36-times the standard (Table 2.3-2).

Relative to baseline, exceedance frequencies and magnitudes for most parameters (exception total iron short-term WQG-AL) in Davidson Creek were greater in operations (Table 2.3-6). However, only the dissolved cobalt frequency and magnitude of exceedance (41.7%, 2.93-times the WQG-AL) increase from no exceedances in baseline or construction suggest a Mine-related effect. Although the total aluminum frequency and magnitude of exceedance increased from baseline to operations, there were sporadic exceedances (less than 10%) of the dissolved aluminum SBEB during operations suggesting no Mine-related effects. At DC-05 in Davidson Creek, the frequency of dissolved aluminum YDWL standard exceedances during operations was similar to the construction period; however dissolved manganese exceedances at DC-05 were observed in operations and not during the construction years (Table 2.3-7).

Exceedances of WQG-ALs were observed at Creek 661 sites for total aluminum (March to July) and total iron (April to September; Table 2.3-3). The magnitude of exceedance for total aluminum at 661-10 ranged from 1.05-times to 5.61-times greater than WQG-AL. The magnitude of exceedance for total iron at 661-10 ranged from 1.17-times to 6.07-times greater than the WQG-AL. Dissolved iron exceedances of the BC short-term WQG-AL were observed at site 661-01 (April) and site 661-10 (July to September) and the magnitude of exceedance ranged from 1.58 to 4.51-times the WQG-AL (Table 2.3-3). Exceedance of the long-term total arsenic WQG-AL was observed at 661-10 (August), and an exceedance of the total mercury BC long-term WQG-AL was observed at 661-03 (April; Table 2.3-3). The spurious exceedances are likely not related to the Mine and were also low magnitude (i.e., less than 5% of guideline). In addition, upstream stations (661-03, 661-04, and 661-05) did not show corresponding increases of dissolved iron or total arsenic during these periods, indicating there was no upstream-to-downstream gradient and elevated concentrations at 661-10 are not entirely associated with Mine-related sources.

Dissolved zinc exceedances were observed at 661-04 in most months (January to September, and December) and at 661-10 in February (Table 2.3-3). Dissolved zinc at 661-04 ranged in magnitudes between 1.02-times to 2.82-times the WQG-AL. The surface water quality results indicated there were no or limited long-term effects to aquatic life at most Creek 661 sites because exceedances were low in magnitude and/or also observed at the upstream control site 661-01. Although total and dissolved iron at 661-10 in mid- to late-summer and dissolved zinc

at 661-04 exceedances occurred more frequently and at greater magnitude than at 661-01, (Table 2.3-3) the available data does not indicate exceedances are entirely Mine-related. The 2022 monitoring data demonstrates that several parameters occurred at or above their respective WQG-ALs during that period, indicating that elevated concentrations of these parameters in 2025 are likely consistent with natural background variability (and the wildfires) rather than entirely Mine-related changes.

Compared to baseline, WQG-AL exceedances at Creek 661 sites were similar in frequency and/or magnitude in operations (Table 2.3-6). Dissolved zinc was an exception with a greater frequency and magnitude of exceedances in operations when compared to both baseline and construction (Table 2.3-6). The dissolved zinc exceedances were typically observed at site 661-04 and in 10 of 12 months in 2025. Although the magnitude of exceedance was (less than 2.5-times the WQG-AL), the increased frequency from baseline suggests a Mine-related effect at site 661-04. However, the decreasing trend in magnitude from 2.45-times in January to no exceedance for October and November, then 1.05-times in December suggest the Mine-related effect were minimal and limited to Q1 of 2025.

Exceedances of the total iron long-term WQG-AL were observed at Chedakuz Creek sites CC-03 (April), CC-05 (May), CC-20 (February and April), CC-30 (April, July, and October) and CC-40 (April to December; Table 2.3-4). The exceedance magnitudes were typically low, ranging from approximately 1.01-times to 2.29-times greater than the WQG-AL. There were no exceedances of the total iron short-term WQG-AL at Chedakuz Creek sites. Short-term dissolved iron exceedances were observed in November at CC-30 and CC-40 with low magnitudes (1.09- and 1.11-times the WQG-AL; Table 2.3-4). The surface water quality results indicated there were no or limited long-term effects to aquatic life at Chedakuz Creek sites because exceedances were typically low magnitude, and where frequent, the magnitude was generally less than 2-times greater than the WQG-AL (Table 2.3-4). The 2025 exceedances of the YDWL standards at CC-15 were limited to dissolved manganese in March to May, August, October, and November and pH (upper) standard in August (Table 2.3-4). Exceedances were also low magnitude (less than 3-times the standard). Relative to baseline, frequencies and magnitudes of WQG-AL exceedances were similar to baseline and construction periods indicating the exceedances are not Mine-related at Chedakuz Creek sites (Table 2.3-6). Similarly, the exceedances of the YDWL standards at Chedakuz Creek site CC-15 in 2025 was similar to the construction period (Table 2.3-7).

Exceedances of the WQG-AL were not observed in 2025 at the Fawnie Creek Tributary stream site (FC-01) or site 705-10 in Creek 705 (Table 2.3-5). At regional control site 705-05, exceedances of the long-term WQG-AL were observed for total iron in July through December with magnitudes ranging from 1.13-times to 4.37-times greater than the WQG-AL (Table 2.3-5). Exceedances of the short-term WQG-AL for total iron and dissolved iron were observed at site 705-05 in August to October with magnitudes of 1.03-times to 2.58-times greater than the WQG-AL (Table 2.3-5). Exceedances of the total and dissolved iron WQG-AL at the regional control site suggest that exceedances at impact sites are related to a regional effect and not Mine-related.

Exceedances of the WQG-ALs were not observed at the Tatelkuz Lake sites (TL-01, TL-02, TL-03, and TL-04) and Kuyakuz Lake site (KL-01) in 2025.

Notes:
NA = Not applicable (the standard was not applicable to the site).
Construction period = October 2022 to 2024; Operations = January to December 2025.
Refer to Table 2.2-2 for Yinka Dene Water Law water quality standard.
Values below detection limit were replaced with half the detection limit for calculations.
Only parameters greater than Yinka Dene Water Law water quality standard are included in the table.
Frequency represents the percentage of the mean monthly samples that were greater than the guideline concentration, and factor (shown in brackets) represents the mean magnitude of the observed exceedances.
[a] Value was equal to the standard value.

2.4 WATER QUALITY RESPONSE FRAMEWORK

2.4.1 METHODS

Water quality parameters to be included in the Water Quality Framework were selected based on the rationale discussed in the AEMP Plan (ERM 2025b):

- Dissolved oxygen
- pH
- TSS and TDS
- Ions: chloride, fluoride, and sulphate
- Total metals: aluminum, antimony, arsenic, barium, beryllium, boron, cadmium, chromium, cobalt, copper, iron, lead, manganese, mercury, molybdenum, nickel, selenium, silver, strontium, thallium, uranium, vanadium, and zinc
- Dissolved metals: aluminum, cadmium, copper, iron, manganese, and zinc

Dissolved cobalt was added because of the exceedances of WQG-AL in Davidson Creek. For all NPMs the evaluation of results against NPMs for water quality was based on near-field sites. The near-field sites represent sites closest to the influence of the mine site discharge points and non-point source seepage. For the construction and operations period, the effects of the Mine on surface water are likely to be most apparent at the near-field sites, including:

- Davidson Creek: DC-05, DC-10, and DC-15; and
- Creek 661: 661-03, 661-04, 661-05 and 661-10.

Water quality NPMs and management responses for each action level are provided in Table 5.2-2 of the AEMP Plan (ERM 2025b). Water quality guidelines for several parameters are based on concentrations of toxicity modifying factors (e.g., hardness, DOC). For these parameters, water quality guidelines were calculated for each sample based on the concentration of the parameter and toxicity modifying factors in the same sample, as recommended by BC MOE (2016b).
The specific NPMs baseline concentrations (95th percentile plus 20%) are provided in tables in Appendix A-11 and NPMs used for predicted concentrations are provided in Appendix A-13.

2.4.2 RESULTS

To meet the "none" NPM for water quality the mean monthly measured water quality parameter concentration meets the following conditions:

- **[Condition 1]** lower than the WQG-AL, Water Quality Guideline for the protection of wildlife (WQG WL) or approved SBEB (BC WLRS 2025a, 2025b, 2023a; CCME 2025a); and
- **[Condition 2]** less than or equal to (a) the 95th percentile of the predicted concentration (base case) in the same month or (b) the 95th percentile baseline concentration plus 20% in the same month.

Water quality concentrations at the near-field sites meeting both conditions indicate that there is no requirement for a change to current mitigation measures. At the "none" action level, water

quality concentrations are below levels of concern and water quality is in the range predicted by the surface water quality model or within site specific baseline concentrations.

At each of the evaluated sites (DC-05, DC-10, DC-15, 661-03, 661-04, 661-05, and 661-10) Condition 1 was not met (Section 2.3.4) and Condition 2 (Table 2.3-2 and Appendix B-12) was not met for all measured water quality parameters in one or more months during construction. Therefore, results of the comparison to the "low" NPM for Condition 1, 2a and Condition 2b was completed (Figure 2.4-1).

To exceed the "low" NPM for water quality the mean monthly measured parameter concentrations in water in two or more consecutive months meets the following conditions:

- **[Condition 1]** lower than the WQG-AL, Water Quality Guideline for the protection of wildlife (WQG WL) or approved SBEB (BC ENV 2024a, 2024b, 2023a; CCME 2024a); and
- **[Condition 2]** higher than (a) the 95th percentile of the predicted concentration (base case) in the same month and (b) the 95th percentile baseline concentration plus 20% in the same month; and
- **[Condition 3]** changes in concentration are not statistically significant between near-field and control sites or compared to baseline conditions (BACI analysis).

Typically, all water quality parameters did not meet all conditions of the "low" action level indicating that the parameter concentrations have increased when compared to baseline but are below levels of concern (Figure 2.4-1). However at Davidson Creek sites (DC-05, DC-10, DC-15) the following parameters met conditions of the "low" action level indicating changes are greater than predicted and baseline conditions in the same two or more consecutive months but not statistically significant (BACI results were not significant or not completed) were chloride, total arsenic (DC-10 and DC-15), total copper (DC-05 and DC-15), and total lead (Figure 2.4-1). Parameters meeting Condition 2 (greater than baseline and predicted concentrations in the same two or more consecutive months) and changes were statistically significant (Condition 3) were evaluated as meeting the "medium" action level. At Davidson Creek sites parameters meeting the "medium" action level were total aluminum, total arsenic (DC-05), total barium, total iron (DC-10 and DC-15) and total uranium (Figure 2.4-1). Graphical analysis indicates concentrations of parameters meeting the "low" and "medium" action levels were related to the contribution of particulate-bound metals from overland flow from the 2023 fire-impacted upper Davidson Creek watershed to Davidson Creek (either directly or via non-contact water diversions), the March 2025 TSS laden water release into Davidson Creek, and the tree clearing that was completed upstream of Davidson Creek in May/June 2025.

The Q4 groundwater concentrations in monitored groundwater wells downstream of the TSF C were greater than predicted (Year 1 TSF Seepage Predictions) for sulphate, nitrogen species, dissolved cobalt, chromium, nickel, silver, copper, and WAD cyanide (KP 2026b). Thus, greater concentrations of copper ("low" action level) are likely associated with unrecovered seepage from TSF C. Cadmium and lead concentrations ("medium" action level) Q3 and Q4 concentrations were greater than baseline but cannot be confirmed as a Mine-related effect based on the observations in downstream groundwater monitoring wells (KP 2026b) and more likely related to the wildfire, TSS laden water release, and tree clearing.

Notes: *Dashes indicate: the Construction and Operation mean monthly concentration was less than than the WQG-AL and WQG-WL or approved SBEB (Section 2.3.3); or the Construction and Operation mean monthly concentration was less than the 95th percentile of the predicted concentration (base case) in the same month or less than the corresponding monthly 95th percentile baseline concentration plus 20% (Appendix A-11 and Appendix A-13).*
BACI = Before-after-control-impact; NG = no guideline; SBEB = Science-based Environmental Benchmark; WQG-AL = water quality guideline for the protection of aquatic life; WQG-WL= water quality guideline for the protection of wildlife.
**Significant BACI result but not related to 2025 Mine activities.*

Action Levels None Low Medium High

ERM

CLIENT: BW Gold LTD.
GRAPHICS NUMBER: BWG-26ERM-015:1

The following parameters met conditions of the "low" action level at one or more Creek 661 sites: pH, TSS, TDS, chloride, sulphate, total antimony, beryllium, cadmium, chromium, copper, iron, lead, manganese, molybdenum, nickel, selenium, vanadium, zinc, and dissolved aluminum, cadmium, copper, iron, manganese, and zinc. Although there were significant BACIs for pH, TDS, strontium, and dissolved iron these were not considered "medium" action levels given the uncertainty in baseline trends at site 661-04 or they were not Mine related (i.e., significance was related to increases observed at downstream sites). Therefore, Creek 661 site parameters meeting the "medium" action level were total arsenic (661-04 and 661-05), total barium (661-04 and 661-05), total uranium, and dissolved zinc (661-04; Figure 2.4-2).

Graphical analysis indicated that most metals (total arsenic, barium, beryllium, cadmium, chromium, cobalt, copper, lead, manganese, and zinc, and dissolved manganese, and zinc) that were elevated at sites 661-04, 661-05 and 661-10 during Q1 of 2025 were likely related to 2025 construction activities. Greater concentrations are also likely associated with overland flow through the 2023 and 2024 fire-impacted areas around the Creek 661 tributaries located within the Mine site. Following the comparison of May 2025 and 2024 water quality at the Creek 661 sites, it was determined that elevated total and dissolved copper, total and dissolved cadmium, and total and dissolved zinc were likely associated with dust or particle erosion following the ore stockpile dust event (Lorax 2025). BW Gold investigated wind fencing to mitigate dusting from the ore stockpile drop points, but this option was deemed not feasible as the design criteria did not prove to be effective for dust management (Environmental Life of Mine Committee [ELoMC] meeting minutes, August 28, 2025). Following notification from BC EAO in May 2025, BW Gold implemented mitigation measures to minimize the dust from the ore stockpile (i.e., operational spray bars installed at the primary crusher, the conveyor, and the ore stockpile drop points; the secondary crusher is enclosed, and therefore no spray bars were needed). The 2025 June to December total metal concentrations were typically similar to that observed in the same months during the baseline period. Thus, mitigations appear to be successful. In September 2025 BW Gold announced that it would be constructing a cover on its crushed ore stockpile as part of the Phase 1A expansion. In addition, dusting plumes generated from road use are documented in the visual dust observation log. BW Gold is actively implementing dust mitigation measures (in accordance with the Air Quality and Fugitive Dust Management Plan) in response to dust observations.

A "high" action level (i.e., concentrations have increased in a manner not predicted by the surface water quality model, are higher than baseline concentrations, and are greater than WQG-AL in the same two or more consecutive months) was met for total aluminum (661-04, 661-05 and 661-10), and total iron (DC-05). Dissolved cobalt (DC-05, DC-10, DC-15) was considered to meet the "high" action level because the 2025 concentrations were higher than baseline concentrations and WQG-AL exceedances were observed in the same months.

As defined in the AEMP Plan (ERM 2025b) responses to triggering a "high" action level include:

- Actions implemented as defined in the associate separate Trigger Response Plan for Authorized Discharges to Davidson Creek applicable to the discharge and receiving environment as defined in the EAC #M19-01 Condition 26.
- Investigate to confirm root cause of changes in water concentrations.

Notes: *Dashes indicate: the Construction and Operation mean monthly concentration was less than than the WQG-AL and WQG-WL or approved SBEB (Section 2.3.3); or the Construction and Operation mean monthly concentration was less than the 95th percentile of the predicted concentration (base case) in the same month or less than the corresponding monthly 95th percentile baseline concentration plus 20% (Appendix A-11 and Appendix A-13).*
BACI = Before-after-control-impact; NG = no guideline; SBEB = Science-based Environmental Benchmark; WQG-AL = water quality guideline for the protection of aquatic life; WQG-WL= water quality guideline for the protection of wildlife.
**Significant BACI result but not related to 2025 Mine activities.*

Action Levels *None* *Low* *Medium* *High*

ERM

CLIENT: BW Gold LTD.
GRAPHICS NUMBER: BWG-26ERM-015:2

- Implement new mitigation measures or adjust existing mitigation measures to address root cause.
- Implement a water sampling program to define the magnitude, spatial extent, and reversibility of the effect.
- If metal concentrations are meeting the NPMs for "high" action levels in water, implement a water-dependent wildlife study and as developed at the "medium" action level; and
- Implement monitoring to assess effectiveness of mitigation options.

Additional responses may include:

- Evaluate if an ecological risk assessment is required to identify spatial extent, magnitude, and reversibility of the effect.
- Review the water quality guidelines, or approved SBEB and propose a new SBEB, if appropriate.

Graphical analysis indicates concentrations of total iron at Davidson Creek sites were generally lower when compared to 2024 concentrations and similar to baseline. This trend suggests the statistically significant effect is largely attributed to the 2024 activities (i.e., initiation of discharge from TSFC-SCP to Davidson Creek). No effects to aquatic life are expected given acute toxicity thresholds were met, and the magnitude of the total iron WQG-AL exceedances were low at DC-05 (range from 1.22 and 2.21 times the guideline for total iron). Thus, no changes to the current erosion and soil mitigations are required in response to the "high" action exceedance.

Graphical analysis indicates that dissolved cobalt concentrations at Davidson Creek sites are likely associated with unrecovered seepage from the TSF C and this is confirmed with results of the groundwater monitoring program (KP 2026b). The magnitude of the dissolved cobalt exceedances at DC-05 and DC-10 in November and December 2025 (i.e., greater than four-times the guideline) if persistent, could have the potential for certain limited long-term effects to aquatic life as described below. Dissolved cobalt will continue to be monitored in accordance with regulatory requirements. BW Gold implemented mitigation measures (described below) to capture Mine-related sources downstream of the TSF C in late 2025 and early 2026 and is permitted to construct additional structures downstream of the present extent of Mine-related sources of water that are expected to provide further mitigation. BW Gold plans to commence construction of these structures in 2026. These mitigation measures are expected to positively impact water quality in future years.

The dissolved cobalt WQG-AL (ENV 2025) was calculated from the lowest available toxicity data point from an Environment Canada literature review published in 2017 with a 2-fold assessment factor applied to account for uncertainty in terms of extrapolating from a small number of laboratory test organisms to the broader aquatic community present in the receiving environment. The lowest available toxicity data point was a 28-day Effect Concentration (EC_{10}) for the amphipod, *Hyalella azteca*, followed closely by EC_{10} for growth of an aquatic plant (duckweed) and an EC_{10} for reproduction of cladocerans. Toxicological thresholds are much higher for species that are more directly representative of the aquatic community in Davidson Creek (i.e., salmonid fish). Thus, the potential adverse effects may be limited to the lower trophic levels (i.e., invertebrates and periphyton). Chronic toxicity testing, periphyton monitoring, and benthic invertebrate monitoring were completed at DC-05 in September 2025 and result summaries are provided in

Sections 3.4, 3.5, and 3.6. The September 2025 results do not suggest impairment in the lower trophic communities that could be associated with dissolved cobalt and there were no effects to fish communities.

Water-dependent wildlife studies are not required at this time, given the total cobalt BC livestock watering guideline is 1 mg/L (BC WLRS 2025b) and total cobalt concentrations in Davidson Creek ranged from less than the detection limit to 0.001 mg/L.

Monitoring results in Davidson Creek and Chedakuz Creek (downstream of the confluence with Davidson Creek) suggests the spatial extent of the dissolved cobalt increase has extended as far as CC-20 in Chedakuz Creek (Figure A7-44). However, the dissolved cobalt WQG-AL was not exceeded at any of the Chedakuz Creek sites (Table 2.3-5). Continued monitoring at Davidson Creek and Chedakuz Creek sites throughout 2026 will be completed. BW Gold planned/completed mitigations to address the "high" action level exceedance are:

1. Additional monitoring of TSF C seepage flow paths entering the former Davidson Creek upstream of the future FWR footprint.
2. Additional monitoring (increase frequency) of installed groundwater wells and installation and monitoring of new groundwater wells downstream of the TSF C to understand seepage flows and flow paths.
3. Commencement of operation of two seepage pump back wells in September 2025.
4. Capture and pump back of seepage reporting to a topographic low point downstream of TSF C.
5. Installation of four additional seepage pump back wells (pumping from three of the wells was initiated at the end of period in February 2026 and one well remains on stand-by pending monitoring results).
6. Execution of site investigations and engineering design for the ECD, Northern Diversion, and TSF D which are planned to be constructed in accordance with the mine development sequence (ECD and Northern Diversion in 2026, TSF D commencing in 2027) and are expected to contribute to seepage capture or routing of clean water away from the Mine areas.

Reduction of dissolved cobalt is anticipated with the mitigations however following assessment of the monitoring results in 2026, BW Gold will evaluate if additional mitigations are necessary and/or if a dissolved cobalt SBEB is required.

At 661-04, 661-05 and 661-10, no effects to aquatic life are expected given the frequency and magnitude of the long-term total aluminum WQG-AL exceedances were low (the magnitude ranged from 1.05 to 5.61). The total aluminum concentrations that exceeded the WQG-AL with the greatest magnitude occurred in March and likely associated with the overland flow over the 2023 and 2024 wildfire impacted areas during the spring melt and not a Mine-related effect. Exceedances of the WQG-AL were also observed in 2024 at a greater magnitude, and concentrations in Q3 and Q4 were well below the WQG-AL (Figure 2.3-29). Therefore, it is anticipated that exceedances will be less frequent in future monitoring years as the wildfire impacted areas recover and no additional mitigations are required.

2.5 SUMMARY AND RECOMMENDATIONS

The 2025 water quality at Davidson Creek sites indicated that most concentrations were similar or greater than baseline years and below levels of concern. However, there were parameters that were greater than baseline and concentrations predicted by the water quality model in two or more consecutive months: chloride, total arsenic, total copper, and total lead. Parameters with concentrations identified as Mine-related significant increases from baseline concentrations (determined by statistical analysis) were total aluminum, arsenic (DC-05), barium, iron (DC-10 and DC-15), and uranium. Graphical analysis indicates concentrations of parameters that have increased when compared to baseline and evaluated as meeting a "low" or "medium" action level were likely related to the contribution of particulate-bound metals from overland flow from the 2023 fire-impacted upper Davidson Creek watershed to Davidson Creek (either directly or via non-contact water diversions), the March 2025 TSS laden water release to Davidson Creek and the May and June 2025 tree clearing activities adjacent to the FWR. A "high" action level (i.e., concentrations have increased in a manner not predicted by the surface water quality model, are higher than baseline concentrations, and are greater than WQG-AL in the same two or more consecutive months) was met for total iron (DC-05). Dissolved cobalt (DC-05, DC-10, DC-15) was considered to meet the "high" action level because the 2025 concentrations were higher than baseline concentrations and WQG-AL exceedances were observed in the same months. Graphical analysis indicates dissolved cobalt concentrations at Davidson Creek sites are likely associated with unrecovered seepage from the TSF C and confirmed based on the groundwater monitoring results (KP 2026b).

No effects to aquatic life are expected given acute toxicity thresholds were met, and the magnitude of the total iron WQG-AL exceedances were low at DC-05 (range from 1.22 and 2.21 times the guideline for total iron). However, the magnitude of the dissolved cobalt exceedances at DC-05 and DC-10 in November and December 2025 (i.e., greater than four-times the guideline) if persistent, could have the potential for certain limited long-term effects to aquatic life. Examination of the toxicity data used to generate the dissolved cobalt WQG-AL suggests that the potential for long-term effects may be limited to the lower trophic levels (i.e., invertebrates and periphyton). However, results of September 2025 chronic toxicity testing, periphyton monitoring, and benthic invertebrate monitoring at DC-05 do not suggest impairment in the lower trophic communities that could be associated with dissolved cobalt. Dissolved cobalt will continue to be monitored in accordance with regulatory requirements. BW Gold implemented mitigation measures to capture Mine-related sources in late 2025 and early 2026 and is permitted to construct additional structures downstream of the present extent of Mine-related sources of water that are expected to provide further mitigation. BW Gold plans to commence construction of these structures in 2026. These mitigation measures are expected to positively impact water quality in future years. BW Gold continues to monitor the effectiveness of these actions.

The 2025 water quality at Creek 661 sites were typically similar or greater than baseline concentrations and concentrations were below levels of concern. However, there were parameters that met conditions of the "low" action level at one or more Creek 661 sites: pH, TSS, chloride, sulphate, total antimony, total cadmium, total chromium, total copper, total iron, total lead, total manganese, total molybdenum, total nickel, total selenium, total vanadium, total zinc, dissolved

aluminum, dissolved cadmium, dissolved copper, dissolved iron, dissolved manganese, and dissolved zinc. At Creek 661 sites, the parameters meeting the "medium" action level were total arsenic (661-04 and 661-05), total barium (661-04 and 661-05), total uranium (661-03, 661-04, 661-05, and 661-10), and dissolved zinc (661-04). Graphical analysis did not confirm that increases at Creek 661 sites were entirely related to the 2025 Mine activities. Greater concentrations are also likely associated with overland flow through the 2023 and 2024 fire-impacted areas around the Creek 661 tributaries located within the Mine site. Following the comparison of May 2025 and 2024 water quality at the Creek 661 sites, it was determined that elevated total and dissolved copper, total and dissolved cadmium, and total and dissolved zinc were likely associated with dust or particle erosion following the ore stockpile dust event (Lorax 2025). BW Gold initiated mitigation measures in May 2025 in response to the dust event and water quality at Creek 661 sites in Q3 and Q4 was similar to baseline years indicating the effect was not persistent through 2025 and not likely to affect aquatic life during the highest period of productivity in late August/early September.

A "high" action level was met for total aluminum (661-04, 661-05, and 661-10) and was most likely associated with overland flow through the 2023 and 2024 fire-impacted areas around the Creek 661 tributaries located within the Mine site and 2025 construction activities. The greatest frequency and magnitude of WQG-AL exceedances tended to occur in March 2025 (and likely as a result of high TSS). Exceedances of the WQG-AL were also observed in 2024 at a greater magnitude, and concentrations in Q3 and Q4 were well below the WQG-AL. Therefore, it is anticipated that exceedances will be less frequent in future monitoring years as the wildfire impacted areas recover and no additional mitigations are required.

Significant increases from baseline (determined by statistical analysis) in pH, turbidity, sulphate, total ammonia-N, total aluminum, total barium, total iron, total and dissolved manganese, and total uranium tended to be at Chedakuz Creek sites downstream of the confluence with Davidson Creek (CC-15, CC-20, and CC-40 but not CC-30). It was concluded that greater concentrations of turbidity, total aluminum, and total barium at sites CC-15 and CC 20 may be related to 2024 and 2025 Mine activities (i.e., upstream of DC-20). However, given there was no decreasing trend with downstream distance between sites CC-15 and CC-40, it was concluded that the increasing concentrations at CC-40 are not entirely related to Mine activities. There are several anthropogenic sources that may contribute to Chedakuz Creek water quality and at site DC-20 (e.g., forest harvesting activities, road/trail networks, cattle grazing). Thus, it was concluded that other non-Mine related sources have also contributed to the observed increases in CC-15, CC-20, and CC-40. Mitigation in response to Mine-related changes in water quality identified in Davidson Creek are expected to also address Mine-related increases in Chedakuz Creek.

Turtle Creek sites (TC-05, TC-10, and TC-15) are located in the watershed where the Mine airstrip would be located therefore statistical analysis was not completed for Turtle Creek sites because the airstrip has not been constructed.

Tatelkuz Lake physical profiles indicated that the lake was fully mixed in the winter and tended to be stratified in the spring, summer, and fall (e.g., May, August, September, October, and November). However, Kuyakuz Lake profiles indicated the lake generally does not stratify throughout the year, with May 2023 being an exception. Both lakes exhibited similar water quality and lakes exhibited

differences with depth (i.e., greater total phosphorus concentrations in the deepest layer). Total and dissolved metals were low among all lake sites and typically less than detection at all depths sampled. The results of surface water quality monitoring in lakes indicated no Mine-related effects in Tatelkuz Lake.

No additional sampling or analyses other than that described in the AEMP Plan, Version 4.0 (ERM 2025b) is recommended.

3. CHRONIC TOXICITY TESTING

3.1 MEASUREMENT AND ASSESSMENT ENDPOINTS

Surface water toxicity testing as chronic or sublethal toxicity testing was assessed based on the calculation of the LC_x (lethal concentration that causes mortality in x% of test organisms), EC_x (effect concentration that causes effects in x% of test organisms), or the IC_x (concentration that results in inhibition in x% of the test organisms) as shown in Table 3.1-1. The "x" is defined by the standardized Environment Canada methodologies (see Section 3.2.2).

TABLE 3.1-1 MEASUREMENT AND ASSESSMENT ENDPOINTS FOR SURFACE WATER TOXICITY

Measurement Endpoint	Assessment Endpoint
Surface water toxicity testing (growth, reproduction, or survival)	Calculation of LC_x, EC_x or IC_x[1]

Notes:
EC = Effective Concentration; IC = Inhibition Concentration; LC= Lethal Concentration
[1] Test species for fish species: fathead minnow or rainbow trout; invertebrate species: *Ceriodaphnia dubia;* plant species: Lemna minor; and an algal species.

3.2 SAMPLING SITES AND METHODS

As defined in the AEMP Plan (ERM 2025b), chronic toxicity testing samples were collected at sites downstream from the Mine and control sites, as indicated in Table 1.7-2, at the frequencies identified in Table 1.7-3.

3.2.1 FIELD METHODS

Surface water (for chronic toxicity testing) was collected at two near-field sampling sites downstream from the mine site (DC-05 in Davidson Creek and 661-10 in Creek 661) and at two control sites (FC-01 in Fawnie Creek and 661-01 in Creek 661) on September 14, 2025 (Table 1.7-2 and Figure 1.7-2). Chronic toxicity surface water samples were collected concurrently with the surface water quality samples using the methods in Section 2.1.1. A sample from 661-01 was collected on September 30, 2025, to repeat the fathead minnow (*Pimephales promelas*) toxicity test after the initial test (VA25C4197-004) failed to meet the required validity criteria. Samples were kept cool and dark and shipped to Nautilus Environmental Company Inc. (Nautilus; as subcontracted by ALS) in Burnaby, BC for analysis.

3.2.2 LABORATORY METHODS

Chronic toxicity testing was conducted by Nautilus using the following test methodologies, as defined in Schedule 5 (Environmental Effects Monitoring Studies) of the MDMER (Government of Canada 2025) and PE-110652, Appendix B:

- Fish species were assessed using the Biological Test Method: *Test of Larval Growth and Survival Using Fathead Minnows* (Environment Canada 2011). Testing was conducted on fathead minnows because viable early life stage rainbow trout were not available for the Biological Test Method: *Toxicity Tests Using Early Life Stages of Salmonid Fish* (Rainbow Trout; Environment Canada 1998) required in Section 4.6 of PE-110652.

- Invertebrate species were assessed using the Biological Test Method: *Test of Reproduction and Survival Using the Cladoceran* Ceriodaphnia dubia (Environment Canada 2007a).
- An algal species was assessed using the Biological Test Method: *Growth Inhibition Test Using a Freshwater Alga* (Environment Canada 2007b).
- Plant species were assessed using the Biological Test Method: *Test for Measuring the Inhibition of Growth Using the Freshwater Macrophyte*, *Lemna minor* (Environment Canada 2007c).

The fathead minnow (*Pimephales promelas*) tests were initiated on September 17 and October 2, 2025, at the Nautilus Point Edward, Ontario (ON) location. Testing for *C. dubia* was performed by Bureau Veritas and these tests were initiated on September 17, 2025. The *L. minor* tests was initiated on September 17, 2025, at the Nautilus Guelph, ON location and the freshwater algal (*Pseudokirchneriella subcapitata*) test was initiated on September 16, 2025, at the Calgary, AB location. All testing was initiated between three and five days after sample collection from field sites.

Toxicity testing was based on a dilution series where the surface water sample is diluted in the laboratory and effects on exposed organisms are measured over time. The LC_x, EC_x or IC_x concentration is reported based on the dilution of water associated with the effect (i.e., concentrations reported in percent volume/volume, % v/v). When the undiluted water has no effect, the LC_x, EC_x or IC_x was reported as greater than 100% v/v. Where the LC_x, EC_x or IC_x is less than 100% v/v, it indicates that the tested sample can cause adverse effects to laboratory organisms and indicates that there is potential for toxicity to occur in the source waters. However, effects in a laboratory-based toxicity test do not necessarily mean that adverse effects will occur in source waters, because the types of organisms used in the tests may not fully represent those in the source waters (e.g., organisms in the source waters may have adapted to the conditions in ways that laboratory organisms are not). It is not unusual to find that natural, non-impacted surface waters (e.g., control sites) can cause adverse effects (an LC_x, EC_x or IC_x of less than 100% v/v) in laboratory organisms.

3.2.3 DATA ANALYSIS

Upon completion of each laboratory-based chronic toxicity test, the endpoint (e.g., growth, reproduction, or survival) was evaluated statistically to determine the LC_x (mortality), EC_x (embryo viability), or IC_x (inhibition of growth or reproduction). Statistical analysis for all toxicity tests was performed using the Comprehensive Environmental Toxicity Information System (Tidepool Scientific Software, version 2.1.5.5, 2022). Geometric means and ± 95% confidence intervals were presented, where available.

Results of the chronic toxicity testing were interpreted based on a comparison between control and impact (downstream of the Mine) sites, as well as considering results of the co-collected water quality data.

3.2.4 QUALITY ASSURANCE/QUALITY CONTROL

The chronic toxicity testing program included laboratory QA/QC procedures that are required by the test protocols (e.g., use of negative controls, reference toxicant tests, maintaining consistent test conditions, monitoring water quality, and internal QA/QC review prior to release of test results).

3.3 RESULTS AND DISCUSSION

Laboratory reports are provided in Appendix A-15.

3.3.1 FATHEAD MINNOW SURVIVAL AND BIOMASS

Pimephales promelas (fathead minnow) mean survival (± standard deviation) ranged from 86.7 ± 15.3% to 100%, and LC_{50} values were >100% at all sites meeting validity criteria (i.e., sites DC-05, 661-10, and FC-01). The results indicate there were no adverse effects on larval survival at the tested concentrations for both the impact (DC-05, 661-10) and control (FC-01) sites. Mean biomass (± standard deviation) ranged from 0.56 ± 0.07 mg to 0.77 ± 0.04 mg, and IC_{25} values were >100% for all samples, demonstrating no inhibition of growth.

The fathead minnow test for station 661-01 did not meet test validity criteria and a replacement grab sample was collected on September 30, 2025, to repeat the 7-day test. Mean survival (± standard deviation) ranged from 80.0 ± 10.0% to 100%, and the LC_{50} was >100%. Biomass ranged from 0.61 ± 0.12 mg to 0.79 ± 0.02 mg, and the IC_{25} was >100%. Adverse effects of water from site 661-01 were not detected on fathead minnow growth or survival.

3.3.2 *CERIODAPHNIA DUBIA* SURVIVAL AND REPRODUCTION

Ceriodaphnia dubia survival (water flea; LC_{50} value) was >100% for sites DC-05, FC-01, and 661-01. The dose-response curve for survival at 661-10 did not allow calculation of an LC_{50}, despite the test meeting validity criteria. Mean brood sizes (± standard deviation) ranged from 0 to 28 ± 3.5 neonates per adult at all sites. The IC_{25} values were >100% for FC-01 and 661-01 and 87.1% (34.5%-NA) for DC-05. Reproduction of *C. dubia* was less than 100% in water collected from site 661-10 (IC_{25} = 28.8% and ranged between 18.0% and 32.0%). Overall, no mortality-related effects on *C. dubia* were observed at either impact or control sites, but reproduction of *C. dubia* was inhibited by water samples from sites DC-05 and 661-10 in 2025. Water quality parameters greater than WQG-AL at the sites were total aluminum (DC-05 and 661-10), total arsenic (661-10), total cadmium (DC-05 and 661-10), dissolved cobalt (DC-05), total and dissolved iron (DC-05 and 661-10), and dissolved zinc (DC-05 and 661-10) and may have contributed to reduced reproduction.

3.3.3 *PSEUDOKIRCHNERIELLA SUBCAPITATA* 72-HOUR GROWTH INHIBITION

Growth of *Pseudokirchneriella subcapitata* (green algae) (± standard deviation) ranged from approximately 243 $x10^3$ (± 15.1) to 559 $x10^3$ (± 20.2) cells per mL across sites and test concentrations. Water from sites DC-05, 661-10, and FC-01, produced no inhibitory effects on growth rates, where IC_{25} values were >91% for each site. At site 661-01, decreasing cell yields were observed with increasing site water concentrations. Inhibitory effects on growth were detected with an IC_{25} of 48.7% (range of 41.1% to 56.7%), with up to 56.6% inhibition at the highest test site water concentration.

Growth responses in *P. subcapitata* can reflect hormesis or the presence of constituents that either stimulate or inhibit growth depending on concentration; in 2025, the response pattern was characterized by negligible growth inhibition at three stations and inhibitory effects on cell growth

in water from the control site; 661-01. Overall, there was no evidence of Mine-related effects, where growth inhibition occurred only at a control site and not at any near-field impact sites. The 2025 results differ from previous years (ERM 2023, 2024, 2025a) because the pronounced growth stimulation was not observed; instead, effects ranged from no inhibition (IC_{25} >91%) at impact and control sites (DC-05, 661-10, and FC-01) to inhibition at the control site 661-01.

3.3.4 *LEMNA MINOR* 7-DAY GROWTH INHIBITION

The effects of site water on *Lemna minor* (duckweed) growth inhibition were assessed using frond number and dry weight of plant material. Frond growth (measured as an increase in number of fronds; ± standard deviation) ranged from approximately 53 ± 2.8 to 155 ± 9.0 across all tested concentrations and sample sites, and IC_{25} values for frond number were greater than the maximum concentration tested (>97%) at all sites. Dry weight of plant materials ranged from approximately 6.1 ± 0.5 mg to 15.7 ± 1.7 mg, and IC_{25} values for dry weight were also greater than the maximum concentration tested (>97%).

Overall, the 2025 results showed no growth-inhibition on *L. minor* at any impact or control site. Growth stimulation occurred at several concentrations, including increases in both frond number and dry weight at sites 661-10, FC-01, and 661-01. These results are consistent with chronic toxicity testing completed in previous years (ERM 2023a, 2024, 2025a).

3.3.5 QUALITY ASSURANCE/QUALITY CONTROL

All test organisms met required health criteria, and control performance satisfied the Environment Canada protocol validity requirements (Environment Canada 2007a, 20027b, 2007c, 2011). Water quality parameters remained within acceptable ranges throughout testing. The only deviation noted was that the September 14 fathead minnow test for 661-01 did not meet control validity criteria; this test was repeated with a new sample collected on September 30 to generate valid results. All reference toxicant tests were within acceptable limits, indicating reliable test performance. No other deviations were reported.

3.4 SUMMARY AND RECOMMENDATIONS

The chronic toxicity testing indicated that fathead minnow survival and growth, and *C. dubia* survival were not affected in water collected from both impact and control sites (Table 3.4-1). However, *C. dubia* reproduction decreased in water collected from impacted sites DC-05 and 661-10, while the control sites FC-01 and 661-01 had no reproductive inhibition (Table 3.3-1). The *C. dubia* reproduction inhibition at DC-05 and 661-10 does not necessarily suggest a Mine-related effect given only dissolved cobalt exceedances of the WQG-AL at DC-05 were identified as Mine-related effects (Section 2.3.3). Algal growth inhibition was observed only at the control site 661-01, while DC-05, 661-10, and FC-01 had no effects (Table 3.4-1). The 661-01 water hardness was moderately lower (14 mg/L) when compared to other site tests (40 mg/L) which may have contributed to the growth inhibition (Lasier et al. 2006). There was no growth inhibition of *L. minor* in water from any site, although some growth stimulation was observed at several concentrations of water from control and impact sites (Table 3.4-1). Based on this, continued

toxicity testing under the AEMP Plan, Version 4.0 (ERM 2025b) is recommended, and no changes are recommended beyond existing program requirements.

TABLE 3.4-1 SUMMARY OF CHRONIC TOXICITY TESTING RESULTS, 2025

Organism	Endpoint	Impact Sites % v/v (± 95% CI)		Control Sites % v/v (± 95% CI)	
		DC-05	661-10	661-01	FC-01
Pimephales promelas	Survival LC_{50}	>100	>100	>100[1]	>100
	Biomass IC_{25}	>100	>100	>100[1]	>100
Ceriodaphnia dubia	Survival LC_{50}	>100	-[2]	>100	>100
	Reproduction IC_{25}	87.1 (34.5-NA)	28.8 (18.0-32.0)	>100	>100
Pseudokirchneriella subcapitata	Growth IC_{25}	>91	>91	48.7 (41.1-56.7)	>91
Lemna minor	Frond count IC_{25}	>97	>97	>97	>97
	Dry weight IC_{25}	>97	>97	>97	>97

Notes:
CI = confidence interval; IC_{25} = 25% inhibition concentration; LC_{50} = 50% lethal concentration; NA = not applicable
[1] The September 14 fathead minnow test at 661-01 did not meet control validity criteria. A replacement sample collected on September 30 was tested, and the results supersede the September 14 results.
[2] Statistical analyses of *C. dubia* survival (LC_{50}) could not be completed due to a non-monotonic dose-response, however the test validity criteria were met.

4. SEDIMENT QUALITY

4.1 MEASUREMENT ASSESSMENT ENDPOINTS

Sediment quality samples were collected at sites downstream from the mine site and at control sites, as indicated in Table 1.7-2 and Figure 1.7-2. The 2025 sediment quality was evaluated with one or more assessment endpoints: baseline data, reference ranges, BACI analysis, and/or comparison to BC or CCME sediment quality guidelines for the protection of freshwater aquatic life (SQG-AL; WLRS 2025b; CCME 2025c; Table 4.1-1).

TABLE 4.1-1 MEASUREMENT AND ASSESSMENT ENDPOINTS FOR SEDIMENT QUALITY

Measurement Endpoint	Assessment Endpoint
Particle size and total organic carbon	• Graphical comparison to baseline data[1]
Sediment quality parameters	• Before-after-control-impact (BACI) analysis[2] • Comparison to sediment quality guidelines for the protection of freshwater aquatic life (BC WLRS 2025b; CCME 2025c)[2]

Notes:
[1] For particle size and total organic carbon (parameters required as part of the benthic invertebrate surveys as per Schedule 5 of the MDMER).
[2] For parameters that have BC or CCME sediment quality guidelines for the protection of aquatic life including arsenic, cadmium, chromium, copper, iron, lead, manganese, mercury, molybdenum, nickel, selenium, silver, and zinc.

4.2 SAMPLING SITES AND METHODS

As defined in the AEMP Plan (ERM 2025b), the number of stream sediment sampling sites have been refined since 2017 to detect Mine-related effects. Beginning in 2022, sediment quality sampling was completed at 11 sites (coinciding with aquatic resource sampling) within the Davidson Creek, Turtle Creek, Creek 661 watersheds in addition to the regional control watersheds, Creek 705 and Fawnie Creek tributary (Table 1.7-2).

4.2.1 FIELD METHODS

Stream sediment sampling was completed consistent with the methods provided in the *British Columbia Field Sampling Manual – Part D* (BC MWLAP 2020). Sampling was completed between September 9 and 17, 2025, concurrent with the aquatic resource sampling.

Five replicates were collected from distinct areas of each stream site (e.g., different stretches of the main channel) covering 50 to 100 m depending on stream size and site access. For each replicate (or single sample) sediment was spooned from the top 3 to 5 cm in the depositional zone (areas of slow-moving water). The subsamples were pooled until sufficient sample was obtained for a complete replicate. Samples were collected with a plastic spoon and homogenized in a plastic bin, before being placed in wide-mouth glass jars (following suggested sample collection by ALS Laboratory and BC MOE sampling protocols). Samples were sealed (no air bubbles) and stored in coolers on ice and/or refrigerated until shipped to ALS (Burnaby, BC), a CALA-certified laboratory for analysis.

4.2.2 LABORATORY METHODS

Whole sediment samples were analyzed for particle size analysis. All metal and total organic carbon (TOC) analysis was conducted on the fraction of the sample smaller than 63 µm (Table 4.2-1), as per guidance from BC MOE (2016a). Results of metals analysis were reported in dry weight (mg/kg).

TABLE 4.2-1 ANALYZED SEDIMENT QUALITY PARAMETERS

Physical Tests, Particle Size, Organic Carbon	Total Metals		
• moisture • pH • gravel (> 2 mm) • sand (2 mm - 63 µm) • silt (63 µm - 4 µm • clay (< 4 µm) • total organic carbon	• aluminum • antimony • arsenic • barium • beryllium • bismuth • boron • cadmium • calcium • chromium • cobalt	• copper • iron • lead • lithium • magnesium • manganese • mercury • molybdenum • nickel • potassium • selenium	• silicon • silver • sodium • strontium • thallium • tin • titanium • uranium • vanadium • zinc

All laboratory analysis was conducted using the lowest possible DL, with targeted DLs at least 10 times lower than sediment quality guidelines or standards, where available (BC ENV 2023b). DLs that did not meet this criterion were flagged during quality assurance and quality control of the data.

4.2.3 QUALITY ASSURANCE/QUALITY CONTROL

Five replicate sediment samples were collected from each site to account for and assess environmental heterogeneity. Five field split samples were collected to assess analytical precision. Chain of custody forms were used for all samples.

Analyses were conducted by a CALA-certified laboratory. The QA/QC principles for sediment quality analysis followed those outlined in guidance documents throughout the laboratory analysis phase (BC ENV 2023b).

Laboratory QA/QC measurements and protocols were completed to determine and confirm the accuracy, sensitivity, precision, and comparability of the data, as recommended by BC ENV (2023b). As defined in Section 2.1.2 laboratory QA/QC for sediment quality included evaluation of holding times, laboratory duplicates, certified reference material spikes, laboratory control samples, and method blanks.

4.2.4 DATA ANALYSIS

For the purpose of calculating summary statistics and presentation, concentrations below the DL were replaced with half the DL (BC MOE 2016b).

4.2.4.1 STUDY QUESTION 1—COMPARISON TO BASELINE

To answer the first study question (*Are AEMP component assessment endpoints at impact sites changing from baseline conditions or reference ranges as a result of the Mine?*), sediment quality in the "after" period (i.e., 2024 and 2025) were compared to baseline years and Year 1 of Construction (2017, 2021, 2022, and 2023). Year 1 of Construction (2023) was added to the "before" period because it was concluded that there were limited construction activities and no surface water discharge in 2023 (ERM 2025b).

For particle size composition and TOC, potential mine-related effects on stream sediments were assessed using graphical analysis to characterize differences observed from baseline years and the "after" period.

For metals that have an SQG-AL, potential Mine-related effects on stream sediments were investigated using BACI analysis (R Core Team 2025), on the following receivers that were directly downstream of surface water discharges to Davidson Creek and/or downstream of construction and operations activities:

- Davidson Creek watershed (DC-05 and DC-15)
- Creek 661 watershed (661-05 and 661-10)

Sites in the Turtle Creek watershed were not included, because there were no construction activities (airstrip construction) in 2025. The impact sites were compared against "control" sites, including the regional control sites (705-05, 705-10, FC-01) and the upstream control site 661-01 in the Creek 661 watershed.

Data transformations (e.g., log transformation) were completed if determined to be appropriate (e.g., to achieve random distribution of residuals). For all effects analyses, statistical results were considered unreliable if more than 70% of the values in the dataset for a parameter are below DLs (i.e., highly censored data).

The BACI analysis introduces a class effect to a mixed model ANOVA, which is based on the classification of a site as an impact or a control site. The mixed model ANOVA also included the fixed effect of period ("before" versus "after"), and random effects of year and site to account for variability across sites and between sediment quality replicates. For the period effect, data were grouped into one of two periods: "before" included baseline years and Year 1 of Construction (2017, 2021, 2022, and 2023) and "after" included construction activities, discharge to Davidson Creek, and operations (2024 and 2025).

A significant interaction between the (time) period and class effects reveals whether any before-after change in the mean parameter concentration that occurred in the impact site has not occurred in the control site. The overall site (control versus impact) and period ("before" versus "after") interaction significance (p-value less than significance level [α] of 0.05) was assessed using an F test. To reduce the number of false positives (Type I error) due to the large number of statistical tests conducted, a multiple test correction was applied to the significance level of 0.05.

It is hypothesized that if mine activities affected sediment quality, then there would be a significant change in sediment quality at near-field impact sites in comparison with the "before" period concentrations or control sites. However, if a change in the mean is detected by the before-after comparison, but the BACI analysis indicates that a parallel change also occurred at the control site

(control versus impact), it is reasonable to conclude that this change is likely a natural phenomenon or unrelated to the Mine activities. Similarly, if a change is detected at mid- or far-field sites but not at near-field sites or the control site, it is reasonable to conclude that this change is likely the result of non-Mine related activities (e.g., wildfire, or forestry or agricultural activities downstream of the Mine and upstream of the sampling site).

A precautionary approach was used to determine if an effect is attributable to the Mine activities in cases of unexplained significant interactions using professional judgement, and/or field data to confirm significantly greater or lower concentrations.

4.2.4.2 STUDY QUESTION 3—COMPARISON TO SEDIMENT QUALITY GUIDELINES

To answer the third study question (*Are AEMP component assessment endpoints at impact sites changing to levels that may be associated with effects as a result of the Mine?*) stream sediment quality observed during 2025 and throughout the monitoring period were compared to BC (BC WLRS 2025b) or federal (CCME 2025c) Sediment Quality Guidelines for the Protection of Aquatic Life (SQG-AL); applicable SQG-ALs (Table 4.2-2).

TABLE 4.2-2 SEDIMENT QUALITY GUIDELINES FOR THE PROTECTION OF AQUATIC LIFE

Parameter	BC Sediment Quality Guideline[1]		CCME Guideline for the Protection of Freshwater Aquatic Life[2]	
	Lower	Upper	ISQG	PEL
Arsenic	5.9	17	5.9	17
Cadmium	0.6	3.5	0.6	3.5
Chromium	37.3	90	37.3	90

Silver	0.5	-	-	-
Zinc	123	315	123	315

Notes:
All units are mg/kg.
Dashes indicate no guideline.
BC = British Columbia, CCME = Canadian Council of Ministers of the Environment, ISQG = Interim Sediment Guideline, PEL = Probable Effects Level
[1] BC Sediment Quality Guidelines for the Protection of Freshwater Aquatic Life (BC WLRS 2025b).
[2] Canadian Sediment Quality Guidelines for the Protection of Freshwater Aquatic Life, Canadian Council of Ministers of the Environment (CCME 2025c).

British Columbia SQG-AL include a lower guideline and an upper guideline to provide a flexible interpretive tool for evaluating the toxicological significance of sediment quality data. Sediment chemical concentrations below the lower guideline are rarely associated with adverse effects on biological communities and concentrations between the lower and upper guideline are occasionally associated with adverse biological effects. Sediment concentrations above the upper guideline are more frequently associated with adverse effects on biological communities. Similarly, the CCME guidelines include the Interim Sediment Quality Guidelines (ISQG) and the Probable Effect Levels (PEL), analogous to the BC lower and upper guidelines. For parameters with both a BC and CCME SQG-AL (arsenic, cadmium, chromium, copper, lead, mercury, and zinc), the guidelines are the same for both jurisdictions. British Columbia provides additional SQG-AL for iron, manganese, molybdenum, nickel, selenium, and silver.

The exceedance of the guideline for each parameter was identified for each site where the frequency is based on all replicates and the magnitude or factor (i.e., by how much the guideline is exceeded) was calculated from the mean exceedance of the subset of concentrations greater than the guideline.

4.2.4.3 QUALITY ASSURANCE/QUALITY CONTROL

For each pair of QA/QC field split sediment samples, the RPD (as defined in Section 2.2.4.4) was calculated.

4.2.5 SPECIAL STUDY—HYDROCARBONS

Sediment samples were collected for analysis of PAHs at Davidson Creek sites DC-05 and DC-15, Creek 661 sites 661-01, 661-05, and 661-10, Turtle Creek site TC-05 and the regional control site 705-05.

Field collection were the same as the regular sediment quality sampling (Section 4.2.1). Laboratory analysis was completed for moisture and PAHs (Table 4.2-3). Laboratory methods were similar to the regular sediment quality samples (Section 4.2.2) with the additional QA/QC laboratory procedures that included analysis of surrogate spikes. Surrogate spikes are addition of a known quantity of a pure compound that is different from but similar enough to the analyte prior to processing to provide a measure of the overall efficiency of the method (recovery).

4.3 RESULTS AND DISCUSSION

Analytical results for the stream sediment quality results are provided in Appendix B-1 and assessment of the QA/QC results, including calculated RPDs of the field split samples are provided in Appendix B-2. Graphical presentation of all parameters and a characterization of the 2025 sediment quality throughout the monitoring periods is provided in Appendix B-3.

Sediment quality concentrations for Turtle Creek sites are plotted on the figures and comparison to guideline results are provided, however they are not discussed further because the airstrip has not been constructed.

4.3.1 STUDY QUESTION 1—COMPARISON TO BASELINE

To answer the first study question (*Are AEMP component assessment endpoints at impact sites changing from baseline conditions or reference ranges as a result of the Mine?*), sediment quality in the "after" period (i.e., 2024 and 2025) were compared to baseline years and Year 1 of Construction (2017, 2021, 2022, and 2023).

Particle Size and Total Organic Carbon

Generally, the observed particle size distribution at each site in 2025 was similar to distributions observed at the same sites in baseline years (Figure 4.3-1), with few exceptions of greater fine particles (silt and clay) at both impact and control sites. The mean proportion of silt and clay at Davidson Creek site DC-15 in 2025 (19.9% for silt and 4.44% for clay) was greater than observed in baseline years (7.94% for silt and 1.28% for clay).

Similar to the proportion of silt and clay, site DC-15 in Davidson Creek had greater TOC in 2025 (7.91%) than observed in the baseline or 2024 (3.41%; Figure 4.3-2). The 2025 TOC at sites in Creek 661 was similar to the baseline TOC. Regional control sites (705-05, 705-10, and FC-01) TOC measured in 2025 were similar or marginally greater than the observed baseline years (difference of 0.92 to 1.80%). Changes in TOC compared to baseline were typically related to observed changes in the proportions of fine sediments across sites (Figure 4.3-2 and Figure 4.3-1).

Metals

Before-after control-impact analyses were conducted for sediment quality parameters with SQG-Als: arsenic, cadmium, chromium, copper, iron, lead, manganese, mercury, molybdenum, nickel, selenium, silver, and zinc (Appendix B-4).

In Davidson Creek watershed, sediment arsenic, cadmium, copper, lead, silver, and zinc concentrations were significantly different ($p_{adjusted} < 0.05$) between the "before" and "after" periods compared to the difference in the control sites (i.e., a significant "class:period" interaction). The adjusted p was used to account for the multiple models used in the BACI analysis to assess before-after and control-impact, where each model used has a chance of significance set to 5% ($\alpha = 0.05$).

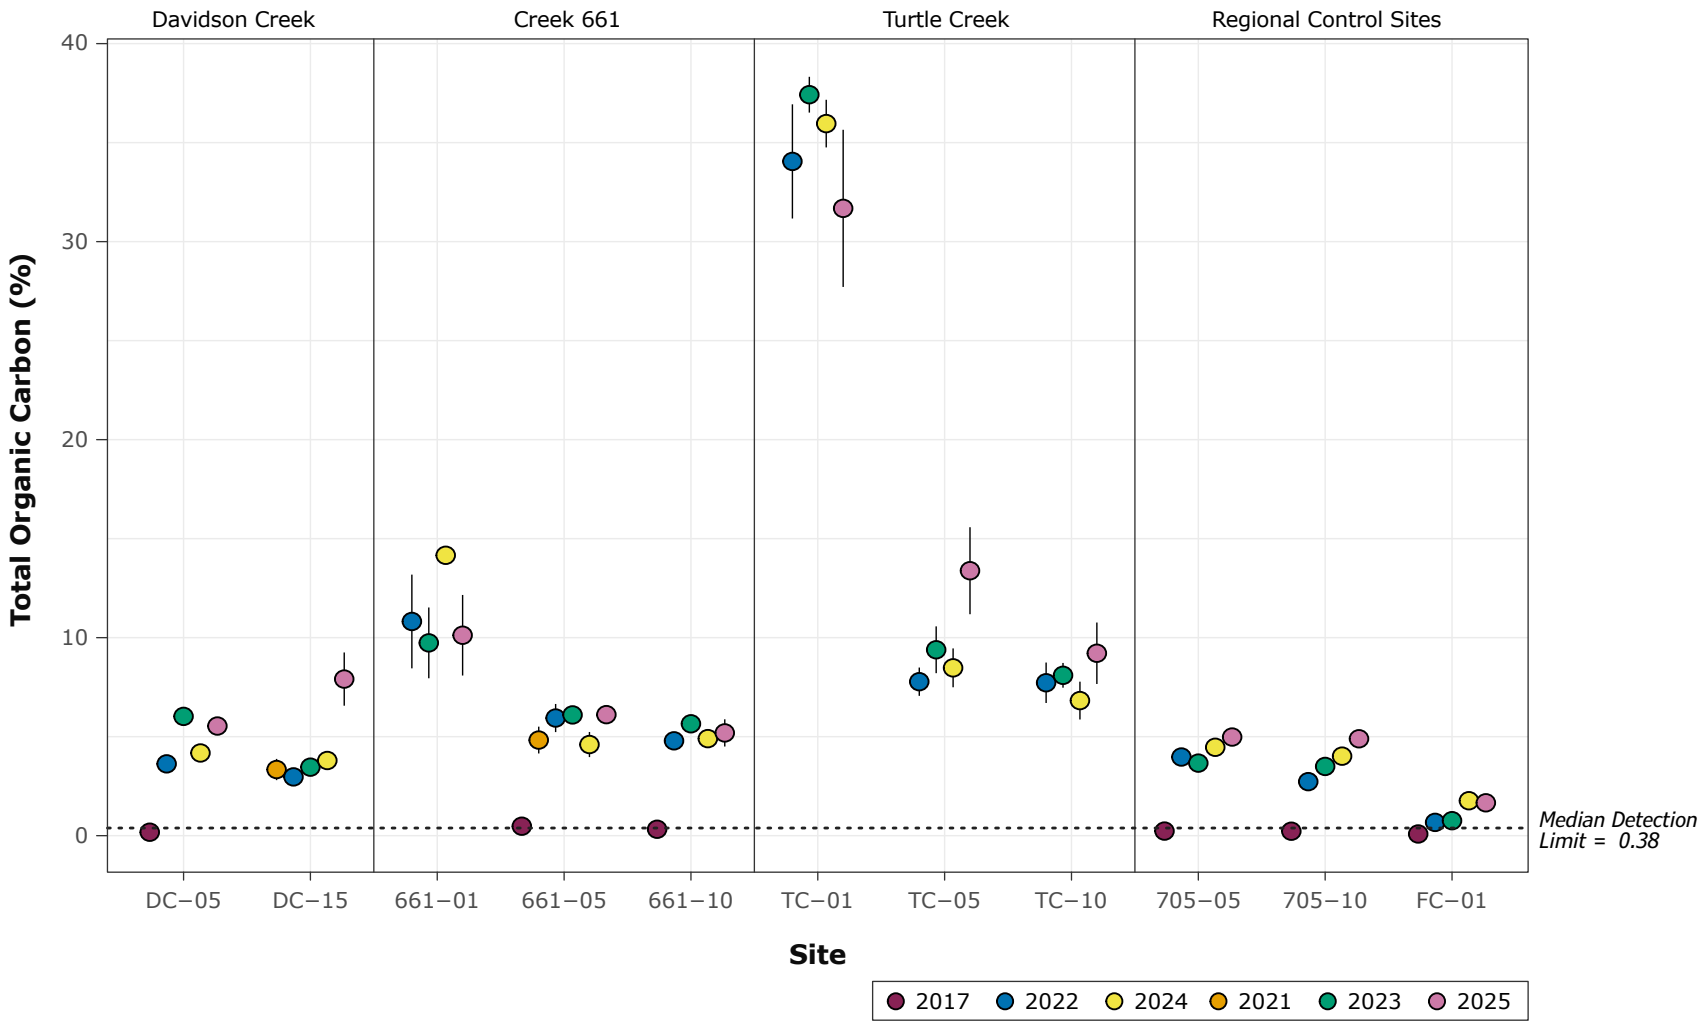
Note: Stacked bars represent the mean value of the replicates.

FIGURE 4.3-2 SEDIMENT ORGANIC CARBON CONCENTRATION, BASELINE AND CONSTRUCTION YEAR 1 (2017, 2021, AND 2022), CONSTRUCTION (2023 AND 2024), AND OPERATIONS (2025)



Note: Error bars represent the standard error of the mean.
Values below the detection limit were plotted as half the detection limit.

Significant results for parameters evaluated indicate that construction and operational activities since 2024 (i.e., the discharges to Davidson Creek from the TSFC-SCP, the March 2025 TSS release to Davidson Creek, and May and June 2025 clearing activities upstream of DC-05) may have affected sediment quality in the aquatic receiving environment. Forest fires can result in soil/sediment and associated adsorbed metals to be washed into streams (Rust et al. 2022) because of erosion and deposition of fine material. The water quality results suggest that effects of the wildfire (July 2023 and August 2024) resulted in an increase in total metals that likely contributed to the increase in sediment metals across sites (Section 2.2.4).

Graphical analysis confirms that at arsenic, cadmium, copper, lead, molybdenum, silver, and zinc sediment concentrations at DC-05 were greater in 2025 when compared to 2024 and baseline (Figures 4.3-3 to 4.3-9) and can be attributed to the Mine activities occurring in 2024 and early 2025. Concentrations were typically lower at DC-15 confirming that increases were related to the Mine activities.

In Creek 661 watershed, sediment cadmium, copper, lead, molybdenum, and zinc concentrations were significantly different between the "before" and "after" periods compared to the difference in the control sites. Graphical analysis suggests that changes in site 661-10 have been greater than observed at site 661-05 (Figure 4.3-4, Figure 4.3-5, Figure 4.3-6, Figure 4.3-7, and Figure 4.3-9). Site 661-10 is located on the Creek 661 mainstem downstream of the potentially impacted Creek 661 tributaries 146920 and 505659 (Figure 1.7-3). Thus, effects at site 661-10 may be related to the wildfires in addition to the ore stockpile dust event that occurred in Q1 of 2025.

4.3.2 STUDY QUESTION 3—COMPARISON TO SEDIMENT QUALITY GUIDELINES

To answer the third study question (*Are AEMP component assessment endpoints at impact sites changing to levels that may be associated with effects as a result of the Mine?*) stream sediment quality observed during 2025 were compared to SQG-ALs (Table 4.1-1). Guideline exceedances were identified for each group of samples (replicates), and the mean magnitude of exceedance (factor) was calculated for replicates that exceeded the guideline (Table 4.3-1).

The following metals exceeded the SQG-AL in one or more replicates samples collected in 2025: arsenic, cadmium, chromium, copper, iron, manganese, mercury, molybdenum, nickel, selenium, silver, and zinc. However, for mercury and molybdenum the mean sediment concentration (of the five replicates) at the site with the observed exceedance (661-01) did not exceed the guideline (BC lower guideline). Sites and parameters at which at least one replicate sample of sediment collected exceeded the BC upper guideline were DC-05 and DC-15 (arsenic, manganese), 661-01 (arsenic, iron, manganese), 661-05 (arsenic, manganese), 661-10 (arsenic, chromium, manganese, nickel, zinc), 705-05 (arsenic, chromium, manganese), 705-10 (manganese), and FC-01 (arsenic). The mean sediment concentration (of the five replicates) for arsenic at 661-05, chromium at 661-10 and 705-05, and nickel at 661-10 did not exceed the BC upper guideline.

Exceedances of SQG-ALs observed at impact sites in Davidson Creek and Creek 661 (i.e., DC-05, DC-15, 661-05, and 661-10) in 2025 have generally been observed at upstream control sites (i.e., 661-01) and regional control sites and exceedances were observed in all monitoring years indicating that sediments are naturally enriched in the Mine area (Table 4.3-2).

Notes:
Frequency represents the percentage of samples that were greater than the guideline concentration and factor (shown in brackets) represent the mean magnitude of observed exceedances.
Highlighted values indicate the mean sediment quality concentration did not exceed the guideline.
BC = British Columbia; CCME = Canadian Council of Ministers of the Environment
Refer to Table 4.2-2 for sediment quality guideline value.
Only parameters with guidelines exceedances in 2025 were included in the table.

TABLE 4.3-2 FREQUENCY AND MAGNITUDE OF EXCEEDANCE OF SEDIMENT QUALITY GUIDELINES BY WATERSHED AND SAMPLING PERIOD, 2017 TO 2025

Notes:
Frequency represents the percentage of samples that were greater than the guideline concentration and factor (shown in brackets) represent the mean magnitude of observed exceedances.
Highlighted values indicate the mean sediment quality concentration did not exceed the guideline.
BC = British Columbia; CCME = Canadian Council of Ministers of the Environment.
Refer to Table 4.2-2 for sediment quality guideline value.
Only parameters with guidelines exceedances were included in the table.

However, for many parameters SQG-AL exceedances at impact sites in Davidson Creek and Creek 661 in 2025 generally have greater frequency and magnitude than observed during the baseline period (Table 4.3-2). In Davidson Creek, sediment arsenic concentrations at DC-05 and DC-15 have consistently (100% frequency) exceeded the BC lower but the difference in the factor of exceedance in 2025 (3.6) was greater than construction years (2.15 to 2.39) and the baseline period (1.64). Higher sediment arsenic concentrations have resulted in a greater frequency (10% to 90%) of exceedance for the BC upper SQG-AL in construction and operation periods compared to no exceedances during the baseline period. Cadmium and zinc SQG-AL exceedances have a greater frequency (90%) and factor (1.68 and 1.56, respectively) in 2025 compared to the infrequent exceedances observed during the construction period (2023 and 2024, 20% to 40% frequency and 1.12 to 1.45 factor); baseline cadmium and zinc concentrations did not exceed SQG-ALs in Davidson Creek. Iron, manganese, and nickel sediment concentrations have a greater frequency of exceedance in the construction and operation periods compared to baseline. Although exceedances of SQG-ALs are also typical in regional control sites, the 2025 SQG-ALs exceedances observed in Davidson Creek were typically of greater frequency compared to exceedances observed in the regional control sites.

In Creek 661, sediment concentration exceedances of the SQG-Als at the impact sites were greater in frequency and magnitude during construction and operations, compared to the baseline period, for arsenic, cadmium, chromium, manganese, nickel, zinc (Table 4.3-2). Infrequent (less than 30%) iron and silver exceedances have been observed during construction and operations that did not exceed the SQG-AL during the baseline period. The upstream control site (661-01) consistently (100% frequency) exceeded the same SQG-ALs through all periods and the magnitude of the exceedance has increased compared to the baseline period.

4.3.3 SPECIAL STUDY—HYDROCARBONS

Analytical results for the stream sediment hydrocarbon study are provided in Appendix B-6 and assessment of the QA/QC results, including calculated RPDs of the field split samples are provided in Appendix B-7.

Baseline sediment PAH concentrations were analysed at sites DC-05 and DC-15 in Davidson Creek, sites 661-01, 661-05, and 661-10 in Creek 661, site TC-05 in Turtle Creek, and regional control site, 705-05. All measured sediment PAH concentrations were less than the DL (Appendix B-6), indicating naturally low concentrations of PAHs in the mine site area. The measured concentrations of benzo(g,h,i)perylene, benzo(k)fluoranthene, chrysene, fluoranthene, indeno (1,2,3,c,d) pyrene, naphthalene, pyrene, and total PAHs were less than the SQG-AL (Table 4.2-3). The DL for the following parameters were greater than the BC lower guideline/CCME ISQG but not the BC upper guideline/CCME PEL (Table 4.3-2):

- Acenaphthene;
- Acenaphthylene;
- Anthracene;
- benz(a)anthracene;
- benzo(a)pyrene;
- dibenz(a,h)anthracene;
- fluorene;
- methylnaphthalene, 2-; and
- phenanthrene.

4.4 SEDIMENT QUALITY RESPONSE FRAMEWORK

4.4.1 METHODS

Parameters included in the sediment quality response framework are metals with BC (BC WLRS 2025b) and CCME (CCME 2025c) SQG-ALs, in addition to TOC and particle size. The metals with SQG-ALs include arsenic, cadmium, chromium, copper, iron, lead, manganese, mercury, molybdenum, nickel, selenium, silver, and zinc (Table 4.2-2).

The evaluation of results against NPMs for sediment quality was based on near-field sites:

- Davidson Creek: DC-05, and DC-15
- Creek 661: 661-05 and 661-10.

Turtle Creek (TC-05) was not included in 2025 because the airstrip has not been constructed.

Sediment quality NPMs and management responses for each action level are provided in Table 5.2-3 of the AEMP Plan (ERM 2025b). The specific NPMs baseline concentrations (95th percentile) used for the sediment quality response framework are provided in Appendix B-5A (DC-05), Appendix B-5B (DC-15), Appendix B-5C (661-05), and Appendix B-5D (661-10).

4.4.2 RESULTS

Comparisons between 2025 sediment quality results for DC-05, DC-15, 661-05, and 661-10 were compared to the NPM conditions and are summarized in Figure 4.4-1.

To meet the action level "none" the 2025 mean sediment quality parameter value or concentration in stream sediments meet the following NPM conditions:

- **[Condition 1]** lower than the most conservative SQG-AL (BC WLRS 2025b; CCME 2025c; Table 4.2-2); or
- **[Condition 2]** lower than or equal to the 95th percentile baseline (2017 to 2023) concentration.

Sediment quality concentrations at the near-field sites meeting both conditions indicate that there is no requirement for a change to current mitigation measures. Evaluated parameters at Davidson Creek and Creek 661 sites met the conditions of the "none" action level with some exceptions (Figure 4.4-1).

For those parameters that did not meet all "none" NPMs, the conditions of the "low" NPM were evaluated. To meet the conditions of the "low" action level for sediment quality the mean sediment quality parameter value or concentration in stream sediments meets the following conditions:

- **[Condition 1]** lower than the most conservative SQG-AL (BC WLRS 2025b; CCME 2025c); or
- **[Condition 2]** greater than the 95th percentile baseline (2017 to 2023) concentration; and
- **[Condition 3]** changes in concentration are not statistically significant between near-field and control sites or compared to baseline conditions (BACI analysis).

FIGURE 4.4-1 EVALUATION OF SEDIMENT QUALITY NUMERIC PERFORMANCE METRIC CRITERIA AT DAVIDSON CREEK AND CREEK 661 NEAR-FIELD SITES, 2025

Davidson Creek	Numeric Performance Metrics					Action Level[4]

Silver	0%	40%	higher	lower	not significant	Low	None
Zinc	60%	100%	higher	higher	significant	High	High

Notes: "NG" indicates no guideline.
Shading indicates Numeric Performance Metric was met.
Guideline percentage represents the frequency of replicate exceedance.
[1] 2025 mean sediment concentration greater than than the lower (most conservative) sediment quality guideline for the protection of aquatic life (Table 4.3-1)
[2] 2025 mean sediment concentration was higher or lower than the baseline (2017, 2022, and 2023) 95th percentile concentration (Appendix B-5)
[3] 2025 results of the Before-After-Control-Impact (BACI) statistical analysis (Appendix B-4); a signficant result indicates that changes in concentration are significant between near-field and control sites or compared to baseline conditions. The parameters selected for BACI analyses were limited to parameters with sediment quality guidelines.
[4] Action levels are defined as Numeric Performance Metrics are met (Figure 1.8-2).

Action Levels *None Low Medium High*

The following sites and parameters met the conditions of the "low" NPMs:

- DC-05—chromium, iron, manganese, nickel, and selenium
- DC-15—percent clay, silt, and TOC, iron, manganese, mercury, nickel, and selenium
- 661-05—arsenic, chromium, manganese, mercury, nickel, and silver
- 661-10—arsenic, chromium, iron, manganese, and nickel

For those parameters that did not meet all "low" action level NPMs, the conditions of the "medium" action level were evaluated. To meet the "medium" action level for sediment quality the mean sediment quality parameter value or concentration in stream sediments meet the following NPM conditions:

- **[Condition 1]** lower than the most conservative SQG-AL (BC WLRS 2025b; CCME 2025c); or
- **[Condition 2]** greater than the 95th percentile baseline (2017 to 2023) concentration; and
- **[Condition 3]** changes in concentration are statistically significant between near-field and control sites or compared to baseline conditions (BACI analysis).

The following sites and parameters met the conditions of the "medium" NPMs:

- DC-05—copper and lead
- DC-15—silver
- 661-05—cadmium
- 661-10—copper and molybdenum

A significant BACI result indicates that the sediment concentrations are changing from baseline concentrations but are below levels of concern if the concentrations are lower than the most conservative SQG-AL. Therefore, the parameters meeting the "medium" have changed and from baseline likely as a result of the Mine activities in 2024 and 2025 (Davidson Creek sites), the ore stockpile dust event (Creek 661 sites), and wildfires (Davidson Creek and Creek 661 sites) but are not at levels that indicate the potential for adverse effects to aquatic life (i.e., SQG-AL are not exceeded).

For those parameters that did not meet all "medium" action level NPMs, the conditions of the "high" action level were evaluated. At the "high" action level both Condition 2 (greater than baseline) and Condition 3 (significant "class:period" interaction for the BACI analysis) are met in addition to an exceedance of the most BC lower SQG-AL. Thus, the following sites and parameters met the conditions of the "high" NPMs:

1. DC-05 and DC-15—arsenic, cadmium, and zinc
2. 661-05—zinc
3. 661-10—cadmium and zinc

The sediment quality response framework lists the following management responses at a "high" action level:

- Investigate to confirm root cause of changes in concentrations and implement new mitigation measures or further adjust existing mitigation measures to address root cause;

- Increase monitoring frequency to annual if frequency is less than once per year;
- Implement a sediment sampling program to define the magnitude, spatial extent, and reversibility of the effect;
- Implement a sediment toxicity study as developed at the "medium" action level; and
- Implement monitoring to assess effectiveness of mitigation options.

The elevated arsenic, cadmium, and zinc sediment concentrations at DC-05 and DC-15 are attributed to construction and operational activities since 2024 (i.e., the discharges to Davidson Creek from the TSFC-SCP, the March 2025 TSS release to Davidson Creek, and May and June 2025 tree clearing activities upstream of DC-05). Sediment quality analysis was completed on the fine-grained (less than 63 µm) because the fine fraction is expected to support a large part of the benthic community and is recommended by the provincial technical guidance for sampling (BC MOE 2026). However, the BC SQG-ALs are derived using statistical analysis of concurrent sediment chemistry and toxicity test dataset that is based on bulk concentrations (i.e., samples are not pre-sieved to less than 63 µm prior to laboratory analysis). The DC-05 and DC-15 magnitude of exceedance of the arsenic, cadmium, and zinc BC lower SQG-AL was less than 5 times the guideline and the magnitude of the arsenic BC upper SQG-AL was less than 2 times the guideline at those sites (Table 4.3-1). Thus, likelihood of adverse effects to aquatic life is low which was supported by no significant alterations of benthic communities (Section 6.3-1) or changes in tissue metal concentrations (Section 6.3-2). Adverse effects are defined based on the parameter concentrations where sediment metal concentrations are at a level where aquatic life is potentially unable to survive, grow, or reproduce. Thus, given the low magnitude of exceedances a sediment toxicity testing sampling program was not initiated. Runoff management and erosion and sediment control mitigations in response to turbid water entering Davidson Creek (either as unauthorized discharges or following exceedances of permit limits) will continue to mitigate future "high" action level exceedances.

The elevated cadmium and zinc sediment concentrations at Creek 661 sites are attributed to the wildfires in addition to the ore stockpile dust event that occurred in Q1 of 2025. The magnitude of the cadmium and zinc BC lower SQG-AL exceedance on the fine fraction sediments was less than 3 times the guideline and less than 2 times the zinc BC upper SQG-AL (Table 4.3-1). Thus, the likelihood of adverse effects to aquatic life are low. Sediment was also collected at the site immediately downstream of the ore stockpile dust event, 661-04. The site 661-04 mean sediment concentrations and comparison to baseline and SQG-AL also suggest there were effects of the dust event that likely did not result in adverse effects to aquatic life (Table 4.4-1).

BW Gold investigated wind fencing to mitigate dusting from the ore stockpile drop points, but this option was deemed not feasible as the design criteria did not prove to be effective for dust management (Environmental Life of Mine Committee [ELoMC] meeting minutes, August 28th, 2025). Following notification from BC EAO in May 2025, BW Gold implemented mitigation measures to minimize the dust event from the ore stockpile (i.e., operational spray bars installed at the primary crusher, the conveyor, and the ore stockpile drop points; the secondary crusher is enclosed, and therefore no spray bars were needed). In September 2025 BW Gold announced it would be installing a cover on its coarse ore stockpile.

TABLE 4.4-1 MEAN SEDIMENT CONCENTRATIONS AT SITE 661-04

Parameter	Guideline		Unit	Baseline (2022)		Construction (2023)		Operations (2025)

Notes:
Shaded means indicate exceedance of the BC Lower Sediment Quality Guideline (BC WLRS 2025b).
Shaded and bolded means indicate exceedance of the BC Upper Sediment Quality Guideline (BC WLRS 2025b).

Dusting plumes generated from road use are documented in the visual dust observation log. BW Gold is actively implementing dust mitigation measures (in accordance with the Air Quality and Fugitive Dust Management Plan) in response to dust observations; however, opportunities remain to improve the consistency of mitigation documentation in the observation log.

4.5 SUMMARY AND RECOMMENDATIONS

Davidson Creek impact site sediments in 2025 were typically characterized as higher composition of fine particles (i.e., clay and silt) and TOC, arsenic, cadmium, copper, lead, molybdenum, silver, and zinc concentrations when compared to the baseline and construction years. Higher metal concentrations in the sediments of Davidson Creek impact sites have resulted in more frequent and/or high magnitude exceedances of arsenic, cadmium, iron, manganese, nickel, and zinc SQG-Als than observed in baseline years and compared to the regional control sites. The water quality results suggest that effects of the wildfire (July 2023) resulted in an increase in total metals that likely contributed to the increase in sediment metals across sites (Section 2.2.4). However, the magnitude of change in arsenic, cadmium, and zinc sediment concentrations in Davidson Creek are partly attributed to construction and operational activities since 2024 (i.e., the March 2025 release of TSS laden water to Davidson Creek, and May and June 2025 tree clearing activities upstream of DC-05). Concentrations were typically lower at DC-15 when compared DC-05 (immediately downstream of mine activities) confirming that increases were related to the Mine activities and the 2023 wildfire.

In Creek 661 watershed, sediment cadmium, copper, lead, molybdenum, and zinc concentrations were higher in 2025 compared to baseline and construction years. In Creek 661, SQG-AL exceedances at the impact sites were greater in frequency and magnitude during construction and operations, compared to the baseline period, for arsenic, cadmium, chromium, manganese, nickel, zinc. Similar to Davidson Creek the water quality results suggest that effects of the wildfire resulted in an increase in sediment metals (Section 2.2.4). However, the elevated cadmium and zinc sediment concentrations at Creek 661 sites are also partly attributed to the ore stockpile dust event that occurred in Q1 of 2025. Changes in site 661-10 have been greater than observed at site 661-05 which may be related to the wildfires impact on tributaries 146920 and 505659.

Although sediment metal concentrations were greater than SQG-AL in 2025, the likelihood of adverse effects to aquatic life is low based on the overall magnitude of exceedance remaining low (i.e., less than 5 times the guideline) that was confirmed with the observation of no significant alterations to the benthic communities and tissue metal concentrations in 2025 (Section 6.3-2).

Baseline sediment PAH concentrations were analysed at sites DC-05 and DC-15 in Davidson Creek, sites 661-01, 661-05, and 661-10 in Creek 661, site TC-05 in Turtle Creek, and regional control site, 705-05. All measured sediment PAH concentrations were less than the DL, indicating naturally low concentrations of PAHs in the Mine area.

Continued erosion and sediment control mitigations and dust mitigations implemented or planned to be implemented as a result of the dust event will continue to be completed through the Operations period. No additional sampling or analyses other than that described in the AEMP Plan, Version 4.0 (ERM 2025b) is recommended.

5. AQUATIC PRIMARY PRODUCERS

5.1 MEASUREMENT ASSESSMENT ENDPOINTS

Periphyton (attached algae, fungi, bacteria, and associated detritus, also referred to as biofilm; BC MOE 2016a) was selected for the aquatic plant monitoring required by EAC #M19-01 Condition 30(g) instead of macrophytes as an indicator of water quality and primary productivity. Aquatic macrophytes (aquatic plants that are often rooted or with roots that have distinct component structures large enough to be visible to the naked eye; BC MOE 2016a) are typically more abundant in lentic environments and, as indicated during baseline monitoring completed in 2011 and 2012, there was minimal macrophyte coverage at AEMP sampling sites (AMEC 2013a).

The selected measurement endpoints for periphyton analysis are focused on metrics associated with the primary producer (plant) component of periphyton. Periphyton biomass (as chlorophyll *a*) was assessed to determine the Mine-related effects on aquatic primary producers (Table 5.1-1). Assessment endpoints include BACI analysis and comparison to BC guidelines for the protection of freshwater aquatic life.

TABLE 5.1-1 MEASUREMENT AND ASSESSMENT ENDPOINTS FOR AQUATIC PRIMARY PRODUCERS

Measurement Endpoint	Assessment Endpoint
Biomass (as chlorophyll *a*)	• Graphical comparison to baseline data • Before-after-control-impact analysis • Comparison to BC water quality guideline for the protection of aquatic life (BC WLRS 2025b)
Taxonomy (community composition)	• Comparison to baseline[1]

[1] Diversity indices genus richness and the Simpson's Diversity Index are assessed.

Periphyton community composition (taxonomy) was completed to aid in the understanding of changes in periphyton biomass. The assessment endpoint for community composition is the comparison to baseline community composition.

5.2 SAMPLING SITES AND METHODS

As defined in the AEMP Plan (ERM 2025b), primary producers (periphyton) samples were collected annually at sites downstream from the Mine and control sites, as indicated in Table 1.7-2. One site on Turtle Creek, TC-05, was not sampled for periphyton due to a lack of appropriate substrate and conditions.

5.2.1 FIELD METHODS

Periphyton biomass and taxonomy sampling was conducted according to *the British Columbia Field Sampling Manual Part C* (BC MWLAP 2013). Sampling was completed between September 9 and September 17, 2025, concurrent with sediment quality and benthic invertebrate sampling.

Periphyton biomass (as chlorophyll *a*) and community composition samples were collected at each of the stream sites. Taxonomy samples consisted of three replicates collected independently from the five replicate biomass samples in accordance with BC ENV guidance (BC ENV 2023b). Three pooled templates from an individual rock to form a replicate (surface area = 58.8 cm^2) were completed. Each replicate was collected using a modified toothbrush to scrape the periphyton, a syringe to extract loosened periphyton, and a wash bottle for repeat rinsing of the area. Samples were stored with ice packs in coolers until they could be processed back at camp later that day.

The biomass samples were prepared by gently filtering samples through a 0.45 µm cellulose filter using a hand pump and filtering apparatus. Filters were folded in half using forceps, placed in an opaque tube to prevent light penetration, and kept frozen until they were analyzed by ALS.

The taxonomy samples were preserved with Lugol's iodine solution and shipped to Biologica Environmental Services Ltd. (Biologica) in Victoria, BC for enumeration, identification, and to continue the reference collection.

5.2.2 LABORATORY METHODS

The analysis of chlorophyll *a* concentration as periphyton biomass was conducted by ALS in accordance with the *BC Environmental Laboratory Manual* (BC ENV 2023b).

The taxonomic analysis consisted of numeration and identification completed using the Utermöhl procedure. Subsamples were diluted appropriately to a standard volume, homogenized, and allowed to gravity settle for at least 12h in settling chambers. Transects were counted at 400x magnification until 300 algal units, defined as a single cell, colony, or filament, were enumerated or three parallel transects were examined. Diatoms were enumerated at the same time as other (soft) algae, and the laboratory consulted the historical digital reference collection to ensure taxonomic identifications were consistent. The mean number of cells per unit (= 1 for single cells, >1 for all other algal forms) were estimated for all taxa and used to calculate total densities. Only "viable" cells (those that appeared to be alive at the time of collection) were identified and enumerated. Algae were identified to genus, where possible, following the most up-to-date taxonomic references and collaborations with international and local algal taxonomic experts. Species-level identifications were only given to identifiable taxa for which there are reliable taxonomic references available that encompass the species-level morphological diversity in North America.

5.2.3 QUALITY ASSURANCE/QUALITY CONTROL

The 2025 periphyton field QA/QC program included five replicates for biomass and three replicates for periphyton taxonomy. Chain of custody forms were used for all samples.

The laboratory QA/QC program for biomass (chlorophyll *a*) included method blanks and laboratory control samples and analyses were conducted by a CALA-certified laboratory.

For periphyton taxonomy, Biologica followed their own internal QA/QC procedures that included having a minimum of 10% of samples analyzed by two separate taxonomists to ensure taxonomic accuracy and the reproducibility of sample processing methods (Findlay and Kling 2023). Two different taxonomists subsampled, identified, and enumerated periphyton from the same sample using identical methods.

The results were compared by calculating the percent similarity:

$$Percent\ similarity = 100 - 0.5 \sum |a - b|$$

where *a* was the percentage of individuals of a taxon in sample A, and *b* was the percentage of the same taxon in sample B. The percent similarity between the samples was an indication of subsampling and taxonomic precision. A percent similarity of ≥ 80% is required by Biologica internal procedures. If 80% similarity is not met, the reasons for the discrepancies between analysts are discussed and necessary adjustments made to the dataset.

5.2.4 DATA ANALYSIS

Periphyton samples were also collected in 2011, 2012; however, only the 2017, 2022, and 2023 biomass (chlorophyll *a*) and the 2017, 2021, 2022, and 2023 (taxonomy) observations were utilized as the baseline years because of variability in field collection and laboratory methods in earlier sampling programs (ERM 2023).

5.2.4.1 STUDY QUESTION 1—PERIPHYTON BIOMASS COMPARISON TO BASELINE

To answer the first study question (*Are AEMP component assessment endpoints at impact sites changing from baseline conditions or reference ranges as a result of the Mine?*), periphyton biomass in the "after" period (i.e., 2024 and 2025) were compared to baseline years and Year 1 of Construction (2017, 2022, and 2023). Year 1 of Construction (2023) was added to the "before" period because it was concluded that there were limited construction activities and no surface water discharge in 2023 (ERM 2025b).

Periphyton biomass (as µg chlorophyll *a*/cm^2) was calculated for each replicate sample, and a mean and standard error were calculated for each stream site.

A BACI statistical analysis was performed on periphyton biomass for the Davidson Creek and Creek 661 watersheds. There were no construction activities at Turtle Creek sites TC-01, TC-05, and TC-10 (i.e., no airstrip-related construction work), therefore these sites were excluded from analyses. The BACI analysis introduces a class effect to a mixed model ANOVA, which is based on the classification of a site as an impact or a control site. The "control" sites included the regional control sites FC-01, 705-05, and 705-10 for both watersheds, and 661-01 for sites in the Creek 661 watershed. The "impact" sites were DC-05 and DC-15 in the Davidson Creek watershed, and 661-05, and 661-10 in the Creek 661 watershed. A random effect of year to account for variability in periphyton biomass was also included. The "before" period was the data collected in baseline (2017 and 2022) and Year 1 of Construction (2023). The "after" period was data collected in 2024 and 2025. The "control" sites included the regional control sites FC-01, 705-05, and 705-10 for all impact sites, and 661-01 for sites in the Creek 661 watershed. The "impact" sites were DC-05 and DC-15 in the Davidson Creek watershed, and 661-05, and 661-10 in the Creek 661 watershed.

The BACI analyses tested the hypothesis that if mine activities affected periphyton biomass, the expectation would be a significant change in periphyton biomass at near-field sites in comparison with baseline concentrations not observed at control sites. If both impact and control sites experienced a parallel change over time, then it would be likely a change over a larger spatial scale affected all control and impact sites, and it is unlikely that construction activities affected periphyton biomass concentrations.

Analysis was performed using the most recent R statistical computing package (R Core Team 2025). Data transformations (e.g., log transformation) were completed if determined to be appropriate (e.g., to achieve random distribution of residuals).

The interaction between the period ("before" or "after") and class (impact or control) effects would indicate whether any before-after change in the mean chlorophyll *a* concentration occurred in the impact site also occurred in the control site(s). The overall site (control versus impact) and period ("before" versus "after") interaction significance (p-value less than significance level (α) of 0.05) was assessed using an F test. To reduce the number of false positives (Type I error) due to the large number of statistical tests conducted, multiple test correction was applied.

5.2.4.2 STUDY QUESTION 3—PERIPHYTON BIOMASS COMPARISON TO WATER QUALITY GUIDELINES

To answer the third study question (*Are AEMP component assessment endpoints at impact sites changing to levels that may be associated with effects as a result of the Mine?*) the 2025 mean periphyton biomass for each of the monitored sites was compared to the BC WQG-AL (10 µg chlorophyll *a*/cm^2; BC WLRS 2025b).

5.2.4.3 STUDY QUESTION 1—PERIPHYTON COMMUNITY COMPOSITION METRICS COMPARISON TO BASELINE RANGES

The periphyton mean total density and community composition of major taxonomic groups were calculated and presented graphically for each sampling location. To answer the first study question (*Are AEMP component assessment endpoints at impact sites changing from baseline conditions or reference ranges as a result of the Mine?*), mean diversity metrics (genus richness and Simpson's Diversity Index) were compared between samples collected in the "after" period (i.e., 2024 and 2025) to baseline years and Year 1 of Construction (2017, 2021, 2022, and 2023). Year 1 of Construction (2023) was added to the "before" period because it was concluded that there were limited construction activities and no surface water discharge in 2023 (ERM 2025b).

Periphyton taxonomic data included all organisms identified in the periphyton counts, except those that were too damaged to reliably identify or were not identified to a sufficient taxonomic resolution (i.e. Phylum). Mean total density and community composition of major taxonomic groups were calculated and presented graphically for each site.

Diversity metrics were calculated at the genus level. If periphyton were identified to the species level, they were grouped into their respective genera designation. If an organism was not identified to the genus level, and no other organism was identified within that group (i.e., order, family, etc.), it was assumed that there was one genus in that group of organisms. All other specimens were otherwise excluded from the diversity calculations.

Diversity analyses include the calculation of genus richness (G) and the Simpson's Diversity Index (D) according to:

$$G = \text{the total number of genera present per sample; } D = 1 - \sum_{i=1}^{S} (p_i)^2$$

where: S = the number of taxa in the replicate, and
p_i = the proportion of the i^{th} taxon in the replicate.

The relative abundance of each genera was calculated as n_i/N, where n_i is the number of individuals in genera i, and N is the total number of all individuals. Simpson's Diversity Index ranges from 0 to 1, where 0 is no diversity (homogenous community) and 1 represents high, theoretically infinite, diversity.

Richness was based on presence/absence of a taxa, with all taxa identified to genus included in richness calculations (i.e., taxa with unit-length measurements); however, taxa with different counting methods (e.g., counting colonies as individuals) were excluded from the Simpson's diversity calculations. Simpson's diversity can range from 0 (lowest diversity) to 1 (maximum diversity). The use of Simpson's diversity index accounts for both the number of taxa present and the relative abundance of organisms from each taxa (evenness).

5.3 RESULTS AND DISCUSSION

The 2025 periphyton biomass and community taxonomy laboratory results are provided in Appendices C-1 and C-2, respectively. Assessment of the QA/QC results are provided in Appendix C-3. Calculated periphyton biomass and community metrics (density, richness, diversity) summary statistics for 2025 are provided in Appendix C-4. Appendix C-5 provides biomass BACI analysis results for Davidson Creek and Creek 661.

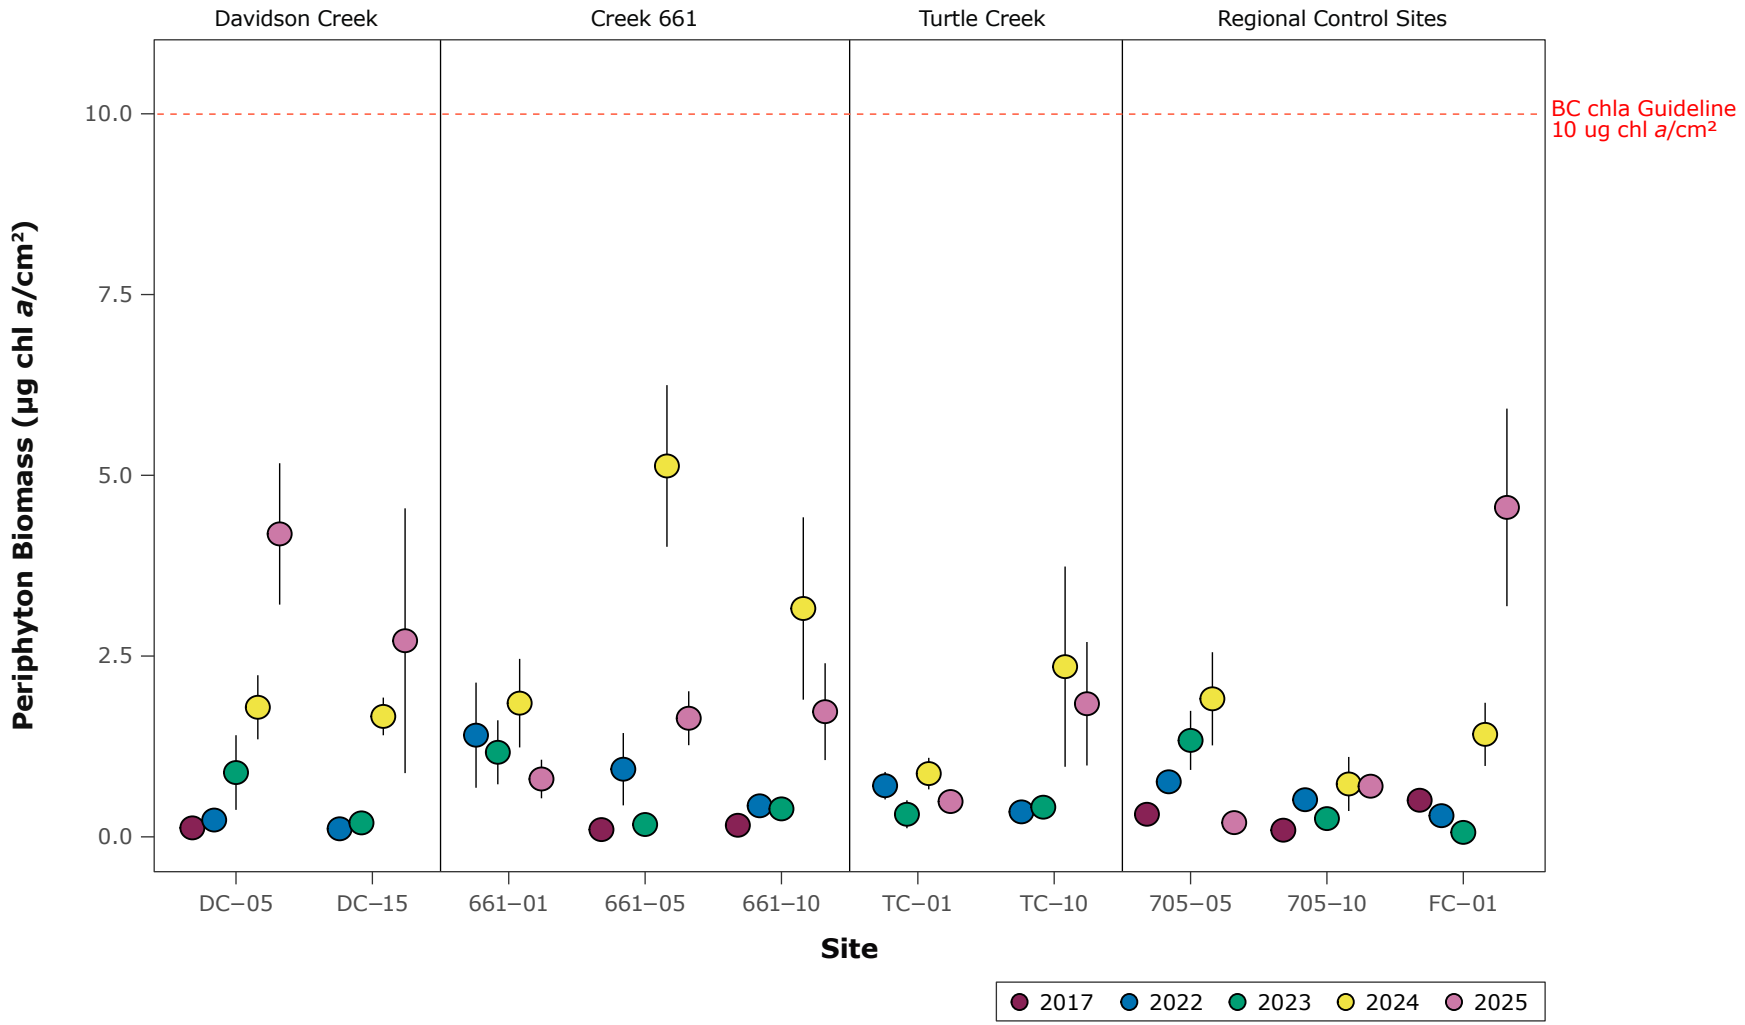
Periphyton parameter results for Turtle Creek sites are plotted on the figures and comparison to guideline results are provided, however no effects are anticipated because the airstrip has not been constructed (and not discussed further). A general characterization of periphyton biomass and community in Turtle Creek are provided in Appendix C-6.

5.3.1 STUDY QUESTION 1—PERIPHYTON BIOMASS COMPARISON TO BASELINE

Statistical analysis indicates that periphyton biomass in Davidson Creek and Creek 661 impact sites have increased relative to baseline biomass in each watershed (Figure 5.3-1); the results of BACI analysis indicated that there were significant differences between the "before" and "after" period at impact sites in Davidson Creek and Creek 661 ($p_{adjusted} < 0.05$) compared to the "before" and "after" period at their applicable control sites (Appendix C-5). The adjusted p was used to account for the multiple models used in the BACI analysis to assess before-after and control-impact, where each model used have a chance of significance set to 5% ($\alpha = 0.05$).

Mean periphyton biomass at sites in Davidson Creek have increased compared to the baseline. In 2025, mean periphyton biomass was 10 times greater than the mean baseline at site DC-05 and 18 times greater at site DC-15. A similar trend has been observed at regional control site FC-01 where 2025 mean biomass was 16 times greater than the comparable baseline mean. Similarly in Creek 661, periphyton biomass has been greater than the baseline range since 2024 at sites 661-05 and 661-10. Mean periphyton biomass at 661-05 and 661-10 was elevated relative to the baseline range in 2024 (13% and 10%, respectively) and lower in 2025 but remained greater than the baseline (4% and 5%, respectively). Periphyton biomass at the upstream control site, 661-01, has remained relatively stable through the monitoring years.

FIGURE 5.3-1 PERIPHYTON BIOMASS (AS CHLOROPHYLL *a*), BASELINE AND CONSTRUCTION YEAR 1 (2017, 2021, AND 2022), CONSTRUCTION (2023 AND 2024), AND OPERATIONS (2025)



Note: Error bars represent the standard error of the mean.

Graphical and statistical analysis, indicate that periphyton biomass has increased in the "after' period at impact sites in Davidson Creek and Creek 661 (Figure 5.3-1 and Appendix C-5). This suggests that 2024 and 2025 mine activities may have affected periphyton biomass in the downstream aquatic environments of Davidson Creek and Creek 661. A similar trend through the monitoring period was not observed in the Creek 661 upstream control site. However, a similar trend was observed at regional control sites 705-05 in 2024 and FC-01 in 2024 and 2025, which suggests some regional drivers of periphyton biomass that may have contributed to the observed increase.

Freshwater algae tend to be phosphorus limited and will respond to phosphorus enrichment by increases in biomass (Wetzel 2001). Total phosphorus at Davidson Creek were lower in 2025 when compared to 2024 but greater when compared to baseline (Figure A.7-11; Section 2.3.1). Total phosphorus at sites 661-05 and 661-10 were greater in 2024 and 2025 when compared to baseline years (Figure A.7-11; Section 2.3-1). Another limiting resource (e.g., light) was likely the driver for the observed increase in biomass. Sampling in 2024 and 2025 also took place later in September (between September 14 and 19, 2024 and between September 9 and 17, 2025) than in previous years (between September 4 and 12 in 2022 and 2023), therefore light conditions were likely different and periphyton may have had longer to grow, resulting in higher biomass in 2024 and 2025 compared to baseline and 2023.

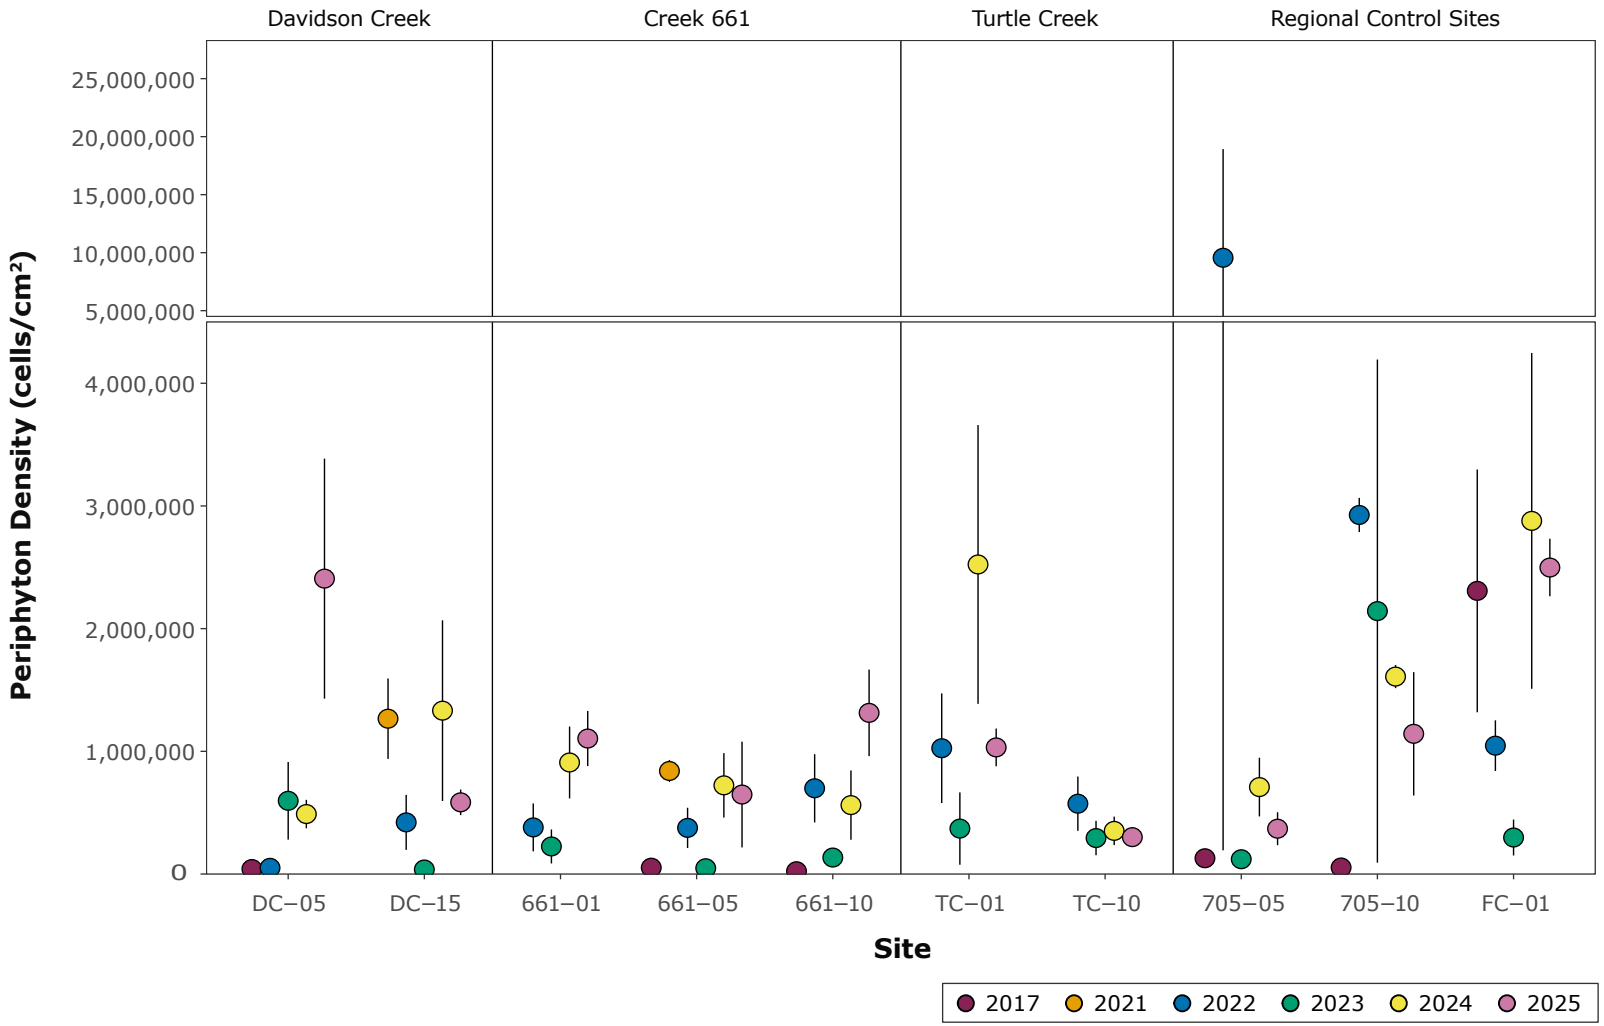
5.3.2 STUDY QUESTION 3—PERIPHYTON BIOMASS COMPARISON TO WATER QUALITY GUIDELINES

All periphyton chlorophyll *a* concentrations in 2025 were less than the chlorophyll *a* BC WQG-AL (10 µg/cm^2; BC WLRS 2025a). Periphyton biomass (as chlorophyll *a*) has consistently been below the BC WQG-AL at all sites for all monitored years including Operations (Figure 5.3-1). Therefore, nutrient eutrophication is not present at the monitored impact and control sites.

5.3.3 STUDY QUESTION 1—PERIPHYTON COMMUNITY COMPOSITION METRICS COMPARISON TO BASELINE RANGES

In Davidson Creek, 2025 periphyton density was greater at site DC-05 when compared to baseline years and construction (Figure 5.3-2). Periphyton density at DC-15 in 2025 was within the range of observed baseline densities. In Creek 661, the 2025 periphyton density was within the range of densities at site 661-05 during baseline and 661-10 was greater than baseline and construction period observations. At site 661-01, the 2025 densities were similar to 2024 (Construction Year 2) and greater than observed during baseline years. In general, phytoplankton density has been variable within impact and control sites and across years. Some annual variation in density may be related to the way the taxonomic laboratory defines a counting unit, which can be individual cells or colonies of cells (e.g. filamentous cyanobacteria). During taxonomic enumeration, colonies of cells are not distinguished by a prescribed number of cells within a colony or filament but rather based on qualitative observation of one grouping. Differences in counting units are magnified when the estimated count for the entire sample is estimated for the entire sample volume and enumeration area of a subsample. The taxonomic laboratory was the same in 2017, 2022, and 2023 (EcoAnalysts), but different in 2021 and 2024 (Biologica).

FIGURE 5.3-2 PERIPHYTON DENSITY, BASELINE AND CONSTRUCTION YEAR 1 (2017, 2021, AND 2022), CONSTRUCTION (2023 AND 2024), AND OPERATIONS (2025)



Note: Error bars represent the standard error of the mean.

The periphyton community composition in 2025 was dominated by blue-green algae (54 to 96%), with diatoms, or red algae at a few sites, largely contributing to the remaining relative proportions, and generally observed in the baseline period (Figure 5.3-3). The relative proportions of the periphyton community at site DC-05 in Davidson Creek in 2025 consisted of a greater proportion of diatoms (46%) compared to baseline years (7% to 16%), as a result of lower blue-green algae dominance (54% compared to 78% to 93%). At Creek 661 site 661-05, the periphyton community consisted of a greater proportion of blue-green algae (91%) compared to baseline years (30 to 87%), as a result of lower diatom proportions (5% compared to 10 to 56%).

Mean periphyton community richness in 2025 at the Davidson Creek and Creek 661 sites were within baseline ranges (10 to 22 species per sample; Figure 5.3–4). Mean periphyton diversity in 2025 was within the baseline ranges for Davidson Creek sites (0.41 to 0.69) but were approximately 25% lower than baseline ranges for the Creek 661 sites (Figure 5.3-5). Similar periphyton community richness but lower diversity in the Creek 661 sites is a result of the periphyton communities both being highly dominated (greater than 81% of the community composition) by two genera of blue-green algae. Blue-green algae Chamaesiphon represented 53% of the 661-05 community and 75% in 661-10 followed by Glaucospira in 661-05 (28%) and Heteroleibeinia in 661-10 (12%).

5.4 PERIPHYTON AND NUTRIENT RESPONSE FRAMEWORK

5.4.1 METHODS

Periphyton assessment endpoints included in the periphyton response framework are based on periphyton biomass as chlorophyll *a*. Total ammonia-N, nitrate-N, nitrite-N, and total phosphorus (as required by EMA Permit PE 110652 Condition 4.6.3[d]) are also included in the response framework.

As described for water quality (Section 2.4) and sediment quality (Section 4.4), spatially, the evaluation of chlorophyll *a* and nutrient monitoring results against NPMs was at near-field sites only. Any effects of the Mine on aquatic biota are likely to be most apparent at the near-field sites, including:

- Davidson Creek: DC-05 and DC-15; and
- Creek 661: 661-05 and 661-10.

Turtle Creek (TC-05) was not included because the airstrip has not been constructed.

Periphyton and nutrient NPMs and management responses for each action level are provided in Table 5.2-4 of the AEMP Plan (ERM 2025b). The specific NPMs baseline concentrations (95th percentile) used for the periphyton and nutrient response framework are provided in Appendix C-7.

Immature, damaged and unidentified individuals were excluded from all analyses except density calculations.

5.4.2 RESULTS

To meet the "none" NPM for aquatic primary producers the mean biomass (chlorophyll *a*) concentration in DC-05, DC-15, 661-05, and 661-10 must meet the following conditions:

- **[Condition 1]** lower than the chlorophyll *a* WQG-AL (BC WLRS 2025a; 10 µg/cm^2); or
- **[Condition 2]** lower than or equal to the 95th percentile baseline concentration.

Exceedance of the chlorophyll *a* WQG-AL (Condition 1) was not observed for any of the near-field sites in 2025 (Figure 5.3-1). However, Condition 2 was not met at all sites (Appendix C-7A). Thus, all four sites are brought forward for assessment of the "low" NPM conditions.

To meet the "low" NPM for aquatic primary producers the mean annual measured biomass (chlorophyll *a*) concentrations must meet the following conditions:

- **[Condition 1]** lower than the chlorophyll *a* WQG-AL (BC ENV 2024b; 10 µg/cm^2); and
- **[Condition 2]** greater than the 95th percentile baseline concentration of chlorophyll *a*; and
- **[Condition 3]** changes in chlorophyll *a* concentration are not statistically significant between near-field and control sites or compared to baseline conditions (BACI analysis)

Both Condition 1 and Condition 2 were met and the results of the BACI analysis, indicated that chlorophyll *a* concentrations at impact sites were significantly different (Davidson Creek $p_{adjusted}$ = 0.003; Creek 661 $p_{adjusted}$ = 0.0011) "before" and "after" when compared to control sites. Therefore, the conditions of the "medium" NPM for aquatic primary producers were met indicating chlorophyll *a* concentrations are changing from baseline concentrations but are below levels of concern (a "medium" action level).

For the nitrogen nutrient water quality parameters (total ammonia-N, nitrate-N, and nitrite-N), to meet the "none" NPM they must meet the same Condition 1 or Condition 2 as indicated in the water quality response framework (see Section 2.4.2). Total phosphorus must meet the following two conditions:

- **[Condition 1]** the mean monthly concentration is lower than the lower of the monthly mean total phosphorus + 50% or the upper limit of the baseline tropic range for the same month (Appendix C-7b); or
- **[Condition 2]** less than or equal to the 95th percentile of the predicted concentration (base case) in the same month.

Total ammonia-N, nitrate-N, and nitrite-N were not greater than the predicted concentration in any month at sites DC-05, DC-15, 661-05, thus the "none" action level is met (Figure 5.4-1). Total ammonia-N was greater than predicted and baseline in August and September at site 661-10. A BACI analysis was not completed however graphical analysis indicated that greater concentrations were observed in 2025 when compared to baseline years (Section 2.3.1) therefore, a "medium" action level was determined for total ammonia at 661-10. Nitrate-N, and nitrite-N were not greater than the predicted concentration in any month at site 661-10, thus the "none" action level is met. Nitrogen parameters did not exceed WQG-AL at any of the sites (Figure 5.4-1).

[2] Months indicate the "after" period monthly average was higher than the 95th percentile of the predicted concentration (base case) for the same month (Appendix A-14).
[3] Months indicates the "after" period monthly average was greater than the baseline benchmark (Appendix C-6c).
[4] Results of the Before-After-Control-Impact (BACI) statistical analysis; not completed if parameters had more than 70% of the values in the dataset for the parameter are below analytical detection limit or if monthly concentrations were not greater than the 95th percentile baseline concentration plus 20% for two or more consecutive months.
[5] Action levels are defined as Numeric Performance Metrics are met (Figure 1.8-1).

Action Levels *None Low Medium High*

ERM

CLIENT: BW Gold LTD.
GRAPHICS NUMBER: BWG-26ERM-013

Total phosphorus concentrations in Davidson Creek were not greater than the predicted concentration for two or more consecutive months. Thus, the "none" action level for total phosphorus is met for Davidson Creek sites (DC-05 and DC-15). In Creek 661, all months were greater than the predicted concentration for both site 661-05 and 661-10 but not greater than the baseline NPM in two consecutive months for 661-05. At site 661-10, August and September were greater than the baseline NPM and the BACI indicated a significant difference between the "before" and "after" period when compared to the control sites thus, a "high" action level is indicated for total phosphorus at 661-10. However, the August and September monthly average at 661-10 compared to the baseline NPM for total phosphorus includes relatively elevated concentrations observed in 2025 which did not persist (i.e., the total phosphorus concentrations observed in October to December 2025 were similar to observed baseline concentrations; Figure A7-15b). There was no indication of higher total phosphorus concentrations observed during the same period at the upstream impact sites thus the relatively higher concentrations of total phosphorus in August and September are likely not a Mine-related effect and there is no indication that mitigations are required.

The increased periphyton biomass (chlorophyll *a* concentration) in Davidson Creek and Creek 661 are likely attributed to the Mine-related increases in total phosphorus (Section 2.3). Freshwater algae tend to be phosphorus limited and will respond to phosphorus enrichment by increases in biomass (Wetzel 2001). The total phosphorus increases in Davidson Creek in Q1 and Q2 are related to TSS releases. Mine-related sources of total phosphorus to Davidson Creek are being mitigated and thus it is anticipated that total phosphorus and periphyton biomass will decrease in 2026 to levels observed during baseline years.

In addition, the timing of sampling was later in 2024 and 2025 compared to previous years (e.g., 2022 and 2023) which may have contributed to the higher biomass observed in these years due to a longer growing period (Section 5.3.1) and sampling efforts should be prioritized for completion in a similar window as the baseline monitoring.

5.5 SUMMARY AND RECOMMENDATIONS

The 2025 periphyton communities did not indicate a significant change from baseline at impact sites in Davidson Creek and Creek 661. However, evaluation of periphyton growth (measured as biomass) indicated the 2025 concentrations are changing from baseline concentrations but are below levels of concern. The increase periphyton growth may be related to the increase in nutrients (total phosphorus) however sampling in 2025 also took place later in September than in previous years. Thus, the light conditions were likely different and periphyton may have had longer to grow, resulting in higher biomass in 2025 compared to baseline years.

Periphyton biomass and nutrients were assessed against the periphyton and nutrient Response Framework. Exceedance of the periphyton biomass guideline was not observed at the impact sites however the significant increase in growth at Davidson Creek and Creek 661 sites indicates a "medium" action level. Nitrogen species were evaluated as meeting the "none" action level for Davidson Creek and Creek 661 sites except for total ammonia at 661-10 where a "medium" action level was met. Total phosphorus was greater than predicted and baseline concentrations at Creek 661 sites however this was associated with sporadic increases observed in August and September

2025 that did not persist. Therefore, no changes to the current mitigation measures for periphyton growth to protect aquatic life are required at this time. Similar to changes in water quality, the changes in nutrients (total phosphorus) were also likely related to 2025 Mine activities thus the same mitigation measures applied for water quality are applicable to nutrients.

No additional sampling or analyses other than that described in the AEMP Plan, Version 4.0 (ERM 2025b) is recommended.

6. AQUATIC INVERTEBRATES

6.1 MEASUREMENT ASSESSMENT ENDPOINTS

Benthic invertebrates are widely used as indicators of environmental conditions and changes in streams. Stream benthic invertebrate surveys were conducted and abundance, community composition, and diversity metrics at each sampling site were evaluated using Reference Condition Approach (RCA; Table 6.1-1). Using the available RCA models, the potentially impacted sites can be matched to the available reference sites (provided by Canadian Aquatic Biomonitoring Network [CABIN] repository) with similar habitats for comparison of benthic invertebrate communities. The extent of the difference between the monitored benthic invertebrate sites and reference sites (provided by CABIN repository) is the measure of the Mine-related effect. Evaluation of the appropriate reference site model for the RCA was completed and results indicated that the Fraser 2021 reference site model is the most appropriate (ERM 2025b).

TABLE 6.1-1 MEASUREMENT AND ASSESSMENT ENDPOINTS FOR AQUATIC INVERTEBRATES

Measurement Endpoint	Assessment Endpoint
Abundance (number of organisms/unit area)	Reference Condition Approach analysis
Taxonomy (community sampling)	Reference Condition Approach analysis[1]
Tissue metal concentration	• Before-after-control-impact analysis[2] • Comparison to BC tissue residue guidelines for selenium (BC WLRS 2025a) and CCME tissue residue guideline for mercury (CCME 2025d)

Notes:
[1] Abundance, family richness, Simpson's Diversity and Evenness indices, and the Bray-Curtis Index was completed for whole community and the Ephemeroptera, Plecoptera, and Trichoptera taxa.
[2] A control-impact analysis was completed instead because only one year (data point) was available for the "after".

The assessment endpoint for tissue metals analysis would be changes identified at impact sites through BACI analysis. Tissue metal concentrations will also be compared to BC and CCME guidelines for the protection of wildlife consumers of aquatic biota (BC WLRS 2025a; CCME 2025d). The tissue metals assessment can provide an additional line of evidence to aid in the interpretation of the water quality, sediment quality, and/or benthic invertebrate community observations.

6.2 SAMPLING SITES AND METHODS

As defined in the AEMP Plan (ERM 2025b), benthic invertebrate quality samples were collected at sites downstream from the mine site and at control sites, as indicated in Table 1.7-2 and Figure 1.7-1. Sampling sites were co-located with surface water quality sites where there were riffle-pool-riffle sequences. At site 661-05 in 2024, a culvert was installed at the location where sampling at had been conducted in 2022 and 2023, and sampling has since been conducted downstream of the culvert.

6.2.1 FIELD METHODS

Benthic invertebrate sampling was conducted using a kick net following CABIN protocol and was carried out by CABIN-certified field personnel (Environment Canada 2012b). Sampling was completed between September 9 and 17, 2025; concurrent with sediment quality and periphyton sampling.

Prior to conducting benthic invertebrate sampling, a habitat characterization was performed at each site following CABIN protocols (Environment Canada 2012b). This included characterizing the reach (canopy cover, streamside vegetation, periphyton coverage, etc.), in situ water chemistry measurements using a YSI Professional Plus (temperature, pH, conductivity, and dissolved oxygen), channel data (slope, wetted width, velocity, etc.), and substrate data (100-pebble count, embeddedness, etc.).

A standard CABIN kick net (400 µm mesh) was used to collect one sample at each site. Samples were collected by placing the kick net downstream of the collector with the flat bottom of the net resting on the substrate. The sampler then walked backward in an upstream direction dragging the net along the bottom of the stream, disturbing the substrate using a kicking motion. The sampler zigzagged continuously over the stream bottom for 3 minutes using consistent kicking effort. For very small streams, the kicking period was between 1 to 2 minutes. The contents of the kick net sample were transferred to a sieve and sample debris was washed from the net using a wash bottle. Large debris was scrubbed, rinsed, visually inspected to ensure no benthic invertebrates remained, and removed from the sample. The contents were transferred into a clean 1 L, pre-labelled plastic jar and preserved to a final concentration of 10% buffered formalin. Samples were sent to Cordillera Consulting in Summerland, BC for enumeration and identification.

Five additional CABIN kick net samples were collected at each of the stream sampling sites for collection of benthic invertebrates to assess tissue metal concentrations. The stream was sampled using a 400 µm kick net until a sufficient wet weight of benthic invertebrates was collected for each analysis (0.5 g) replicate. A split sample was collected at three of the sites for field quality assurance and quality control. Samples were placed in pre-labelled plastic tubes, sealed, and then frozen until analysis by ALS.

6.2.2 LABORATORY METHODS

6.2.2.1 TAXONOMIC ANALYSIS

Invertebrates were sorted and identified to the lowest possible taxonomic level (usually genus) according to published CABIN protocols (Environment and Climate Chance Canada [ECCC] 2020). Ostracoda, Cladocera, Nematoda, Copepoda, Porifera, Platyhelminthes, and terrestrial organisms were excluded from counts as indicated in the Environment Canada CABIN protocols (ECCC 2020).

6.2.2.2 TISSUE METALS

Tissue metal samples were analyzed for percent moisture and total metals to the lowest possible detection limits consistent with BC ENV (2020; Table 6.2-1).

TABLE 6.2-1 TISSUE METAL METHOD DETECTION LIMITS, 2024

Parameter	Method Detection Limit	Parameter	Method Detection Limit
% moisture	2	Manganese	0.05
Aluminum	5	Total mercury (wwt)	0.005 - 0.016
Antimony	0.01 - 0.02	Molybdenum	0.04
Arsenic	0.03 - 0.05	Nickel	0.2
Barium	0.05	Phosphorus	10 - 20
Beryllium	0.01	Potassium	20
Bismuth	0.01	Rubidium	0.05
Boron	1	Selenium	0.1
Cadmium	0.01	Sodium	20
Calcium	20	Strontium	0.1
Cesium	0.005	Tellurium	0.02
Chromium	0.2	Thallium	0.002
Cobalt	0.02	Tin	0.1
Copper	0.2	Uranium	0.002
Iron	5	Vanadium	0.1
Lead	0.05	Zinc	1
Lithium	0.5	Zirconium	0.2
Magnesium	2		

Notes:
Units are mg/kg dry weight unless otherwise indicated.

6.2.2.3 QUALITY ASSURANCE/QUALITY CONTROL

Sampling was conducted by CABIN-certified personnel, following CABIN field protocols (Environment Canada 2012b). One duplicate taxonomy sample was collected, and five replicate benthic tissue samples were collected at each site to provide data on the within site variability. Field split duplicate samples were collected at the rate of 10% of the total number of samples, where one sample (replicate) was split in half and the split sample was submitted as a blind sample for laboratory analysis. Chain of custody forms were used for all benthic invertebrate samples.

Quality assurance/quality control for laboratory analysis of benthic invertebrate taxonomy samples followed CABIN protocols (ECCC 2020), which included determining the sorting efficiency of the subsampled benthic invertebrates and the percent similarity of samples identified by two separate taxonomists. The reproducibility of subsampling and taxonomy was tested on 9% of benthic invertebrate samples (1 out of 11 samples). The percent similarity of ≥ 90% was the data quality objective. If this was not met, the reasons for the discrepancies between taxonomists were discussed. If major discrepancies were found, then the samples were recounted.

For the benthic invertebrate tissue metal samples, analyses were conducted by a CALA-certified laboratory. Laboratory QA/QC practices were consistent with those required by BC ENV (2020a). and included reference material, method blanks, and laboratory control substances (as defined in Section 2.1.2).

6.2.3 DATA ANALYSIS

6.2.3.1 STUDY QUESTION 1—ABUNDANCE AND COMMUNITY COMPOSITION METRICS COMPARISON TO REFERENCE CONDITION

To answer the first study question (*Are AEMP component assessment endpoints at impact sites changing from baseline conditions or reference ranges as a result of the Mine?*), benthic abundance and community metrics in the "after" period (i.e., 2024 and 2025) were compared to the reference condition.

Community descriptors were calculated from the taxonomic results, including benthic invertebrate abundance, family richness, Simpson's Diversity and Evenness indices, and the Bray-Curtis Index. Abundance, richness, diversity, and evenness calculations were performed on the whole community as well as the orders Ephemeroptera, Plecoptera, and Trichoptera (EPT) taxa. The abundance, richness, diversity, and evenness of Ephemeroptera, and the families within Order Ephemeroptera, specifically focusing on Family Heptageniidae, were also calculated.

Family richness was calculated as the total number of benthic invertebrate families present in each replicate sample. The Simpson's Diversity Index (D) is calculated as:

$$D = 1 - \sum_{i=1}^{F} (p_i)^2$$

where:
F = number of families present (i.e., family richness), and
p_i = relative abundance of each family calculated as n_i/N, where n_i is the number of individuals in family i, and N is the total number of all individuals.

Simpson's Evenness Index (E) is calculated as:

$$E = 1 / \sum_{i=1}^{F} (p_i^2) / F$$

where:
E = evenness,
F = number of families present (i.e., family richness), and
p_i = relative abundance of each family calculated as above.

A complete dissimilarity matrix was also generated that included pairwise comparisons of all samples using the Bray-Curtis Index comparing all sites sampled during the 2025 field sampling with reference sites located in the Fraser Plateau that are stored in the CABIN repository and used to build the Fraser 2021 Benthic Assessment of Sediment (BEAST) model. The regional control sites (705-05, 705-10, and FC-01) and 661-01 sampled during construction in 2024 were not included in the reference sites within the Fraser 2021 model, as this model was built with data collected between 1994 and 2019. The Bray-Curtis Index compared the community composition within a benthic invertebrate community sample to the median reference community composition in the CABIN database. This reference composition was generated from the median abundance of

each represented family from each of the control site replicates. Since the median reference composition was generated from the combined control site replicates, the comparison of a single control site replicate community to the median reference community composition produced a dissimilarity value (although typically a much lower value than exposure sites). Because the Bray-Curtis Index measures the percent difference between sites, the greater the dissimilarity value between a site and the median reference community, the more dissimilar those benthic invertebrate communities are. The Bray-Curtis Index ranges from 0 to 1, with 1 representing completely dissimilar communities, and 0 representing identical communities. This index was calculated as:

$$\textit{Bray-Curtis Index (BC)} = \sum_{i=1}^{F} |yi1 - yi2| \; / \; \sum_{i=1}^{F} |yi1 + yi2|$$

where:
BC = Bray-Curtis distance between sites 1 and 2,
n = total number of families present at the two sites,
yi1 = count for family i at site 1, and
yi2 = count for family i at site 2.

River Invertebrate Prediction and Classification System (RIVPACS) was calculated using the CABIN online repository and in-built software to assess the benthic invertebrate community composition at potential impact sites. The RIVPACS uses benthic invertebrate presence/absence data compared against expected taxa (O:E ratios). Under RIVPACS, where taxa are absent but are expected to be present, the assumption is that some environmental condition is impacting the community. The RIVPACS uses reference sites (from the CABIN repository) to determine which taxa are expected to be present. An O:E ratio close to 1 would indicate that impacted sites are in good condition based on the observed present taxa at impacted sites compared to reference sites (from the CABIN repository).

Similarly, the BEAST analysis used the habitat characteristics to infer what the benthic invertebrate community would be, assuming that unimpacted sites with the same habitat would contain a benthic invertebrate community similar to reference sites. Turtle Creek sites TC-01 and TC-05 were not included in BEAST analysis because sampling at these sites necessitated a modified CABIN sampling protocol that resulted in data not meeting assumptions for interpretable and comparable BEAST analysis results. The 2025 field sampling were compared to habitats from reference sites located in the Fraser Plateau that are stored in the CABIN repository. These stored reference sites, sampled between 1994 and 2019, were used to build the Fraser 2021 Benthic Assessment of Sediment (BEAST) reference model and were used to identify habitat predictor variables for the benthic invertebrate community. Predictor variable values for the sites sampled in 2025 were determined using GIS datasets and added to the CABIN study repository. These predictor variables were used in BEAST analysis to assign an expected benthic invertebrate group based on habitat characteristics. The regional control sites (705-05, 705-10, and FC-01) and 661-01 sampled during construction in 2025 were not included in the reference sites within the Fraser 2021 model.

It is hypothesized that if mine activities affected benthic invertebrate communities, then there would be a significant divergence of benthic invertebrate abundance or community composition from the control sites and/or the CABIN reference site model despite having similar habitats as reference sites.

6.2.3.2 STUDY QUESTION 1—TISSUE METAL COMPARISON TO BASELINE

To answer the first study question (*Are AEMP component assessment endpoints at impact sites changing from baseline conditions or reference ranges as a result of the Mine?*), benthic tissue metal concentrations in the "after" period (i.e., 2024 and 2025) were compared to baseline years and Year 1 of Construction (2017, 2021, 2022, and 2023).

For the purpose of data analysis and presentation, half of the DL was calculated when parameter concentrations were less than the DL (BC MOE 2016b).

Summary statistics of metal concentrations by site (mean, median, standard deviation, standard error) were calculated. Plots were generated by watershed to assess tissue metal concentrations in baseline years (2012, 2017, and 2022), construction (2023 and 2024), and operation (2025), at both the control and impact sites. The numeric performance benchmark for each watershed was calculated as the 95th percentile of tissue concentrations during baseline years and Year 1 of Construction. The 2025 mean tissue metal concentration was compared to the watershed specific numeric performance benchmark.

The BACI statistical was completed for mercury and selenium where tissue residue guidelines exist (CCME 2025d; BC WLRS 2025a). There were significant increases of total aluminum in Davidson Creek and Creek 661 surface waters that exceeded WQG-AL (Section 2.3) therefore aluminum (in addition to selenium and mercury) was also included in the statistical BACI evaluation.

A BACI statistical analysis was performed on benthic tissue metals for each watershed. The BACI analysis for benthic invertebrate tissue metal concentrations introduces a class effect to a mixed model ANOVA, which is based on the classification of a site as an impact or a control site. The "control" sites included the regional control sites FC-01, 705-05, and 705-10 for both watersheds, and 661-01 for sites in the Creek 661 watershed. The "impact" sites were DC-05 and DC-15 in the Davidson Creek watershed, and 661-05, and 661-10 in the Creek 661 watershed. Year was included as a random effect variable to control for inter-annual variability in benthic invertebrate tissue metal concentration. The "before" period was the data collected in baseline (2012, 2017, and 2022) and Year 1 of Construction (2023). The Year 1 of Construction (2023) was added to the "before" period because there were limited construction activities and no surface water discharge in 2023 (ERM 2025b). The "after" period was data collected in 2024 and 2025.

The BACI analyses tested the hypothesis that if mine activities affected benthic invertebrate tissue metals, the expectation would be a significant change in tissue metal concentration at impact sites in comparison with baseline concentrations not observed at control sites. If both impact and control sites experienced a parallel change over time, then it would be likely a change over a larger spatial scale affected all control and impact sites, and it is unlikely that construction activities or operations affected benthic invertebrate tissue metals.

Analysis was performed using the most recent R statistical computing package (R Core Team 2025). Data transformations (e.g., log transformation) were completed if determined to be appropriate (e.g., to achieve random distribution of residuals).

The interaction between the period ("before" or "after") and class (impact or control) effects would indicate whether any before-after change in the mean tissue metal concentration occurred

in the impact site also occurred in the control site(s). The overall site (control versus impact) and period ("before" versus "after") interaction significance (p-value less than significance level (α) of 0.05) was assessed using an F test. To reduce the number of false positives (Type I error) due to the large number of statistical tests conducted, multiple test correction was applied.

6.2.3.3 STUDY QUESTION 3—TISSUE METAL COMPARISON TO GUIDELINES

Tissue metal concentrations were compared to BC and CCME tissue guidelines as indicated in Table 6.2-2 (BC WLRS 2025a; CCME 2025d). For the purpose of this comparison, measurements of mercury in benthic invertebrate tissue samples were assumed to be 100% methylmercury. While actual concentrations of methylmercury are likely to be slightly less than the total concentration, this assumption provides a conservative estimate of methylmercury in benthic invertebrate tissues from total mercury concentrations.

TABLE 6.2-2 ESTABLISHED TISSUE METAL GUIDELINES FOR THE PROTECTION OF WILDLIFE CONSUMERS OF AQUATIC BIOTA

Parameter	Source	Guideline Type	Guideline Value
Mercury (methylmercury)	CCME 2025d, BC WLRS 2025a	Protection of wildlife consumers of aquatic resources	0.033 mg/kg wwt
Selenium	BC WLRS 2025a	Protection of aquatic health	4 mg/kg dwt

Notes:
BC WLRS = BC Ministry of Water, Land and Resource Stewardship; CCME = Canadian Council of Ministers of the Environment.
dwt = dry weight; wwt = wet weight.

6.2.3.4 QUALITY ASSURANCE/QUALITY CONTROL

Aquatic invertebrate densities and tissue metal concentrations are presented as means with standard errors to assess the variability of samples collected for each site and/or period of time. For each invertebrate tissue metal field split samples, the RPD (as defined in Section 2.2.4.1) was calculated. Higher RPD is acceptable when concentrations are lower (BC ENV 2013), but caution should be used in interpretation of near MDL concentrations. Outliers were identified using a quantile-quantile plot, where points not following the reference line are suspected outliers. Professional judgement was used in assessing the rationale of removal of an outlier from data sets.

6.3 RESULTS AND DISCUSSION

The 2025 benthic invertebrate taxonomic analysis and taxonomy QA/QC results for sorting efficiency are provided in Appendix D-1 and Appendix D-2. Whole community benthic invertebrate summary statistics are provided in Appendix D-3. Appendix D-4 provides the summaries of the EPT taxa proportion of the total abundance, richness, and community composition. Appendix D-5 provides the percentage of major taxa.

Benthic invertebrate tissue metal samples were collected at sites, as indicated in Table 1.7-1. Samples were collected between September 14 to 18, 2024 (DC-05, 661-01, 661-10, 661-05, and

FC-01) and on October 17, 2024 (DC-15) and submitted to ALS for tissue metal testing. The laboratory results of the 2024 benthic invertebrate tissue metals are provided in Appendix D-6 and RPD of the split samples is provided in Appendix D-7. Summary statistics of benthic invertebrate tissue metal concentrations by site are provided in Appendix D-8. Timeseries graphs of benthic invertebrate tissue concentrations for analyzed metals are provided in Appendix D-9. Comparison to the benthic invertebrate NPM benchmarks is provided in Appendix D-10. The results of the BACI statistical analysis are provided in Appendix D-11.

6.3.1 STUDY QUESTION 1—ABUNDANCE AND COMMUNITY COMPOSITION METRICS COMPARISON TO REFERENCE CONDITION

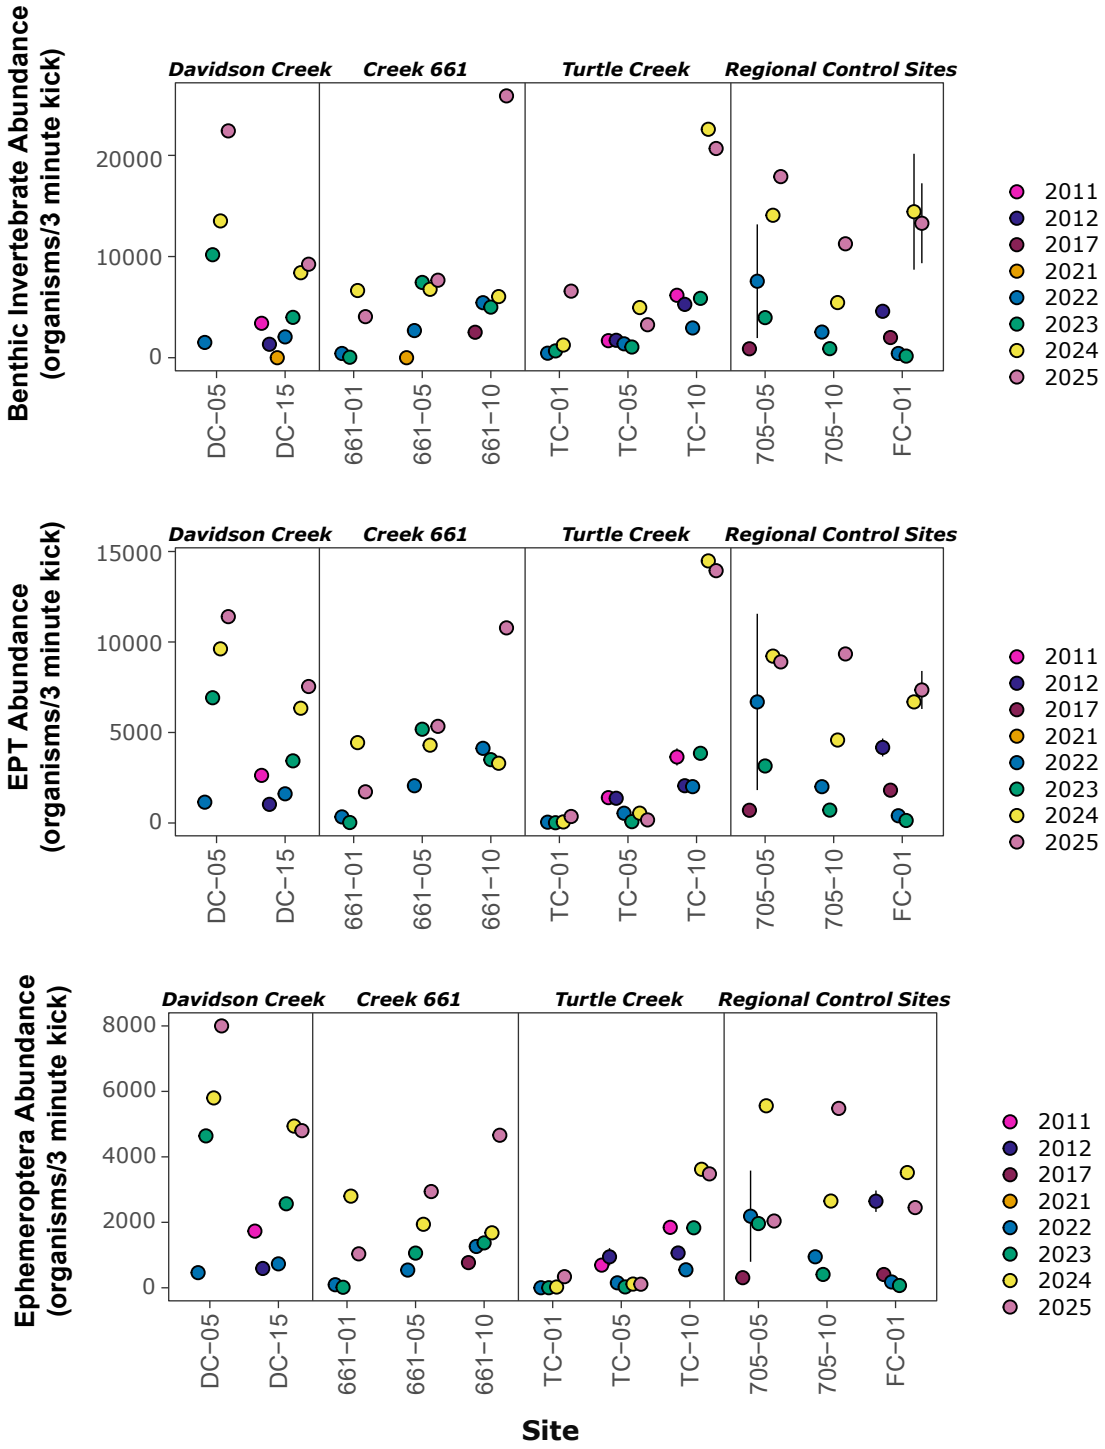
Abundance, community composition, community richness, diversity, and evenness were assessed at AEMP sites in Davidson Creek, Creek 661, Turtle Creek, Creek 705 and Fawnie Creek watersheds, comparing data from 2011 to 2012, 2017 and 2021 to 2025. Assessment of the data in the 2022 Baseline report (ERM 2023) indicated that benthic invertebrate data from 2011 and 2012 were comparable with data collected from 2017, 2021, and 2022. However, Bray Curtis, RIVPACS, habitat, and BEAST analyses did not include the 2011 and 2012 benthic invertebrate community observations because they were not available from the CABIN database. The 2011 and 2012 CABIN study results are presented in AMEC (2013a and 2013b).

6.3.1.1 ABUNDANCE AND COMMUNITY COMPOSITION

The 2025 benthic invertebrate abundance in 2025 was higher across most sites compared to all previous monitoring years, including baseline (2011, 2012, 2017, 2021, 2022) and construction years (2023 and 2024; Figure 6.3-1). Within each watershed, the 2025 abundance was similar among sites, except for Turtle Creek where TC-01 and TC-05 had lower abundance compared to TC-10 (Figure 6.3-1). The 2025 benthic invertebrate community composition consisted of Amphipoda, Annelida, Arachnida, Cnidaria, Coleoptera, Crustacea, Diptera (including Chironomidae), Ephemeroptera, Hexapoda, Mollusca, Plecoptera, and Trichoptera (Figures 6.3-2). Community composition was variable between years at each of the sites with no clear evidence of increasing or decreasing trends (Figure 6.3-2).

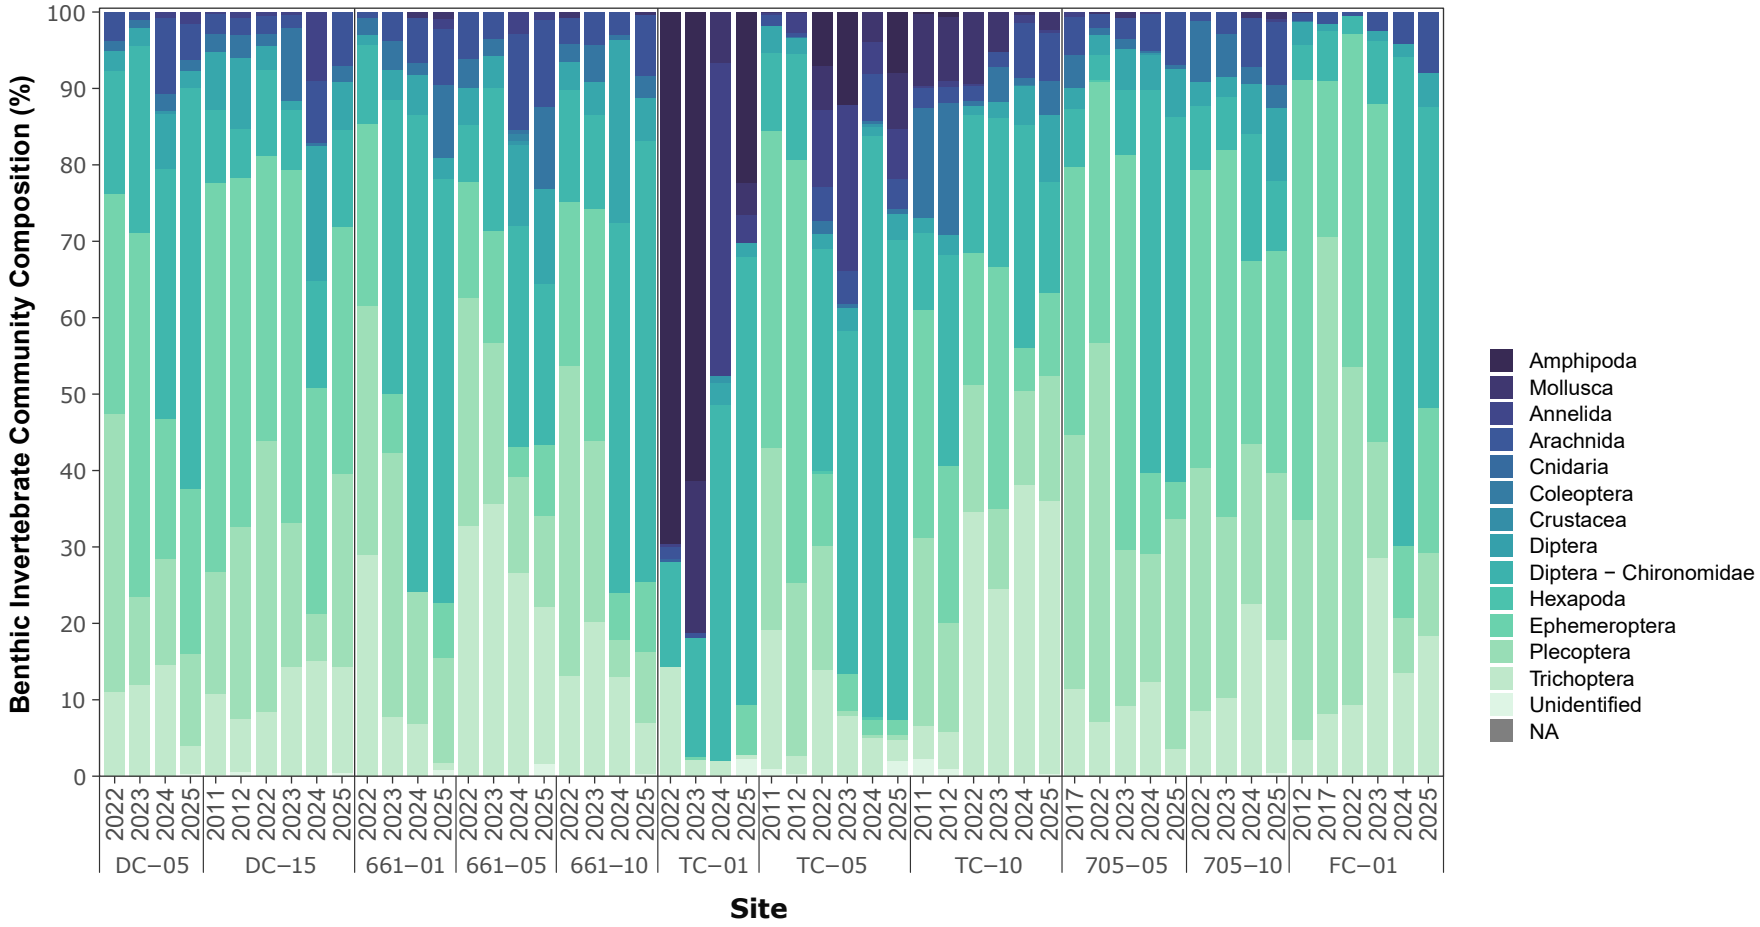
The EPT taxa are considered sensitive to environmental pollution, and their abundance is a sensitive indicator of potential effects from heavy metals. EPT taxa abundance in 2025 was similar to or higher than values during baseline and construction years at most sites (Figure 6.3-1). Higher proportions of EPT taxa were recorded at Davidson Creek, 661-10, 705-05, and FC-01 compared to baseline and construction periods. In contrast, TC-01 and TC-05 continued to exhibit lower EPT abundance in 2025, consistent with reduced values recorded during construction in 2023 and 2024. The range of 2025 EPT taxa abundance as a proportion of the total benthic invertebrate was within the overall range observed during baseline and construction years (2.2% at TC-01 [2023] to 95.9% at FC-01 [2022]; Figure 6.3-1). This similarity to control sites and to baseline years indicated that the 2025 mine activities did not impact benthic invertebrate abundance, including EPT taxa, in the Davidson Creek and Creek 661 watersheds.

FIGURE 6.3-1 BENTHIC INVERTEBRATE COMMUNITY ABUNDANCE, EPT ABUNDANCE, AND EPHEMEROPTERA ABUNDANCE, BASELINE (2011, 2012, 2017, 2021, AND 2022), CONSTRUCTION (2023 AND 2024), AND OPERATIONS (2025)



Notes: Ostracoda, Cladocera, Copepoda, Porifera, Nematoda, fish and terrestrial invertebrates were excluded from all calculations. Platyhelminthes was excluded for 2010 and 2020, but added for 2021 data according to Environment and Climate Change Canada, 2020 protocol. Immature, damaged and unidentified individuals were excluded from all analyses except abundance calculations.

FIGURE 6.3-2 COMMUNITY COMPOSITION OF THE BENTHIC INVERTEBRATE COMMUNITY, BASELINE (2011, 2012, 2017, 2021, AND 2022), CONSTRUCTION (2023 AND 2024), AND OPERATIONS (2025)



Notes: Ostracoda, Cladocera, Copepoda, Porifera, Nematoda, fish and terrestrial invertebrates were excluded from all calculations. Platyhelminthes was excluded for 2010 and 2020, but added for 2021 data according to Environment and Climate Change Canada, 2020 protocol. Immature, damaged and unidentified individuals were excluded from all analyses except abundance calculations.

Ephemeroptera proportions in 2025 were high across most watersheds and were higher than during baseline and construction years, particularly at Davidson Creek, Creek 661, and the regional control sites (Figure 6.3-3). High EPT proportions were observed at DC-15 (71.4%), 705-10 (68.3%), and TC-10 (62.9%), while TC-01 (7.0%) and TC-05 (5.3%) remained comparatively low (Figure 6.3-3). Across the remaining sites, EPT proportions ranged from moderate to high, including DC-05 (37.2%), 661-05 (41.6%), 661-10 (25.1%), 661-01 (21.8%), 705-05 (38.3%), and FC-01 (48.0%; Figure 6.3-3). Relative to baseline and construction years, the 2025 EPT proportions were within the historical range (0 to 97.1%; Figure 6.3-3). Relative to construction years, when Ephemeroptera proportions were frequently reduced (e.g., 0% at TC-01, 6.1% at 661-10, and 9.3% at FC-01 in 2024), the 2025 values were higher, indicating a return toward pre-construction conditions (Figure 6.3-3).

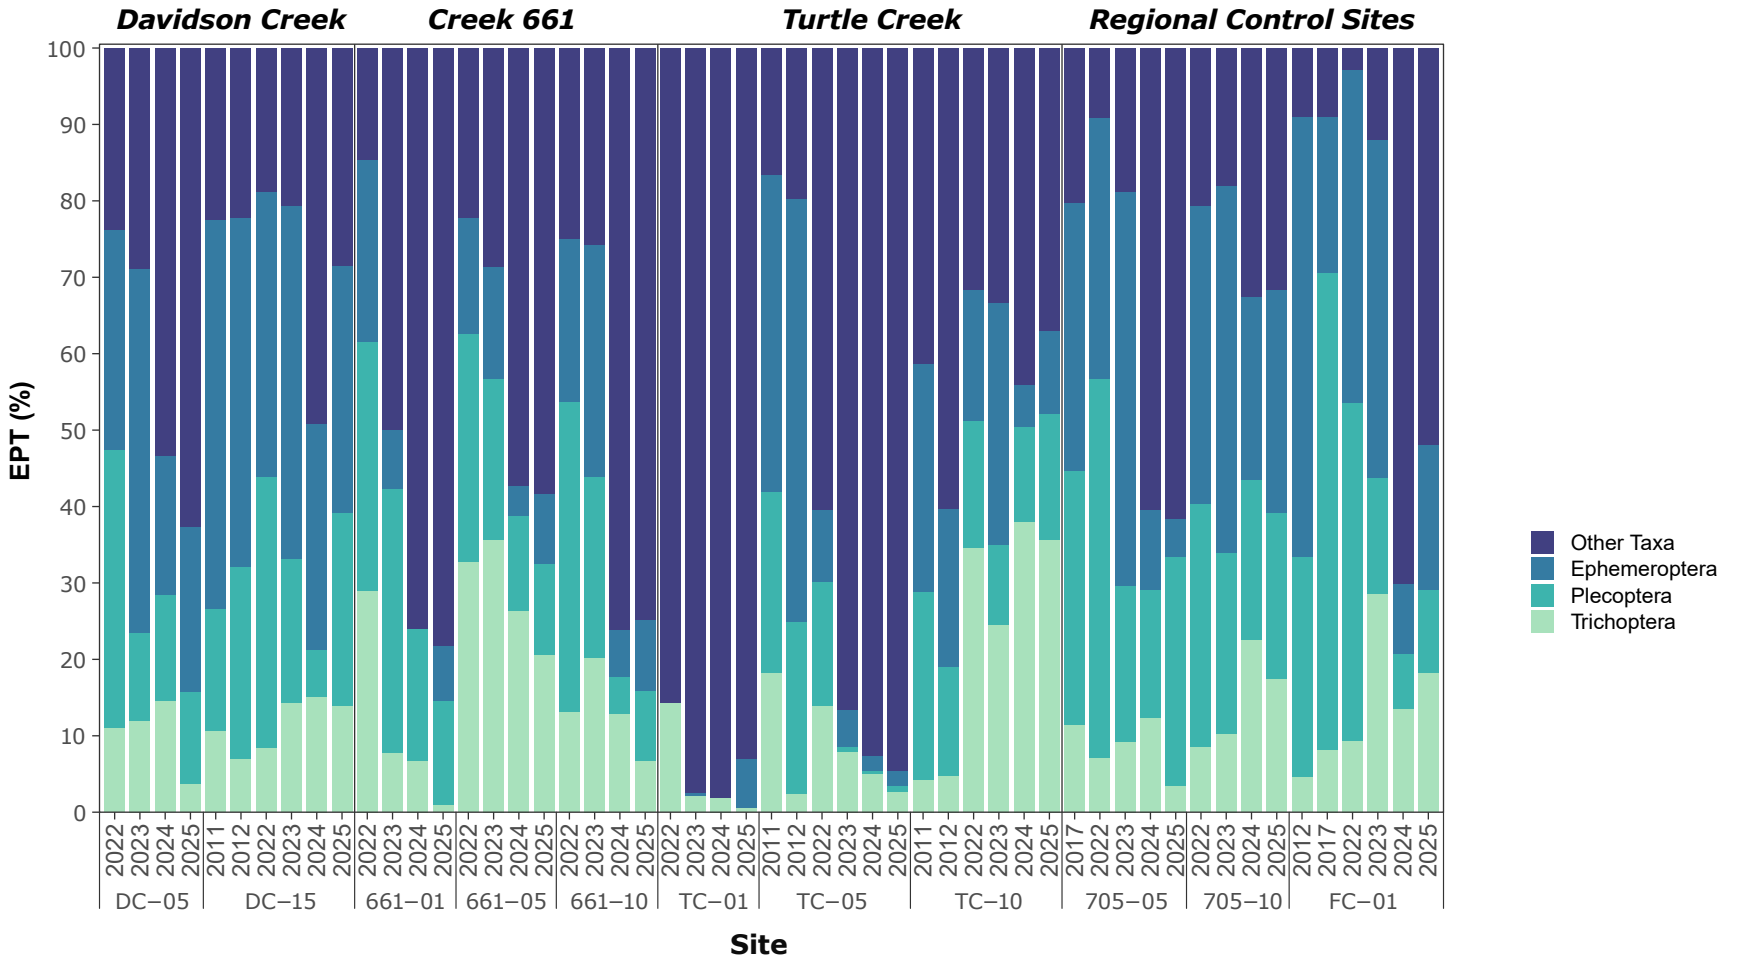
Within the Order Ephemeroptera, Heptageniidae proportions in 2025 were within the range observed during baseline and construction years (Figure 6.3-4). For both impact and control sites, the proportion of Heptageniidae was variable with no consistent annual trends (Figure 6.3-4). In 2025, most sites were similar to or greater than during baseline years and only two sites were significantly lower (i.e., DC-05 and TC-01). Patterns in Davidson Creek and Creek 661 aligned with upstream and regional control sites, indicating no evidence of effects on benthic invertebrate communities during the first year of operations.

Habitat conditions associated with beaver activity in Turtle Creek may have contributed to reduced benthic invertebrate abundance in 2025. TC-01 and TC-05 had four to eight times fewer organisms than TC-10, similar to the pattern observed during the construction years. Both TC-01 and TC-05 had evidence of upstream beaver dams, and these reaches were deeper and more stagnant, with wetland or pool characteristics rather than flowing stream habitat. TC-10 continued to exhibit shallow, flowing water with riffle and run features and coarse substrates. These habitat differences likely explained the consistently lower benthic invertebrate abundance at TC-01 and TC-05 compared to TC-10 across both construction and operations years (Figure 6.3-1).

6.3.1.2 RICHNESS AND DIVERSITY

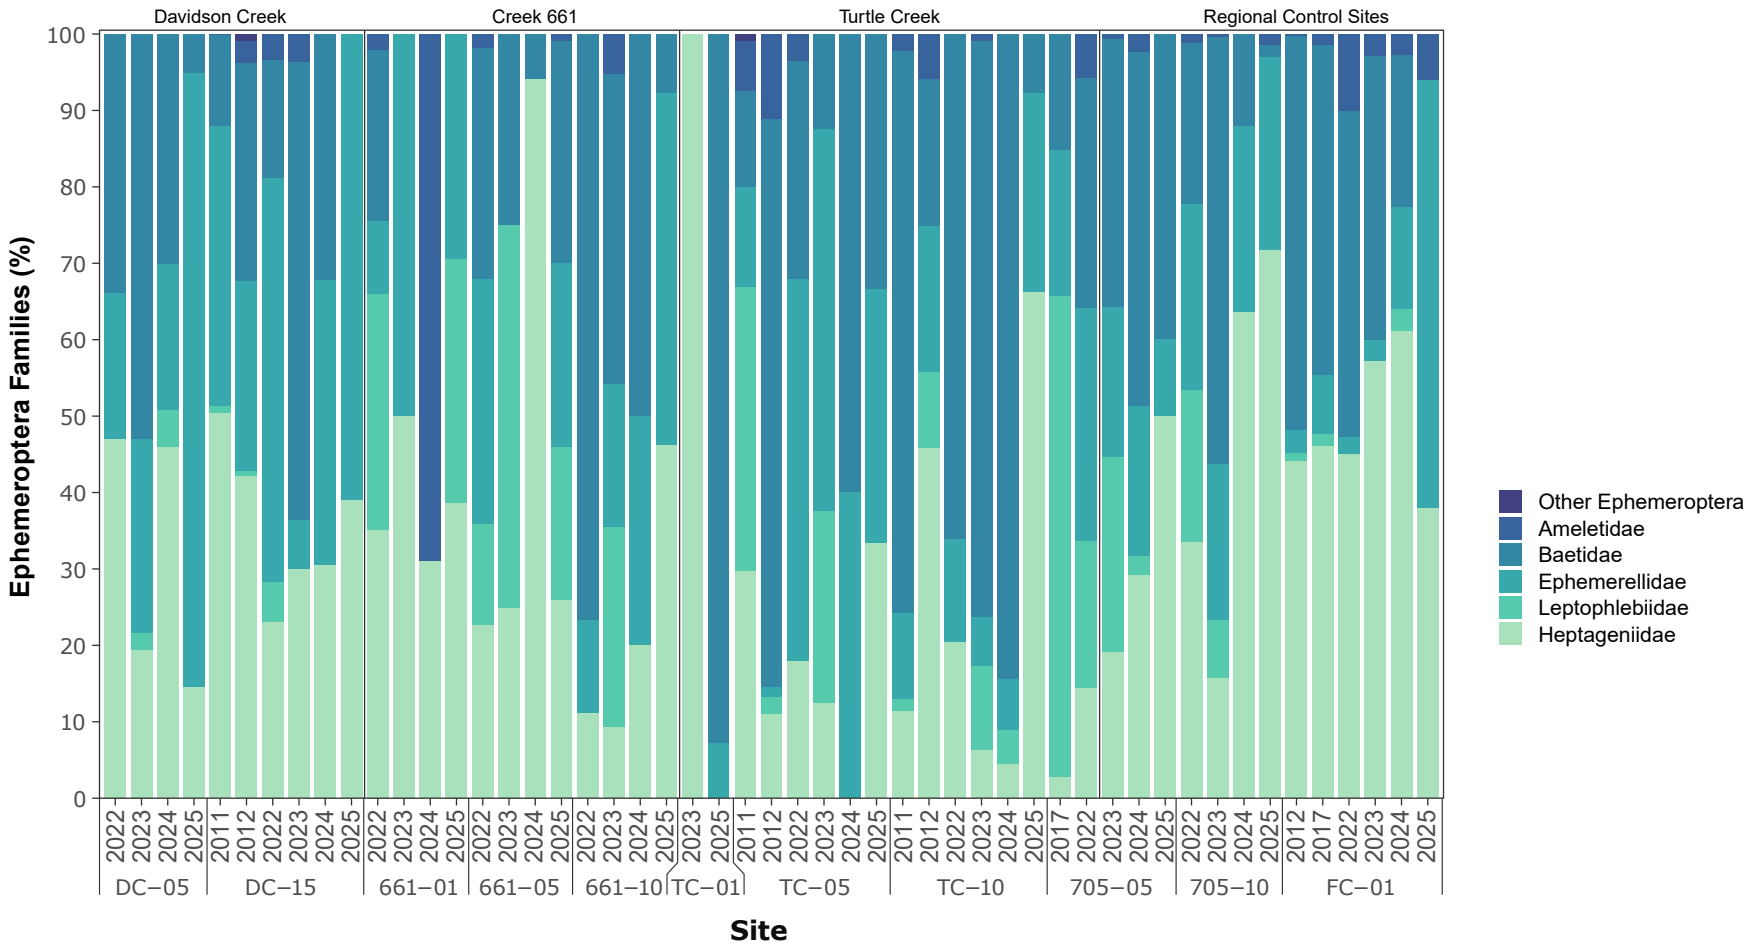
In 2025, family richness was within the baseline (2011, 2012, 2017, 2021, 2022) and construction (2023 and 2024) range of 6 to 29 families (Figure 6.3-5). With the exception of TC-01, richness was similar between impact and control sites and comparable to values observed during baseline and construction years. The lower richness at TC-01 remained consistent with habitat conditions influenced by upstream beaver dams (Figure 6.3-5). In 2025 EPT richness values were similar or lower compared to baseline values, except for FC-01, which were higher relative to construction years (2023; Figure 6.3-5). In 2025, Ephemeroptera richness ranged from 3 to 5 families, which was within the baseline range of 1 to 5 families, and similar to construction range of 1 to 5 families (Figure 6.3-5). Overall, 2025 richness patterns for total families, EPT families, and Ephemeroptera families were consistent with baseline and construction year patterns, indicating no evidence of effects on richness metrics during the first year of operations.

FIGURE 6.3-3 COMMUNITY COMPOSITION OF EPHEMEROPTERA, PLECOPTERA, AND TRICHOPTERA IN THE BENTHIC INVERTEBRATE COMMUNITY, BASELINE (2011, 2012, 2017, 2021, AND 2022), CONSTRUCTION (2023 AND 2024), AND OPERATIONS (2025)



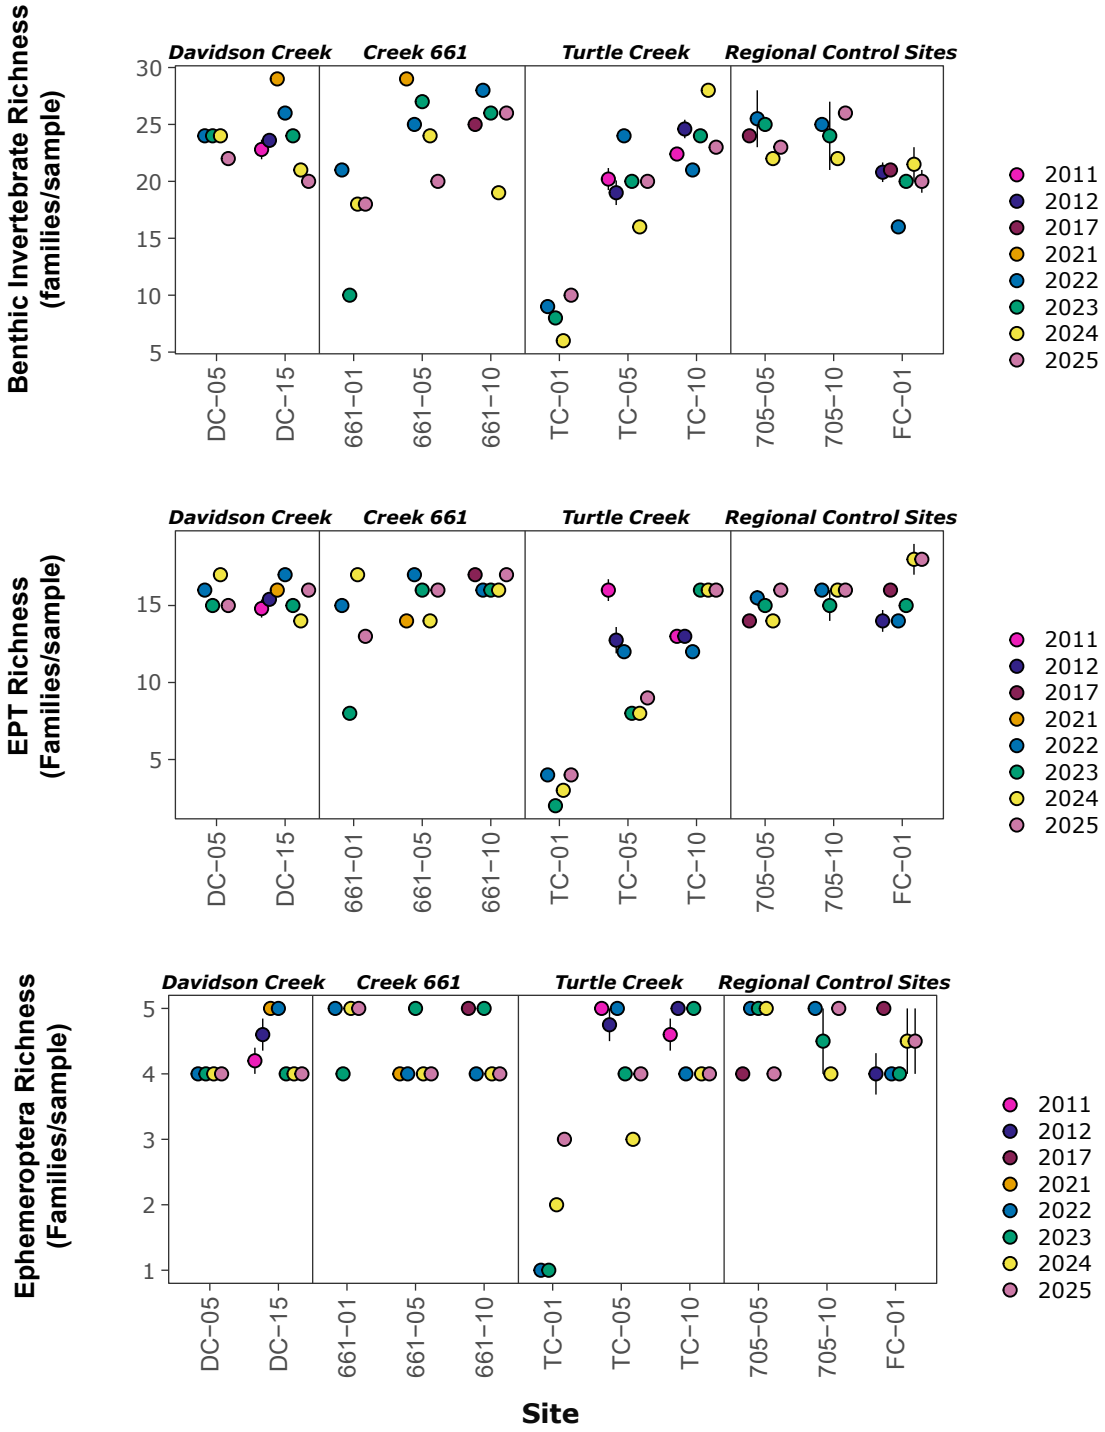
Notes: Ostracoda, Cladocera, Copepoda, Porifera, Nematoda, fish and terrestrial invertebrates were excluded from all calculations. Platyhelminthes was excluded for 2010 and 2020, but added for 2021 data according to Environment and Climate Change Canada, 2020 protocol. Immature, damaged and unidentified individuals were excluded from all analyses except abundance calculations.

FIGURE 6.3-4 COMMUNITY COMPOSITION OF EPHEMEROPTERA THAT IS HEPTAGENIIDAE, BASELINE (2011, 2012, 2017, 2021, AND 2022), CONSTRUCTION (2023 AND 2024), AND OPERATIONS (2025)



Notes: Ostracoda, Cladocera, Copepoda, Porifera, Nematoda, fish and terrestrial invertebrates were excluded from all calculations. Platyhelminthes was excluded for 2010 and 2020, but added for 2021 data according to Environment and Climate Change Canada, 2020 protocol. Immature, damaged and unidentified individuals were excluded from all analyses except abundance calculations.

FIGURE 6.3-5 BENTHIC INVERTEBRATE COMMUNITY RICHNESS, EPT RICHNESS, AND EPHEMEROPTERA RICHNESS, BASELINE (2011, 2012, 2017, 2021, AND 2022), CONSTRUCTION (2023 AND 2024), AND OPERATIONS (2025)



Notes: Ostracoda, Cladocera, Copepoda, Porifera, Nematoda, fish and terrestrial invertebrates were excluded from all calculations. Platyhelminthes was excluded for 2010 and 2020, but added for 2021 data according to Environment and Climate Change Canada, 2020 protocol. Immature, damaged and unidentified individuals were excluded from all analyses except abundance calculations.

Simpson's diversity in 2025 were typically within the range observed during baseline and construction years (0.4 to 1.0; Figure 6.3-6). Evenness in 2025 was lowest at 705-10 (0.042) and highest at TC-01 (0.170; Figure 6.3-7), a range similar to baseline and construction years (0.034 to 0.277; Figure 6.3-7). Diversity within sites were similar across monitoring years, except for 661-10, 705-05, and DC-05 which were lower in 2025 relative to both baseline and construction years (Figure 6.3-6 and Figure 6.3-7). Diversity at TC-01 and TC-05 in 2025 was less than all other sites, similar to the values reported in construction years (Figure 6.3-6); evenness at TC-01 and TC-05 were also higher than other sites in 2025 (Figure 6.3-7). This difference is likely due to a beaver dam upstream of the reach that resulted in a very homogenous community dominated by Amphipoda. Changes in diversity and evenness are not likely related to construction activities and instead related to the inherent variability of benthic invertebrate communities.

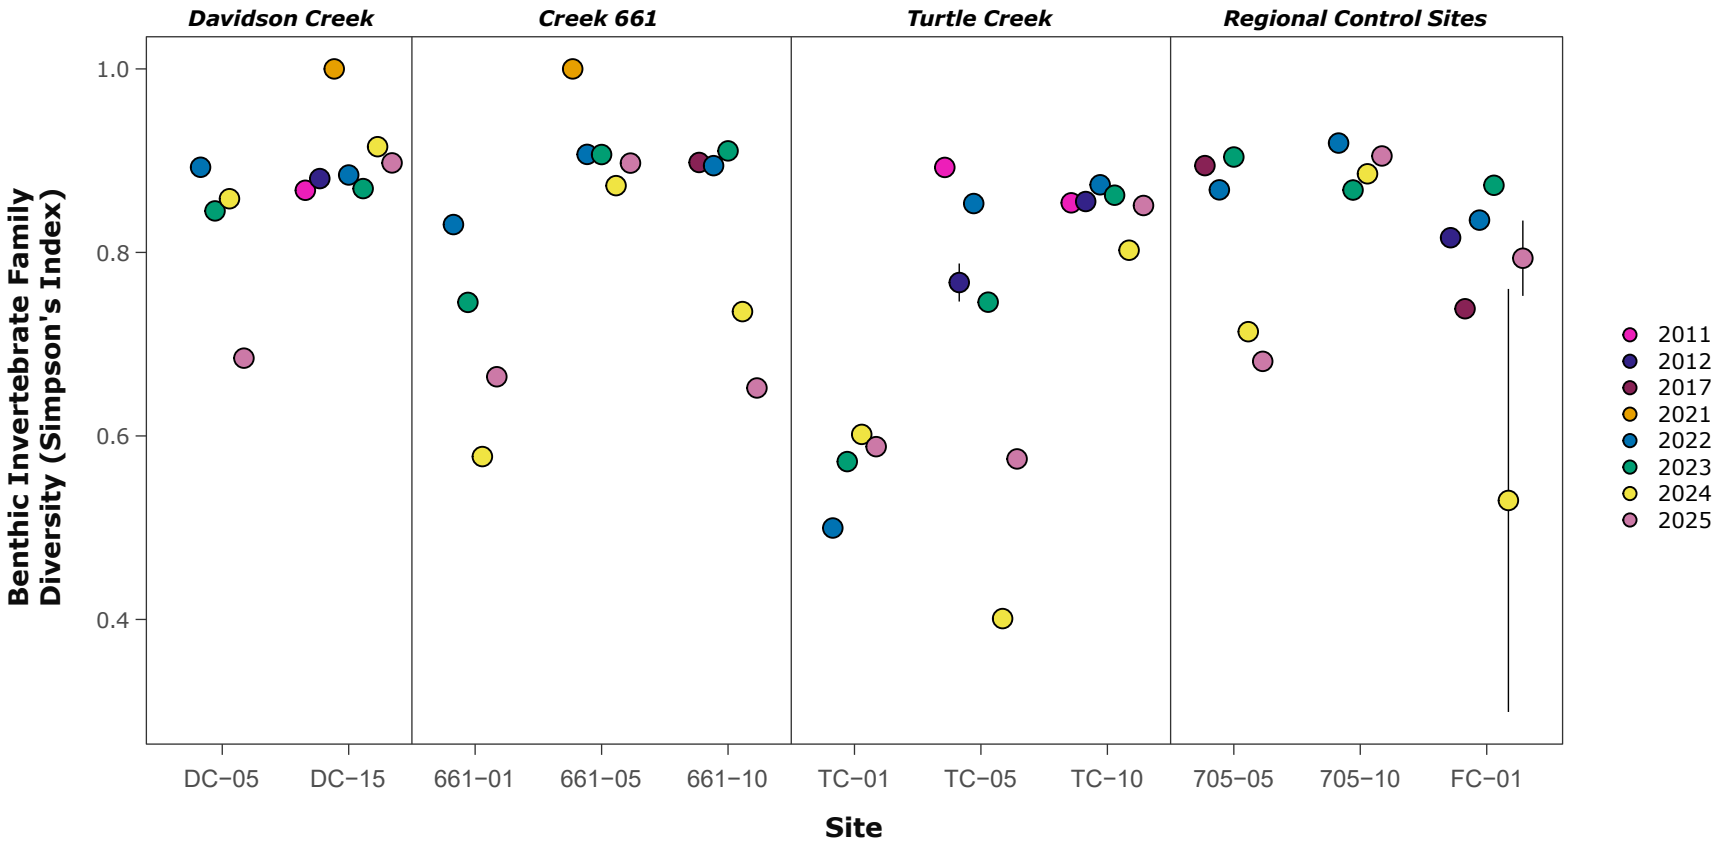
6.3.1.3 COMMUNITY BASED INDICES (BRAY- CURTIS AND RIVPACS)

Two community-based indices, the Bray-Curtis dissimilarity index and RIVPACS, were calculated for impact sites in Davidson Creek and Creek 661 and for sites in Turtle Creek using the CABIN benthic invertebrate data (Tables 6.3-1 and 6.3-2).

In 2025, Bray-Curtis dissimilarity scores were 0.75 at DC-05 and 0.52 at DC-15, indicating higher dissimilarity at DC-05 compared to both baseline and construction years and similar dissimilarity at DC-15 relative to 2022, 2023 and 2024 (Table 6.3-1). In Creek 661, Bray-Curtis scores ranged from 0.39 at 661-05 to 0.70 at 661-10, with 661-05 lower than all previous years (i.e., most similar to reference) and 661-10 higher than 2023 and 2024, but similar to 2022. In Turtle Creek, Bray-Curtis scores ranged from 0.52 at TC-01 to 0.77 at TC-05. TC-01 decreased substantially relative to all previous years, while TC-05 and TC-10 had higher dissimilarity than in 2024. The 2025 reference means used for comparison were 0.39 ± 0.12 for DC-05, DC-15, 661-05, 661-10, and TC-05; and 0.47 ± 0.14 for 661-01, TC-01, and TC-10. Overall, the 2025 Bray-Curtis index indicated moderate dissimilarity between most impact sites and the CABIN reference communities, with the greatest dissimilarity from the CABIN reference communities occurring at DC-05 and 661-10 (> 0.70). For 661-10, a higher index was observed in 2022, but for DC-05, 2025 had the highest dissimilarity score recorded in all monitored years and may be related to an increase in Diptera (Chironomidae).

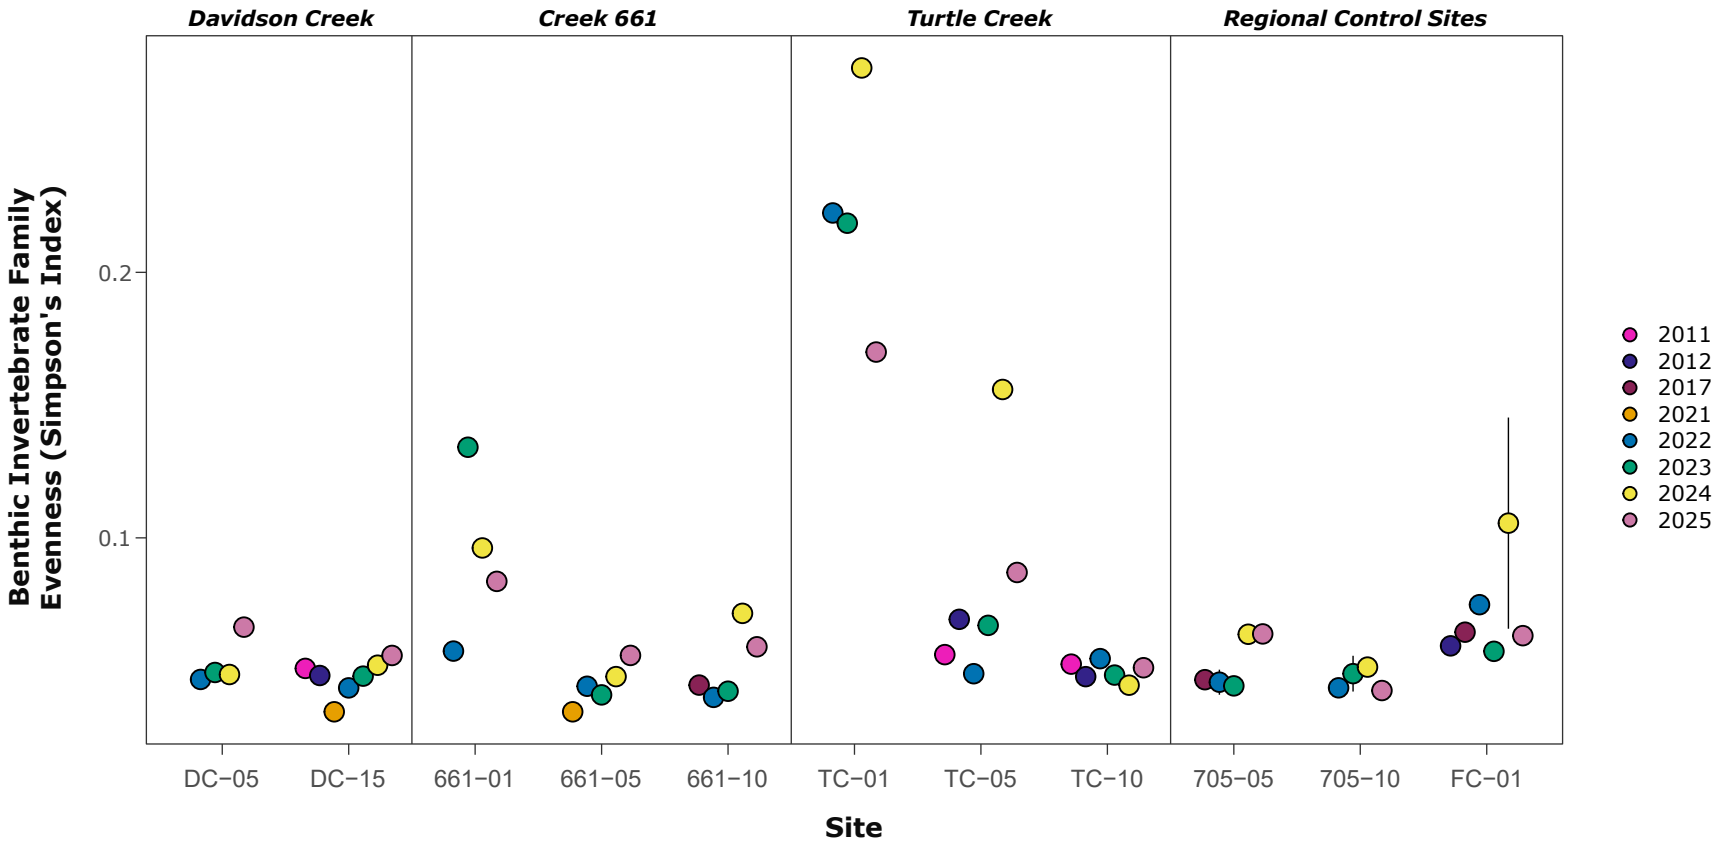
The RIVPACS O:E ratios at DC-05 and DC-15 (1.14) remained similar to baseline and to construction years, indicating that benthic invertebrate assemblages continued to align with expected taxa under reference conditions (Table 6.3-2). In Creek 661, O:E ratios in 2025 ranged from 1.12 at 661-01 to 1.14 at 661-05 and 661-10, consistent with values from 2023 and 2024 and within the range of baseline years (Table 6.3-2). These ratios near 1 indicate that sites potentially influenced by construction and operations activities remained in good condition in 2025. In Turtle Creek, O:E ratios were 0.57 at TC-01 and TC-05 and 1.14 at TC-10. The lower ratios at TC-01 and TC-05 were consistent with previous years and reflect habitat characteristics not typical of streams, such as reduced flow and wetland-like conditions. The similarity of RIVPACS scores between 2025 and baseline at Davidson Creek and Creek 661 indicates that construction and operation activities do not appear to affect benthic invertebrate habitat in these watersheds.

FIGURE 6.3-6 BENTHIC INVERTEBRATE COMMUNITY DIVERSITY, BASELINE (2011, 2012, 2017, 2021, AND 2022), CONSTRUCTION (2023 AND 2024), AND OPERATIONS (2025)



Notes: Ostracoda, Cladocera, Copepoda, Porifera, Nematoda, fish and terrestrial invertebrates were excluded from all calculations. Platyhelminthes was excluded for 2010 and 2020, but added for 2021 data according to Environment and Climate Change Canada, 2020 protocol. Immature, damaged and unidentified individuals were excluded from all analyses except abundance calculations.

FIGURE 6.3-7 BENTHIC INVERTEBRATE COMMUNITY EVENNESS, BASELINE (2011, 2012, 2017, 2021, AND 2022), CONSTRUCTION (2023 AND 2024), AND OPERATIONS (2025)



Notes: Ostracoda, Cladocera, Copepoda, Porifera, Nematoda, fish and terrestrial invertebrates were excluded from all calculations. Platyhelminthes was excluded for 2010 and 2020, but added for 2021 data according to Environment and Climate Change Canada, 2020 protocol. Immature, damaged and unidentified individuals were excluded from all analyses except abundance calculations.

TABLE 6.3-1 BENTHIC INVERTEBRATE BRAY-CURTIS DISSIMILARITY SCORES FOR THE ENTIRE COMMUNITY, BASELINE (2017, 2021, AND 2022), CONSTRUCTION (2023 AND 2024), AND OPERATIONS (2025)

Site	Bray-Curtis Score					
	2017	2021	2022	2023	2024	2025

	TC-10	-	-	0.93	1.13	1.13	1.14

Note:
O:E (p > 0.7) = Observed-to-Expected ratio at an expected probability greater than 70%.

6.3.1.4 REFERENCE CONDITION APPROACH

The RCA assumes that creeks with similar habitats, including riparian areas, will have similar benthic invertebrate communities (ECCC 2014). Models of reference sites are created using the habitat and benthic invertebrate data from sites considered to be unimpacted by anthropogenic disturbance (i.e., pristine sites). Habitat and benthic invertebrate data were collected at AEMP

sites in Davidson Creek, Creek 661, Creek 705, and Fawnie Creek watersheds following CABIN field methods (ECCC 2014) to ensure comparability with the reference sites in CABIN. According to the RCA, formalized in CABIN BEAST model, assessed sites with the same habitat as reference sites are expected to have the same benthic community, and the more different the community is, the more divergent the site is from reference.

The Mine site falls within the Fraser Plateau ecoregion within the Bulkley Valley Ecosection, as defined by CABIN. This area is a broad rolling plateau with a sub-continental climate, numerous lakes, wetlands, and streams, and periodically receives moisture from the Kitimat Ranges (BC ENV 2018). The area surrounding the Mine was historically logged and subsequently reforested. The Fraser 2021 model (Reynoldson, 2021) was determined to be the most applicable BEAST model and was used to compare sites in the Fawnie Creek and Creek 705 watersheds (regional controls), Davidson Creek and Creek 661 (sites expected to be impacted by construction, except 661-01, which is the upstream control). The Turtle Creek sites were not assessed because no construction activities (i.e., airstrip construction) occurred upstream of TC-10 and both sites TC-01 and TC-05 were excluded from BEAST analysis based on "non-stream" habitat classification through consultation with ECCC (M. Gledhill, personal communication).

Habitat Characterization

The results of the habitat characterization completed in 2025 at each of the AEMP sites was similar to the characterizations completed during baseline years (2017, 2021, 2022) and construction years (2023 and 2024; Table 6.3-3).

The control and impact streams where benthic invertebrate sampling were completed in 2025 resembled the habitat conditions observed during baseline years and construction monitoring years, particularly in channel morphology, substrate composition, and riparian vegetation. These streams remained forested, with moderate riparian canopy cover at most sites and similar vegetation communities as previous years (shrubs, coniferous trees, and deciduous trees). Water characteristics measured in 2025 were consistent with prior years, with cool temperatures, low turbidity, and dissolved oxygen concentrations typically above 8 mg/L. Conductivity at most sites in 2025 ranged from approximately 31 µS/cm to 100 µS/cm in the Creek 661, Creek 705, and Davidson Creek watersheds similar to values recorded in earlier years. Turtle Creek conductivity was higher than other watersheds, with 2025 values between approximately 128 µS/cm and 176 µS/cm, consistent with observed patterns since 2017. Turbidity also remained low in 2025, generally between 0 NTU and 4 NTU across all monitored streams in 2025.

Habitat structure at most sites in 2025 consisted of riffles, runs, and pools with moderate slopes and water velocities. The streambeds remained dominated by gravel, pebble, and cobble substrates. Periphyton presence was similar to patterns observed in previous years, with most sites characterized by thin films (0.5 mm to 1 mm thick) and occasional patches of thicker algae at some sites (e.g., 661-10, 661-01, 705-10, and DC-05). In 2025 macrophyte growth was low across most sampling sites; sites 661-01, FC-01, FC-05, and TC-10 had macrophyte coverage that exceeded >50%, consistent with previous years.

Note: NA = no data collected

Sites TC-01 and TC-05 was different from the other monitored sites in all years characterized, including 2025. These sites occur in open meadow habitat with little to no riparian canopy cover, slow water velocities, and streambeds dominated by fine materials (sand, silt, and clay). Pools were the dominant habitat type and periphyton coverage was variable, sometimes forming thick algal mats. These sites were not assessed further.

Beast Analysis

BEAST classifications were used to assess the similarity of benthic invertebrate communities at impact sites in Davidson Creek (DC-05 and DC-15), Creek 661 (661-01, 661-05, 661-10), and sites in Turtle Creek. BEAST results were compared to the Fraser 2021 model for all years, including baseline (2017, 2021, and 2022), construction (2023 and 2024), and operations (2025). All sites were grouped into either Group 4B or 5 in the model. Group 4B (Group 5 in CABIN) is characterized by higher altitude streams with relatively higher slopes and narrow channels, and they are dominated by Baetidae mayflies and most of the reference sites fall within the Fraser Plateau. Group 5 (Group 6 in CABIN) are characterized by a very diverse community that is dominated by Chironomidae in high altitude, steep streams and a relatively slower flow and are nearly half of the sites lie within the Fraser Plateau.

In 2025, BEAST classifications ranged from "similar to reference" to "divergent" across sites (Table 6.3-4). DC-05 was classified as "divergent" in 2025, shifting from "similar to reference" in 2024. DC-15 remained "mildly divergent," consistent with its classifications since baseline. In Creek 661, 661-01 shifted to "mildly divergent" in 2025 from "similar to reference" in 2024, while 661-05 improved to "similar to reference" compared to its 2024 "mildly divergent" classification. Site 661-10 changed from "similar to reference" in 2024 to "mildly divergent" in 2025. In Turtle Creek TC-10 remained "similar to reference," and in Creek 705 both 705-05 and 705-10 improved to "similar to reference" from "mildly divergent" in 2024. Site FC-01 was classified as "mildly divergent" in 2025 after being "similar to reference" in 2024. Although metrics such as EPT proportions and richness were generally comparable between impact and control sites, BEAST classifications continued to shift from year to year at both groups of sites, including the control sites. This indicates that the BEAST model classifications do not fully align with the stability suggested by other benthic metrics and highlights the inherent variability present in the dataset.

TABLE 6.3-4 RESULTS OF BEAST ANALYSIS, AND BASELINE (2017, 2021, AND 2022, CONSTRUCTION (2023 AND 2024), AND OPERATIONS (2025)

Site	2025	2024	2023	2022	2021	2017
DC-05	Divergent	Similar to Reference	Similar to Reference	Mildly Divergent	-	-
DC-15	Mildly Divergent	Mildly Divergent	Mildly Divergent	Mildly Divergent	-	-
661-01	Mildly Divergent	Similar to Reference	Highly Divergent	Highly Divergent	-	-
661-05	Similar to Reference	Mildly Divergent	Mildly Divergent	Mildly Divergent	Mildly Divergent	-

Site	2025	2024	2023	2022	2021	2017
661-10	Mildly Divergent	Similar to Reference	Mildly Divergent	Similar to Reference	-	Mildly Divergent
TC-10	Similar to Reference	Similar to Reference	Mildly Divergent	Divergent	-	-
705-05	Similar to Reference	Mildly Divergent	Mildly Divergent	Mildly Divergent	-	Divergent
705-10	Similar to Reference	Mildly Divergent	Divergent	Divergent	-	-
FC-01	Mildly Divergent	Similar to Reference	Highly Divergent	Highly Divergent	-	Mildly Divergent

Most sites showed either consistent classifications from baseline through construction and into operations or moderate year-to-year shifts between "similar to reference" and "mildly divergent," reflecting natural variability. Control sites 661-01 and FC-01 were both classified as "mildly divergent" in 2025, following "similar to reference" classifications in 2024 and "highly divergent" classifications in 2022 and 2023, demonstrating that classification changes are occurring even at sites that are not influenced by the Mine-related activities. Earlier timing of the sampling programs in some baseline and construction years (e.g., 2022 and 2023) may have influenced which benthic invertebrate taxa were present at the time of sampling.

6.3.2 STUDY QUESTION 1—TISSUE METAL COMPARISON TO BASELINE

6.3.2.1 GRAPHICAL ANALYSIS AND COMPARISON TO NUMERIC PERFORMANCE METRICS

Benthic invertebrate tissue metal concentrations presented in this section include those with tissue guidelines (i.e., mercury and selenium) and other metals identified from surface water quality patterns during construction and operations (Section 2.3.1). For most parameters, the 2025 benthic invertebrate tissue metal concentrations were greater than or similar to baseline ranges and were comparable to 2023 and 2024 (construction years) concentrations across sites, with higher concentrations observed at Creek 661 sites relative to Davidson Creek (Figures 6.3-8 to 6.3-17). Appendix D-9 provides the plots of the metals not discussed below. Mean 2025 tissue metal concentrations (Appendix D-8) were evaluated against NPM benchmarks defined as the watershed-specific 95th percentile of baseline and Year 1 of Construction (2023) results (Appendix D-10).

Aluminum, antimony, and arsenic tissue metal concentrations in 2025 were greater than or similar to baseline ranges across sites (Figures 6.3-8 and 6.3-9). The 2025 mean aluminum concentration exceeded the Creek 661 NPM benchmark at 661-05 (2,986 mg/kg), while means at DC-05, DC-15, and 661-10 were below their watershed NPM benchmarks. Antimony exceeded the NPM benchmark at DC-05 (0.089 mg/kg) and at 661-01 (0.15 mg/kg), and arsenic exceeded at 661-10 (10.74 mg/kg; Figures 6.3-8 and 6.3-9; Appendix D-8; Appendix D-10).

Barium concentrations in 2025 were similar to or greater than baseline ranges and were comparable to 2024 at most sites, with some variability at Creek 661 sites. The 2025 mean barium concentration exceeded the Creek 661 NPM benchmark at 661-10 (61.06 mg/kg; Figure 6.3-9; Appendix D-8; Appendix D-10).

Manganese concentrations in 2025 were greater than or similar to baseline ranges, with year-to-year variability across stations. The DC-05 NPM benchmark (969 mg/kg) and 661-10 NPM benchmark (2,473 mg/kg) were exceeded in 2025 (Figure 6.3-13; Appendix D-8; Appendix D-10). However, there are no tissue guidelines for manganese and surface water quality concentrations at those sites were lower than WQG-AL (Section 2.3.3). Manganese in sediments at DC-05 and 661-10 exceeded the SQG-AL however 2025 concentrations were not significantly greater when compared to baseline years (Section 4.4). Thus, no effects on benthic invertebrate communities are expected because of the greater manganese concentrations in benthic invertebrate tissues.

The 2025 cadmium, chromium, copper, lead, nickel, strontium, uranium, and zinc tissue metal concentrations were comparable to or greater than baseline ranges (Figures 6.3-10 to 6.3-12 and 6.3-14 to 6.3-17). The NPM benchmarks for the parameters were not exceeded in 2025, and spatial patterns were consistent with 2024 and baseline tissue metal concentrations (Appendix D-8; Appendix D-10).

The 2025 cobalt, iron, molybdenum, and vanadium tissue metal concentrations were typically within the baseline ranges and 2024 concentrations with some exceptions. Cobalt concentrations exceeded NPM benchmarks at 661-10 (6.40 mg/kg), iron concentrations exceeded at 661-05 (5,920 mg/kg) and 661-10 (6,378 mg/kg), molybdenum concentrations exceeded at DC-05 (1.61 mg/kg) and 661-10 (2.91 mg/kg), and vanadium concentrations exceeded at 661-05 (12.87 mg/kg; Figures 6.3-11, 6.3-12, 6.3-14, 6.3-16; Appendix D-8; Appendix D-10). The surface water concentrations did not exceed WQG-Als at DC-05 (molybdenum), 661-05 (iron and vanadium), and 661-10 (cobalt, iron, and molybdenum) (Section 2.3.3). Similar trends were observed for sediment quality (Section 4.4) suggesting no effects on benthic invertebrate communities are expected.

The 2025 mercury tissue concentrations (as wet weight [wwt]) were variable across sites. The 2025 mean concentration at DC-05 (0.035 mg/kg wwt) exceeded the Davidson Creek NPM benchmark, while mean concentrations at DC-15 and Creek 661 sites remained below watershed NPM benchmarks (Figure 6.3-13; Appendix D-8; Appendix D-10). Selenium concentrations in 2025 were below watershed NPM benchmarks at all monitored sites and were generally lower than 2024 mean concentrations (Figure 6.3-15; Appendix D-8; Appendix D-10).

Although graphical analysis does not suggest Mine-related effects on aluminum concentrations in benthic invertebrate tissues, total aluminum concentrations in surface waters at Davidson Creek and Creek 661 exceeded the WQG-AL in 2025 (Section 2.3.3); therefore, aluminum, along with selenium and mercury, was included in the statistical BACI evaluation.

FIGURE 6.3-8 ALUMINUM AND ANTIMONY CONCENTRATIONS IN BENTHIC INVERTEBRATE TISSUE, BASELINE YEARS (2012, 2017, AND 2022), CONSTRUCTION (2023 AND 2024), AND OPERATIONS (2025)

Notes: Black dotted lines indicate detection limits for zinc (1 mg/kg dwt).
dwt = dry weight
The means +- Standard error and values less than dl replaced with half the dl.

6.3.2.2 BEFORE-AFTER-CONTROL-IMPACT ANALYSIS

Benthic invertebrate tissue metal concentrations in 2024 and 2025 ("after" period) were compared with baseline and Year 1 of Construction conditions ("before" period), represented by 2017, 2021, 2022, and 2023.

The BACI analysis evaluated aluminum concentrations (dry weight), selenium concentrations (dry weight), and mercury concentrations (wet weight; Table 6.3-5). In Davidson Creek, no significant differences between control and impact sites were detected for mercury concentrations ($p_{adjusted}$ = 0.220) or selenium concentrations ($p_{adjusted}$ = 0.220). Aluminum concentrations showed a statistically significant "class:period" interaction, indicating that aluminum concentrations increased at impact sites between the "before" and "after" periods to a greater extent than at control sites ($p_{adjusted}$ = 0.005). In Creek 661, no significant differences between control and impact sites were identified for mercury concentrations ($p_{adjusted}$ = 0.220) or selenium concentrations ($p_{adjusted}$ = 0.498). Aluminum concentrations had a significant "class:period" interaction, with higher "after" period concentrations at impact sites relative to the change observed at control sites ($p_{adjusted}$ = 0.005).

TABLE 6.3-5 BACI ANALYSIS RESULTS FOR BENTHIC INVERTEBRATE TISSUE METAL CONCENTRATIONS

		Impact Watershed	
		Davidson Creek	**Creek 661**
Mercury (wwt)	F-statistic	1.53	1.77
	df	1	1
	Adjusted p-value	0.220	0.220
	Direction	NA	NA
	Effect Size (f2)	0.21	0.08
Selenium (dwt)	F-statistic	2.05	0.46
	df	1	1
	Adjusted p-value	0.220	0.498
	Direction	NA	NA
	Effect Size (f2)	0.03	0.007
Aluminum (dwt)	F-statistic	8.51	0.01
	df	1	1
	Adjusted p-value	0.005	0.005
	Direction	Impact > Control	Impact > Control
	Effect Size (f2)	0.17	0.05

Notes:
df = degrees of freedom; dwt = dry weight; NA=not applicable; wwt = wet weight

The results of the BACI analysis indicates that benthic invertebrate tissue mercury concentrations and selenium concentrations did not differ significantly between control and impact sites during the "after" period in either watershed. The 2024 and 2025 aluminum concentrations were higher at impact sites in both Davidson Creek and Creek 661 when compared to the "before" period. These findings indicate that there are no Mine-related effects for mercury and selenium, while increased aluminum tissue concentrations appear to be a Mine-related influence, consistent with the predicted elevated aluminum concentrations observed in surface waters during construction and operations (Section 2.3.1; Appendix D-11).

6.3.3 STUDY QUESTION 3—TISSUE METAL COMPARISON TO GUIDELINES

The 2025 mean selenium tissue concentrations in benthic invertebrates at all sites were less than the BC tissue guideline (Figure 6.3-15). The 2025 mean mercury tissue concentration was less than the CCME tissue guideline at all sites except for DC-05 (Figure 6.3-13). On a replicate basis, the CCME methylmercury guideline was exceeded in two of the five benthic invertebrate samples at DC-05 (replicates D and E), with measured exceedances of 1.60 and 2.17 times the guideline value (Table 6.3-6). No mercury guideline exceedances occurred in any replicates at site DC-15 or at site 661-05. Selenium concentrations did not exceed the BC interim tissue residue guideline in any samples collected in 2025.

The CCME mercury tissue residue guideline applies specifically to methylmercury (CCME 2022a), and it is conservatively assumed that all measured mercury in aquatic organisms is present in the methylated form. However, published studies indicate that the proportion of methylmercury relative to total mercury in freshwater benthic invertebrates is typically highest in predatory taxa and generally ranges from 70% to 85% (Tremblay 1999). Using these ratios, it is unlikely that methylmercury concentrations in benthic invertebrates at DC-05 exceeded the CCME methylmercury guideline.

[2] 4 mg/kg dry weight (interim guideline)

6.3.4 QUALITY ASSURANCE/QUALITY CONTROL

Three field split samples were collected in 2025 for QA/QC at sites 661-10, DC-05, and FC-01 (Appendix D-7). The RPD was calculated for all tissue metal concentrations. The 2025 RPDs indicate variation between primary and duplicate pairs, with many RPD values exceeding 20% and a large proportion exceeding 50% (Appendix D-7). High RPD values were common across all three split sites, particularly for aluminum, cadmium, cesium, chromium, cobalt concentrations, iron, lead, nickel, strontium, vanadium, and zinc concentrations, where RPD values frequently ranged from 30 to 118%. Only a subset of parameters, often those close to detection limits or with minimal biological variability (e.g., moisture content, some major ions, or low-level trace metals), had RPDs less than 10%. These results indicate that the differences between primary and duplicate samples likely reflect natural variability in benthic invertebrate assemblages, including differences in taxa, life stage, and feeding history within the composite tissue samples, rather than analytical error (Appendix D-7).

One Certificate of Analysis (VA25C5130) was issued for the 2025 benthic invertebrate tissue metals program. All samples were received and analyzed by ALS within required holding times. Laboratory quality control met the required acceptance criteria for all methods used. All method blanks were below analytical detection limits. Laboratory control samples and certified reference materials were within control limits. Precision objectives for laboratory duplicate analyses were met for all evaluated laboratory duplicates, indicating acceptable internal analytical consistency. Overall, the laboratory data quality objectives for accuracy, precision, and contamination were met, and the laboratory report was issued without qualification (Appendix D-7).

6.4 AQUATIC INVERTEBRATE RESPONSE FRAMEWORK

6.4.1 METHODS

The use-protection approach was considered when defining the assessment endpoints for each action level of the Aquatic Invertebrate Response Framework. Abundance is considered appropriate for identifying high-level changes in invertebrate communities. Changes in community composition (family richness, Simpson’s Diversity and Evenness indices, or Bray-Curtis index) can

vary in their ecological significance given the importance of a group as a food resource for fish or other invertebrates or known tolerance of the group to disturbance. Loss of EPT (pollution sensitive taxa) taxa or taxa representing an important fish or other invertebrate food source may result in adverse effects on fish.

Benthic invertebrate measurement endpoints based on abundance and taxonomy (community composition) are included in the aquatic invertebrate response framework. Specifically, the "indicators" described as the NPMs for benthic invertebrates include:

- Benthic invertebrate abundance and community composition (with supporting O:E ratios) used to assess if the Mine-related abiotic components (e.g., nutrient enrichment) are causing a change in aquatic invertebrate numbers;
- Benthic invertebrate family richness and diversity indices (richness, Simpson's Diversity and Simpson's Evenness) used to assess if taxa indicative of healthy communities and habitat are changing as a result of the Mine; and
- The Bray-Curtis Index (similarity index).

Benthic invertebrate tissue metal concentrations are also included in the aquatic invertebrate response framework. Selenium and mercury, which are parameters known to bioaccumulate in the aquatic food chain, can cause adverse effects to higher trophic level organisms if concentrations in benthic invertebrates (as prey items) increase to sufficiently high concentrations. Selenium (dietary guideline of 4 mg/kg dry weight for the protection of fish; Beatty and Russo 2014; BC WLRS 2025a) and methylmercury (0.033 mg/kg wet weight for the protection of wildlife consumers; CCME 2025a) are the only parameters that have guidelines for tissue concentrations in benthic invertebrates.

Spatially, the response levels for aquatic invertebrate tissue metal concentrations were applied to near-field sites only. Any effects of the Mine on aquatic biota are likely to be most apparent at the near-field sites, including:

- Davidson Creek: DC-05 and DC-15; and
- Creek 661: 661-05 and 661-10.

Turtle Creek (TC-05) was not included because the airstrip has not been constructed.

6.4.2 RESULTS

To meet the "none" NPM for aquatic invertebrate communities the following condition is met:

- **[Condition 1]** Benthic invertebrate indicators (abundance and community composition, richness and diversity indices, and Bray-Curtis index) are unchanged from baseline conditions. There is no change in the similarity to reference communities using the reference condition analysis.

For benthic invertebrate community indicators assessed in 2025 (abundance, community composition, and richness and diversity indices), abundance generally increased relative to baseline years, while community composition, richness, diversity, and RIVPACS results remained within the range of values observed during baseline. The Bray-Curtis dissimilarity index values in 2025 were unchanged or lower than baseline conditions most of the monitored sites, although

some sites showed higher dissimilarity relative to baseline, reflecting natural year-to-year variability. Results of the 2025 BEAST analysis ranged from "similar to reference" to "mildly divergent" for most sites, with a "divergent" classification observed at one site. Shifts in BEAST classifications occurred at both control and impact sites, indicating that model classification outcomes were not always consistent with other benthic metrics.

The "none" NPM for aquatic invertebrates was met at all monitored impact sites in Davidson Creek (DC-05 and DC-15) and Creek 661 (661-05 and 661-10).

Elevated cadmium and zinc water and sediment concentrations at Creek 661 sites are attributed to the wildfires in addition to the ore stockpile dust event that occurred in Q1 of 2025. However, the results of the benthic invertebrate community assessment following the event suggested that the communities were not affected. Benthic invertebrate community sampling was also collected at the site immediately downstream of the ore stockpile dust event, 661-04. The 2025 site 661-04 benthic community metrics and comparison to baseline also suggests the dust event did not result in adverse effects to aquatic life (Table 6.4-1).

TABLE 6.4-1 STIE 661-04 BENTHIC INVERTEBRATE COMMUNITY METRICS, 2022, 2023, AND 2025

Metric	2022	2023	2025
Abundance	1,067.5	1,052.5	7,980
Percent EPT	82%	82.4%	74.7%
Richness	27	28	26
Simpson's Diversity	0.91	0.91	0.90
Simpson's Evenness	0.38	0.42	0.37
Bray-Curtis Index[1]	0.76	0.64	0.50
RIVPACS[2]	1.155	1.138	0.995
Beast Analysis	Divergent	Divergent	Similar to Reference

Notes:
[1] Reference mean (± standard deviation) in 2025 = 0.39 ± 0.12
[2] O:E (p > 0.7) = Observed-to-Expected ratio at an expected probability greater than 70%.

To meet the "none" NPM for benthic invertebrate tissue metal concentrations, the annual mean mercury and selenium concentrations in benthic invertebrate tissues must meet the following conditions:

- **[Condition 1]** lower than the tissue residue guideline for selenium or mercury in benthic invertebrate tissue; or
- **[Condition 2]** lower than or equal to the 95th percentile baseline concentration of benthic invertebrate tissue concentrations for selenium and mercury.

In 2025, the mean mercury and selenium concentrations in benthic invertebrates at impact and control sites were below the tissue guideline values except for DC-05 (Section 6.3.3). The mean mercury concentration at DC-05 (0.035 mg/kg wet weight) exceeded both the CCME

methylmercury tissue guideline (0.033 mg/kg wet weight) and the NPM benchmark (0.03 mg/kg wet weight). The 2025 mean selenium concentrations at all monitored sites were lower than the watershed-specific NPM benchmarks, meeting Condition 2 (Section 6.3.3).

Based on these results, the "none" NPM was met for selenium at all sites and for mercury at DC-15 and both Creek 661 sites (661-05 and 661-10). The BACI analysis indicated no significant change in mercury concentrations between impact and control sites relative to baseline conditions (Appendix D-10), meaning that while the guideline and NPM benchmark were exceeded at DC-05, the pattern of change was not statistically different from natural variability. Therefore, the conditions of the "low" action level for mercury were met at DC-05. Although the 2025 mean mercury concentration at DC-05 exceeded both the tissue residue guideline and the NPM benchmark, the lack of statistically significant change from baseline and the absence of increasing trends at both Davidson Creek sites indicate that observed mercury concentrations are not at levels of concern. In addition, the tissue guideline pertains specifically to methylmercury, which typically represents a small fraction of total mercury in benthic invertebrates; therefore, exceedances of total mercury do not necessarily indicate elevated methylmercury exposure. Mercury surface water concentrations in Davidson Creek were within the range observed in baseline years (Section 2.3.1).

6.5 SUMMARY AND RECOMMENDATIONS

The 2025 benthic invertebrate community metrics (abundance, community composition, and richness and diversity indices) were within the range of values observed during baseline at impact sites except for abundance which increased relative to baseline. The Bray-Curtis dissimilarity index values in 2025 were unchanged or lower than baseline conditions at several sites however there were some sites with higher dissimilarity relative to baseline, reflecting natural year-to-year variability. There was also considerable variability in BEAST classifications across both control and impact sites. It is recommended that the next AEMP explore additional or complementary analytical methods to address the natural variability. This may include developing a modified reference envelope composed of sites with habitat characteristics more comparable to Davidson Creek and Creek 661 to improve interpretability. In addition, incorporating replicate sampling at near-field sites in 2026 may help to better characterize within-site variability in benthic community composition and support more robust classification outcomes.

Benthic invertebrate tissue metals in 2025 were generally similar to or greater than baseline, with higher concentrations at Creek 661 consistent with historical patterns. Most metal concentrations were below NPM benchmarks, and exceedances reflected natural variability rather than Mine-related trends. Mercury and selenium tissue concentrations were below guideline and NPM benchmark values at all sites except DC-05, where mercury was slightly higher than the guideline; BACI results showed no significant change from baseline, indicating no Mine-related effect. The significant BACI "class:period" interaction result for total aluminum in benthic tissues was consistent with elevated aluminum in surface waters.

No changes to the benthic invertebrate tissue metal sampling or analyses other than that described in the AEMP Plan, Version 4.0 is recommended.

7. FISH COMMUNITY INVENTORY AND FISH TISSUE METALS

The purpose of the fish community inventory survey is to describe both the structure and fish health of rainbow trout populations within the AEMP study area. The focus is on rainbow trout in the streams nearest to the mine site, as they are the most abundant and widely distributed species during the summer months, with a resident population largely composed of immature individuals.

Two lakes (Tatelkuz and Kuyakuz Lakes) were sampled for fish tissue metals analysis to support the Country Foods Monitoring Program (CFMP). In Tatelkuz Lake, sampling for tissue metals analysis was conducted on rainbow trout, kokanee (*Oncorhynchus nerka*), and mountain whitefish (*Prosopium williamsoni*). In Kuyakuz lake, sampling for tissue metals analysis was conducted on rainbow trout and mountain whitefish.

7.1 MEASUREMENT AND ASSESSMENT ENDPOINTS

Measurement and assessment endpoints have been selected with a focus on non-lethal monitoring of the fish community. The summer fish inventory measurement endpoints consist of an inventory of rainbow trout populations, fish health, and fish tissue metals concentrations (Table 7.1-1).

TABLE 7.1-1 MEASUREMENT AND ASSESSMENT ENDPOINTS FOR THE FISH COMMUNITY SURVEY AND TISSUE METAL SAMPLING

Measurement Endpoint	Assessment Endpoint
Fish inventory	• Catch per unit effort • Fish abundance and density (fish/100 m^2) for each identified species by size/age class
Fish health	• Population structure—length and age • Condition—length and weight
Fish tissue metals concentrations	• Graphical comparison to baseline data • Before-after-control-impact analysis • Comparison to BC or CCME tissue residue guidelines for selenium and mercury (BC WLRS 2025a; CCME 2025d)

Notes:
BC = British Columbia; CCME = Canadian Council of Ministers of the Environment

7.2 SAMPLING SITES AND METHODS

The fish community inventory was conducted at ten stream sites (Figure 7.2-1; Table 7.2-1). These were the same sites where surface water quality monitoring is conducted, thereby providing concurrent water and fish sampling. Fish community inventory surveys were distributed through Creek 661, Creek 705, Turtle Creek, and a Fawnie Creek tributary.

A full description of the methods of the 2025 Fish Community Inventory Program, and the similar Summer Young-of-year/Juvenile Rainbow Trout Program conducted under the federal Follow-up Program (FUP) for Condition 3.14 are provided in the *2025 Rainbow Trout and Fish Community Inventory Report* (Appendix E-1). Fish Community Inventory electrofishing surveys were conducted over a 10-day period from August 6 to September 16, 2025. Specific sampling dates are provided in Table 7.2-1. A description of the survey timing and termination with respect to the AEMP Implementation Framework is also described within the *2025 Rainbow Trout and Fish Community Inventory Report* (Appendix E-1).

The fish tissue metals monitoring program was conducted in conjunction with the fish community inventory monitoring program to assess tissue metal concentrations in rainbow trout within the AEMP streams. Rainbow trout were collected from 11 stream sites to assess tissue metal concentrations (Table 7.2-1). The two AEMP lakes (Tatelkuz and Kuyakuz Lakes; Figure 7.2-1) were also sampled for fish tissue metals analysis to support CFMP monitoring. At Tatelkuz Lake, sampling for tissue metals analysis was conducted on rainbow trout, kokanee, and mountain whitefish. However, only rainbow trout and mountain whitefish were targeted for tissue analyses in Kuyakuz Lake because of the limited kokanee population therein (ERM 2025b).

TABLE 7.2-1 AEMP FISH COMMUNITY INVENTORY STREAM SAMPLING SITES, 2025

7.2.1 FIELD METHODS

7.2.1.1 FISH COMMUNITY INVENTORY

Fish sampling was conducted as close as practical to the surface water quality site, typically within 100 to 200 m. Sites were selected to avoid identified kokanee spawning areas. The fish community inventory surveys commenced in early August to minimize potential impacts to developing rainbow trout embryos.

Fish were collected using a three-pass depletion electrofishing methodology. At each 100-m long electrofishing site, block nets were installed at the upstream and downstream extents to ensure no movement of fish in or out of the sampling area. Sampling began at the downstream block net and ended at the upstream block net and covered the entire stream width. The voltage, duty cycle, and frequency settings were adjusted based on site conditions to maximize efficiency and minimize the risk of injury to fish. If the number of fish caught during the third pass exceeded the number of fish captured from the second pass, then additional passes were conducted in an attempt to reach depletion.

Captured fish were identified to species, enumerated, and measured for length (to the nearest 1 mm) and wet weight (to the nearest 0.1 g). Fish were examined for the presence of markings from previous captures or salvage activities (e.g., adipose fin clips). In preparation for Mine construction, fish were salvaged from portions of Davidson Creek and associated tributaries which fall within the Mine footprint throughout the summers of 2023, 2024, and 2025. Adult and juvenile rainbow trout were marked with adipose fin clips to allow for differentiation of salvaged and resident fish in downstream areas. Rainbow trout fry captured during salvage activities were not fin clipped, due to the potential risk of injury and/or mortality to this small life stage. Salvaged fish were released into various watercourses including Creek 661, Lake 15/16, and Davidson Creek.

Fish were assessed for maturity and categorized as fry (young-of-year), juvenile, or adult, following definitions outlined in the British Columbia Resource Inventory Standards Committee (RISC) standards (RISC 1997). Any deformities, erosion, lesions, and/or tumours (DELTs), parasites, or other anomalies were recorded. Fish were released outside of the enclosed sample site, excluding those that were euthanized for tissue sampling.

Scales were collected from a subset of up to ten rainbow trout per size class at each site for ageing. The subsampled size classes generally correspond to the age classes of rainbow trout (e.g., 81-125 mm [1+], 126-200 mm [2+], 201-275 mm [3+], 276-350 mm [4+], 351-400 mm [5+], and 401-450 mm [6+]), although there is variation on an individual and stream subpopulation level. Scales were not collected from fish less than 80 mm in length.

Observations of beaver dams near sampling locations were recorded and where safe to do so measurements (length, height, width) and distance from sampling location will be recorded.

7.2.1.2 FISH TISSUE METALS

Whole body samples of fish from the creeks were collected for metals analysis with a target sample size of eight rainbow trout per site. Fish were captured via electrofishing, with the exception of TC-05 where baited minnow traps were set overnight.

Tissue samples were also collected from rainbow trout and mountain whitefish captured in Tatelkuz and Kuyakuz lakes. The target sample size was eight fish of each species in each lake. Fish were captured using gillnets. Samples from adult fish collected from lakes were separated into liver (fresh weight was recorded prior to freezing), muscle, and remaining carcass (rest of fish, minus liver and muscle samples). Dissections were conducted using ceramic blades to avoid introducing metals to the tissue during dissection.

For all sacrificed fish, their fork length and weight were recorded, and an ageing structure (otolith) was collected.

All tissue samples for metals analysis were immediately frozen in individually labelled plastic bags before being shipped to ALS (a CALA certified laboratory) for determination of tissue moisture and metal concentration.

7.2.2 LABORATORY ANALYSIS

7.2.2.1 FISH AGING

Age analysis was conducted by North/South Consultants Ltd. in Winnipeg, Manitoba. Aging structures were removed and prepared (e.g., mounted, polished, or otherwise treated) as necessary. Age was determined by counting the number of annuli (i.e., yearly rings) through a compound microscope. Additional details are provided in the *2025 Rainbow Trout and Fish Community Inventory Report* (Appendix E-1).

7.2.2.2 FISH TISSUE METALS

Tissue metal samples were analyzed for percent moisture and total metals at the MDLs consistent with BC ENV (2020).

7.2.3 QUALITY ASSURANCE/QUALITY CONTROL

7.2.3.1 FISH COMMUNITY INVENTORY

Age analysis was conducted by North/South Consultants Ltd. in Winnipeg, Manitoba. Aging structures were removed and prepared (e.g., mounted, polished, or otherwise treated) as necessary. Age was determined by counting the number of annuli (i.e., yearly rings) through a compound microscope. Additional details are provided in the *2025 Rainbow Trout and Fish Community Inventory Report* (Appendix E-1).

7.2.3.2 FISH TISSUE METALS

Laboratory QA/QC practices were consistent with those required by BC ENV (2020a) including the use of certified reference materials (TORT3; lobster hepatopancreas; National Research Council), DORM4 (dogfish protein; National Research Council), and NIST-1566B (oyster tissue; US National Institute of Standards and Technology), and sample replicates.

7.2.4 DATA ANALYSIS

Statistical analyses were performed using R statistical computing package (e.g., R Core Team 2025). Adipose fin clips were used to identify fish that had been previously relocated from upstream watercourses within the Mine footprint. All fish captured with adipose clips were excluded from calculations of assessment endpoints (e.g., CPUE, abundance, density, condition). It should be noted that rainbow trout fry salvaged from the mine site and released into downstream habitats in Davidson Creek in 2023, 2024, and 2025 were not fin clipped, rendering them indistinguishable from resident rainbow trout. It is plausible that relocated (salvaged) fry were recaptured in Davidson Creek during AEMP sampling events; however, without a means of differentiation between salvaged and resident fry, or juveniles in subsequent year if salvaged fry overwintered successfully, it is not possible to remove these potential captures from the dataset.

7.2.4.1 CATCH-PER-UNIT-EFFORT (CPUE)

The CPUE is an index of relative abundance that can be used to compare the abundance of fish populations over time with the assumption that catch is proportional to the amount of effort for each gear-type used. The CPUE was calculated as the number of fish captured per unit time (electrofishing effort) as follows:

*CPUE (fish/100 s) = number of fish caught * [100/ (electrofishing effort)]*

The CPUE was determined for the first electrofishing pass only to allow comparisons with previous surveys that only used a one-pass approach. For effects assessment, a Mann-Kendall temporal trends test was conducted on 1st pass CPUE for sites with more than the minimum of four years of monitoring data.

7.2.4.2 FISH ABUNDANCE AND DENSITY

Abundance was estimated with the Carle-Strub maximum likelihood estimation (MLE) method from removal data (Carle and Strub 1978). This method estimates the true fish abundance (*N*) in a closed site using sequential removal data (e.g., three-pass depletion electrofishing), while avoiding bias and unreliable estimates common with earlier methods. The Carle–Strub likelihood estimate was calculated using the Fisheries Stock Assessment R Package (Ogle et al. 2025; R Core Team 2025).

Fish density was calculated as the number of fish per 100 square metres (fish/100 m^2) based on the abundance estimate and the area sampled at each site. Estimates of abundance and density were calculated for each life-stage (fry, juvenile, adult).

The Carle–Strub MLE provides likelihood-based confidence limits. Standard error and 95% confidence intervals were calculated for both abundance and density estimates.

For effects assessment, a Mann-Kendall temporal trends test will be conducted when four years of monitoring data are available. With only three years of three-pass electrofishing data to date (2023, 2024, and 2025), abundance and density estimates were compared qualitatively.

7.2.4.3 POPULATION STRUCTURE

Population structures of rainbow trout were assessed using length frequency distributions and length-age regressions. Fish captured during three-pass depletion electrofishing effort, as well as fish collected for the analysis of metals concentrations, were included in these analyses. Data from impact sites located in the same watercourse were pooled (e.g., DC-05 and DC-15), and data from regional control sites (FC-01, 705-05 and 705-10) were also pooled prior to analysis. The length frequency distributions between pooled impact and regional control sites were compared using a two-level Kolmorov-Smirnov test. Five individual length measurements were considered the minimum sample size required for the comparison. Comparisons of rainbow trout growth rates between impact sites and regional control sites were evaluated using an analysis of covariance (ANCOVA). Growth rates for the impact watercourses and regional controls were represented by the slope of the length-at-age relationship. Fork length measurements and ageing data were used in the analysis, with fry assigned an age class of zero to allow their inclusion it the dataset.

7.2.4.4 FISH CONDITION

Condition indices provide a comparative measure of the plumpness of fish. Fulton's condition (K) is widely used in fisheries and general fish biology studies (Fulton 1902, 1904; Nash et al. 2006; Ricker 1975) and was calculated according to the following equation:

$$K = \frac{100{,}000 \times W}{L^3}$$

where:

- W = measured fish weight (g) and
- L = measured fish fork length (mm).

Fish captured during three-pass depletion electrofishing effort, as well as fish collected for the analysis of metals concentrations, were included in analyses. Impact and control sites were grouped as described in the previous section.

Fulton's condition was statistically compared between the pooled impact sites for each watercourse and the pooled control sites. Normality of the distributions was first assessed using Anderson-Darling tests. When the data met normality assumptions, a one-way analysis of variance (ANOVA) was used for the comparisons. For datasets that did not meet normality assumptions, a Kruskal-Wallis rank-based test was used.

7.2.4.5 FISH TISSUE METALS ANALYSIS

For tissue metals analysis, summary statistics including minimum, maximum, mean, median, standard deviation, standard error, MDL, sample size, and percent non-detects for dry weight and wet weight tissue metals were calculated for each site, as recommended in BC MOE (2016b). If a concentration is below the MDL, then half the MDL was used during calculations of summary statistics (BC MOE 2016b). Graphical analysis focused on selenium and mercury because tissue residue guidelines have been developed for these parameters (BC WLRS 2025a; CCME 2025d). There were significant increases of total aluminum in Davidson Creek and Creek 661 surface waters that exceeded WQG-AL (Section 2.4) therefore aluminum (in addition to selenium and

mercury) was also included in the graphical analysis and statistical BACI evaluation. The numeric performance benchmark for each site and parameter was calculated as the 95th percentile of tissue concentrations during baseline years and Year 1 of Construction (i.e., 2021, 2022, and 2023). The 2025 mean tissue metal concentration was compared to the site-specific numeric performance benchmark.

Study Question 1—Tissue Metal Comparison to Baseline

A BACI statistical analysis was performed on fish tissue metals for Davidson Creek and Creek 661 watersheds and for each fish species-tissue type collected from the lakes. The BACI analysis for fish tissue metal concentrations introduces a class effect to a mixed model ANOVA, which is based on the classification of a site as an impact or a control site. The "control" sites included the regional control sites FC-01, 705-05, and 705-10 for both watersheds, and 661-01 for sites in the Creek 661 watershed. The "control" site for lake fish species-tissue was KL-01 and "impact" site was TL-01. The "impact" sites for the watershed comparisons were DC-05 and DC-15 in the Davidson Creek watershed, and 661-05, and 661-10 in the Creek 661 watershed. A random effect of year to account for variability in tissue metal concentration was also included. Age was also included as a random effect for the comparison of the lake fish tissue metals to control for differences in growth rates of fish among the two lakes. The "before" period was the data collected in baseline (2017 and 2022) and Year 1 of Construction (2023). The Year 1 of Construction (2023) was added to the "before" period because there were limited construction activities and no surface water discharge in 2023 (ERM 2025b). The "after" period was data collected in 2024 and 2025.

The BACI analyses tested the hypothesis that if mine activities affected fish tissue metals, the expectation would be a significant change in tissue metal concentration at impact sites in comparison with baseline concentrations not observed at control sites. If both impact and control sites experienced a parallel change over time, then it would be likely a change over a larger spatial scale affected all control and impact sites, and it is unlikely that construction activities affected benthic invertebrate tissue metals.

Analysis was performed using the most recent R statistical computing package (R Core Team 2024). Data transformations (e.g., log transformation) were completed if determined to be appropriate (e.g., to achieve random distribution of residuals).

The interaction between the period ("before" or "after") and class (impact or control) effects would indicate whether any before-after change in the mean tissue metal concentration occurred in the impact site also occurred in the control site(s). The overall site (control versus impact) and period ("before" versus "after") interaction significance (p-value less than significance level (α) of 0.05) was assessed using an F test. To reduce the number of false positives (Type I error) due to the large number of statistical tests conducted, multiple test correction was applied.

The analysis was completed for mercury and selenium because there is a tissue residue guideline (BC WLRS 2025a; CCME 2025d). There were significant increases of total aluminum in Davidson Creek and Creek 661 surface waters that exceeded WQG-AL (Section 2.4) therefore aluminum (in addition to selenium and mercury) was included in the statistical BACI evaluation for rainbow trout tissue collected from those watersheds.

Study Question 3—Tissue Metal Comparison to Guidelines

Tissue metal concentrations were compared to established BC and CCME tissue guidelines as indicated in Table 7.2-2 (BC WLRS 2025a; CCME 2025d). For the purposes of this comparison, measurements of total mercury in fish tissue samples were assumed to be 100% methylmercury. For fish, it is typically assumed that nearly 100% of the total mercury concentration is in the form of methylmercury (Health Canada 2007), although the proportion of methylmercury will likely be less than 100% (CCME 2000). Bloom (1992) indicates that the proportion of methylmercury relative to total mercury is at least 95%, and states that "virtually all" of the mercury is in the methylmercury form in fish tissues. While actual concentrations of methylmercury are likely to be slightly less than the total concentration, this assumption ensures that the estimates of methylmercury in fish tissues from total mercury concentrations was conservative.

TABLE 7.2-2 TISSUE METAL GUIDELINES FOR THE PROTECTION OF WILDLIFE CONSUMERS OF AQUATIC BIOTA

Parameter	Source	Guideline Type	Guideline Value
Mercury (methylmercury)	CCME (2025d), BC WLRS (2025a)	Protection of wildlife consumers of aquatic resources	0.033 mg/kg wwt
Selenium	BC WLRS (2025a)	Protection of aquatic health	4 mg/kg dwt

Notes: BC WLRS = BC Ministry of Water, Land and Resource Stewardship; CCME = Canadian Council of Ministers of the Environment; dwt = dry weight; wwt = wet weight

Quality Assurance/Quality Control

Laboratory QA/QC included evaluation of laboratory duplicates, certified reference material spikes, laboratory control samples, and method blanks. An RPD of less than 20% is considered acceptable when the concentrations of the two samples are greater than five times the MDL. A higher RPD is acceptable when concentrations are lower (BC ENV 2013), but caution should be used in interpretation of near MDL concentrations.

7.2.5 EXCEPTIONS TO METHODS

Table 7.2-3 provides a summary of the exceptions from the proposed sampling methods indicated in the AEMP Plan (ERM 2025b).

TABLE 7.2-3 SUMMARY OF EXCEPTIONS TO METHODS 2025 FISH COMMUNITY INVENTORY AND TISSUE METAL SAMPLING

Methods Indicated in AEMP Plan Version 4.0	Methods Conducted in 2025
Tissue metals samples will be collected from rainbow trout, kokanee, and mountain whitefish in Tatelkuz Lake. The target sample size is eight fish of each species.	No kokanee were captured during Tatelkuz Lake sampling despite extensive gillnetting, angling, and hoop netting efforts.

Methods Indicated in AEMP Plan Version 4.0	Methods Conducted in 2025
Tissue metals samples will be collected from eight euthanized rainbow trout per site.	No fish were captured at TC-01 (Turtle Creek). No fish were captured at 661-01 (Creek 661). Water levels were extremely low resulting in disconnected sections of wetted channel and very limited connectivity to downstream habitats. Only three rainbow trout were submitted for tissue metals analysis at site TC-05 (Turtle Creek); one rainbow trout was captured via minnow trapping and two were captured via open-site backpack electrofishing. Only seven rainbow trout were submitted for tissue metals analysis at site 661-05; three rainbow trout were captured during the three-pass depletion survey. Additional electrofishing efforts downstream of the survey site resulted in the capture of four additional rainbow trout.
Fish will be collected using closed-site backpack electrofishing with block nets.	The three-pass electrofishing survey was not conducted at TC-05 (Turtle Creek) as beaver dam impoundments and water depths over 1.5 m impacted practicality of this sampling methodology.

7.3 RESULTS AND DISCUSSION

Results of the 2025 AEMP Fish Community Inventory program, and the similar Summer Young-of-Year/Juvenile Rainbow Trout Program conducted under the FUP for Condition 3.14, are provided in the *2025 Rainbow Trout and Fish Community Inventory Report* (Appendix E-1). The site and survey information, field water quality data, fish sampling effort, individual fish data (including Fulton's conditions and fish aging results), and beaver dam observations are provided within the appendices of that report.

A total of 1,838 rainbow trout were captured in the AEMP streams (93 were excluded from data analysis due to the presence of adipose fin clips). No other species were captured. A total of 178 fish mortalities were observed during sampling, including rainbow trout euthanized for metals analysis. The number of mortalities detailed by site, species, and cause are provided in the *2025 Rainbow Trout and Fish Community Inventory Report* (Appendix E-1).

7.3.1 FISH COMMUNITY INVENTORY

7.3.1.1 CATCH-PER-UNIT-EFFORT

In 2025, rainbow trout were the only species captured at all stream sites, except for sites TC-01 and 661-01 where no fish were captured. Electrofishing 1st pass CPUE ranged from 0 to 16.51 fish/100 seconds (Table 7.3-1). Generally, 1st pass CPUE was higher in 2025 than in any other year at impact site DC-05, as well as the regional control sites (FC-01, 705-05 and 705-10) (Figure 7.3-1). Trend analyses of 1st pass CPUE, via a Mann-Kendall test, did not find a significant temporal trend at any site (Appendix E-5). First pass CPUEs were greater in 2024 and 2025 at most sites compared to earlier sampling years. These increases may partly reflect changes in sampling efficiency associated with a change in consultants conducting the sampling, rather than changes in the relative abundance of rainbow trout. Electrofishing success is sensitive to crew experience, gear settings, and netting efficiency, among other variables, even when standard protocols are followed.

FIGURE 7.3-1 FIRST PASS ELECTROFISHING CPUE, 2011 TO 2025

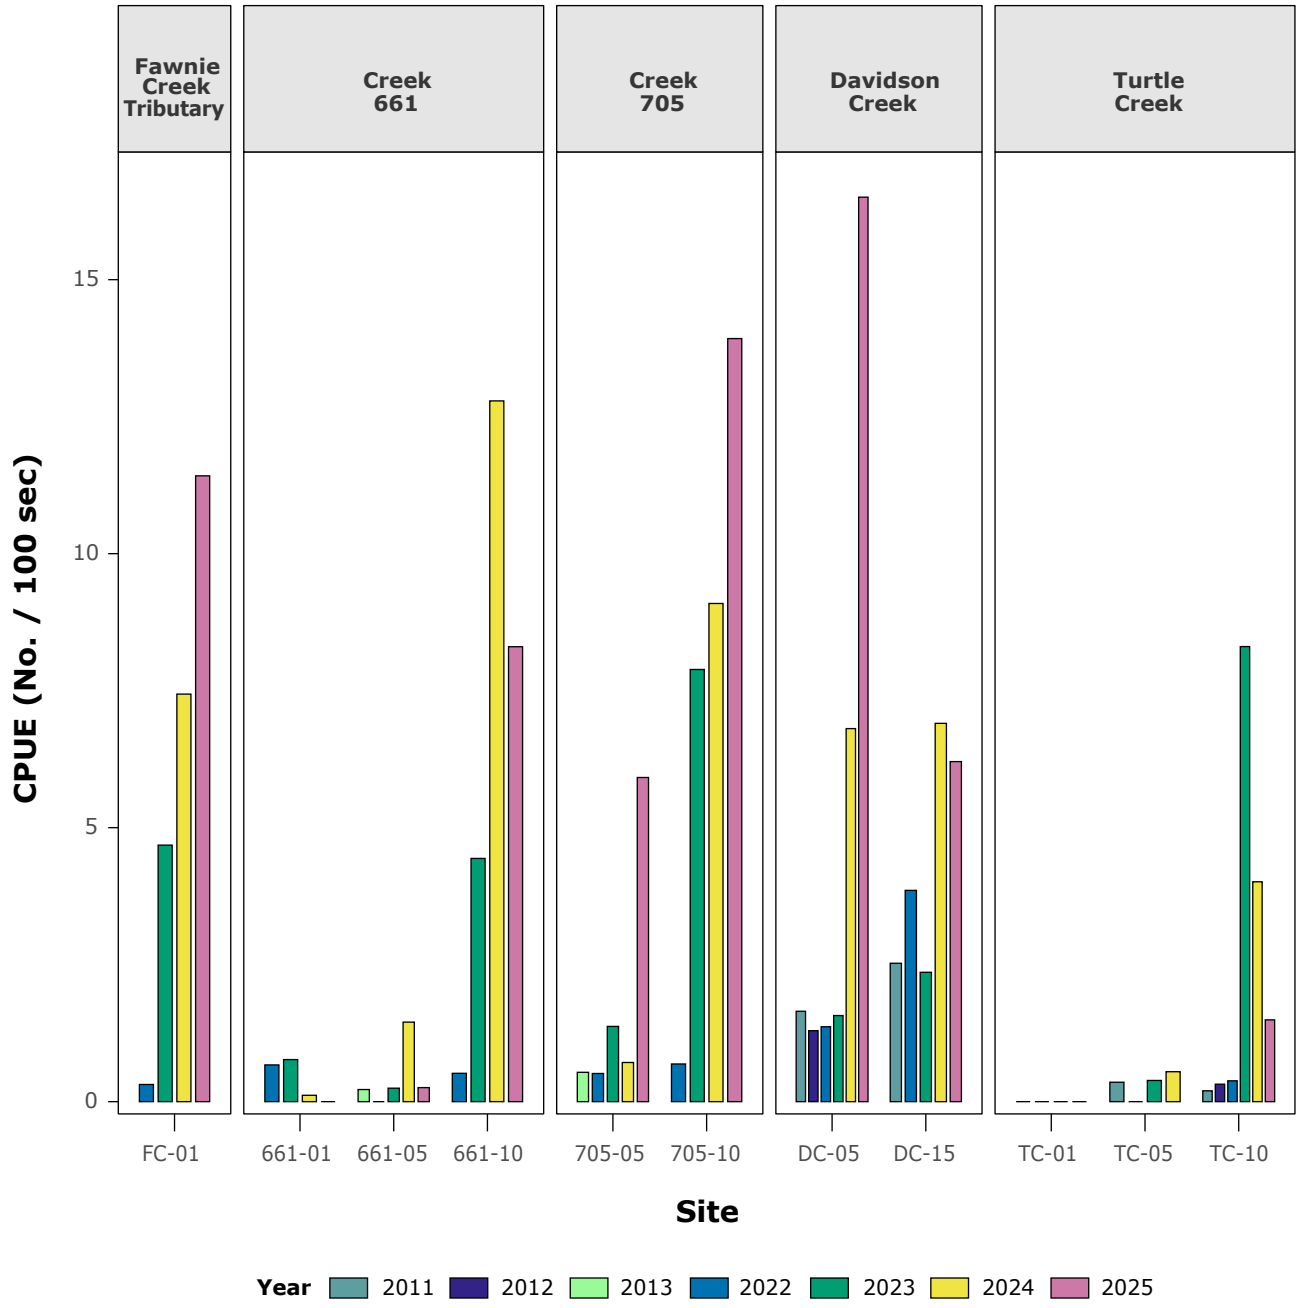

TABLE 7.3-1 FIRST PASS ELECTROFISHING CATCH-PER-UNIT-EFFORT, 2025

Site	Site Type	First Pass CPUE (No. Fish/100 s)
705-05	Regional Control	5.92
705-10	Regional Control	13.92
FC-01	Regional Control	11.42
DC-05	Impact	16.51
DC-15	Impact	6.21
661-01	Control	0
661-05	Impact	0.26
661-10	Impact	8.30
TC-01	Control	0
TC-05	Impact	-
TC-10	Impact	1.49

7.3.1.2 ABUNDANCE AND DENSITY

Abundance estimates of rainbow trout fry and juveniles for 2023 through 2025 are shown in Figure 7.3-2 and Figure 7.3-3 with 95% confidence intervals (back transformed from log data). Density estimates (with 95% confidence intervals) of both life stages are presented in Figure 7.3-4 and Figure 7.3-5. Estimates, standard error, and confidence interval values are also provided in tabular format in Appendix E-5. It should be noted that sequential electrofishing passes were conducted to achieve depletion across the total catch, not individual life stages or size classes. Consequently, applying the Carle-Strub model to life stage, or size-class, may lead to error, because catch numbers by stage or size did increase between passes at some sites. Partitioning the data by size class led to more errors than partitioning by life stage; therefore, abundance and density estimates by life stage are presented below.

Estimates could not be determined when insufficient number of fish were captured in a specific life stage. When the Carle-Strub model produced an abundance estimate that fell on the lower boundary of the model, the model concluded that the number of fish present was equal to the number of fish captured. Although the model flagged violations for some results due to rising catch numbers in successive passes, life stage specific abundance and density estimates were generated. These estimates may not be accurate.

In Creek 705, at both regional control sites 705-05 and 705-10, abundance and density of both fry and juveniles were higher in 2025 than both previous years. At regional control site FC-01, abundance and density estimates of both fry and juveniles have increased year over year since 2023. Methodological factors that may influence capture efficiency, as well as the survey being undertaken by different consultants in 2024, could account for these differences.

FIGURE 7.3-2 ABUNDANCE ESTIMATES OF RAINBOW TROUT FRY, 2023 TO 2025

N = number of fish.

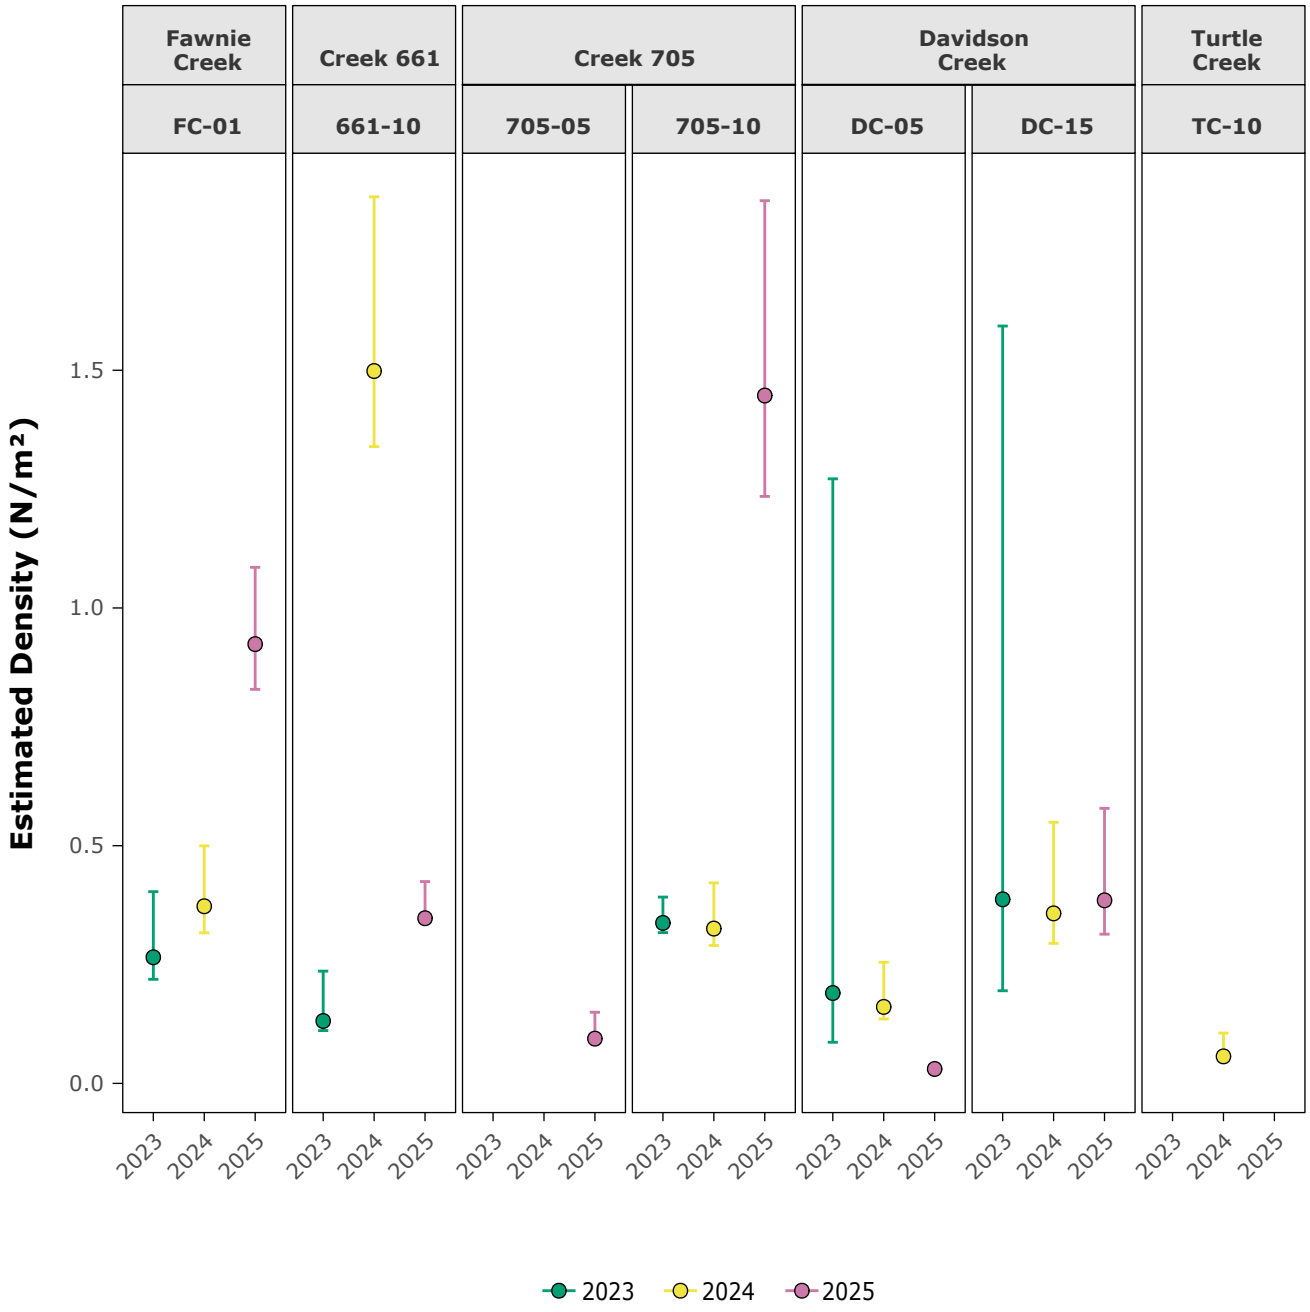
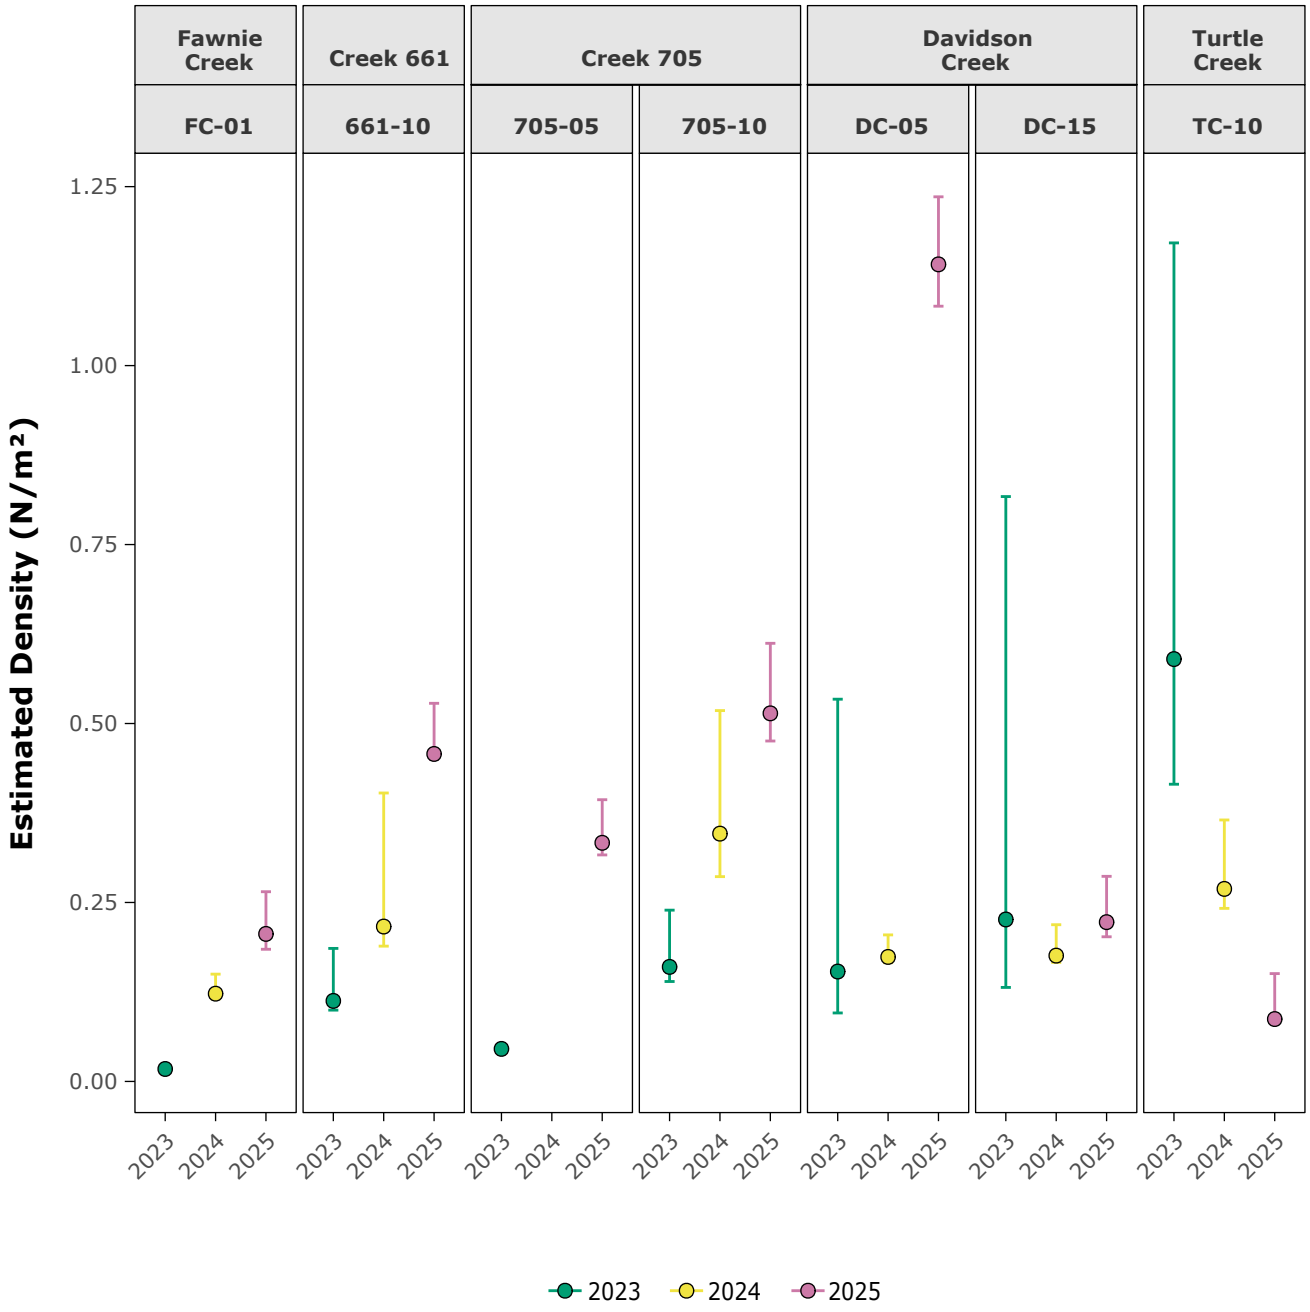
FIGURE 7.3-4 DENSITY OF RAINBOW TROUT FRY, 2023 TO 2025



Notes: Error bars represent the 95% confidence intervals.
N = number of fish.

FIGURE 7.3-5 DENSITY ESTIMATES OF JUVENILE RAINBOW TROUT, 2023 TO 2025



Notes: Error bars represent the 95% confidence intervals.
N = number of fish.

The greater abundance and density estimate of juvenile rainbow trout at DC-05, as well as 1st pass CPUE results (see previous section), in 2025 may be explained by fish salvage operations related to the Mine construction activities. While salvaged juvenile and adult fish were marked with adipose clips (and were excluded from analyses), unmarked salvaged fry were relocated to the Davidson Creek mainstem from 2023 to 2025. As these unmarked fish were indistinguishable from resident fish during sampling, it is plausible that the abundance and density estimates represent a mixture of resident and relocated individuals rather than the naturally occurring population alone.

Sampling in 2023 occurred before the majority (approximately 80%) of salvaged fish from that year were released, reducing the likelihood that relocated fish influenced the 2023 estimates. Sampling in 2024 and 2025 occurred during the fish salvage timeframe. In August 2024, during site preparation works associated with the construction of the FWR, a drop structure, limiting upstream fish passage, was installed approximately 100 m upstream of the upstream extent of the DC-05 site. Additionally, in late July 2025, during fish salvage works associated with the construction of the FWR, a large fish exclusion fence was installed approximately 50 m upstream of the DC-05 site. The DC-05 area effectively became the upstream limit of the fish-bearing portion of Davidson Creek in 2025. It is plausible that the higher abundances observed in 2025 were the result of fish, primarily juveniles, holding in the area as they attempted to disperse upstream. Additionally, fish salvage operations were ongoing during the 2025 sampling period and fish salvaged from upper reaches of Davidson Creek were released immediately upstream of the DC-05 site, as evidenced by the 93 adipose-clipped fish captured during sampling (15.6% of total captures).

In Creek 661, fry have not been captured at sites 661-01 and 661-05, across all sampling years, suggesting limited spawning or spawning success near these sites. Catch rates of juveniles at both 661-01 and 661-05 have been very low in all sampling years. When total catch is low, even small deviations (such as a single fish evading capture) can disproportionately influence depletion patterns and inflate or depress the model outputs. Low catch also reduces the ability to demonstrate true depletion across passes and produces wide confidence intervals that obscure real year-to-year differences. Consequently, abundance and density estimates for sites 661-01 and 661-05 should be viewed with caution. At site 661-10, abundance and density estimates of fry were notably greater in 2024, with estimates in 2025 similar to those in 2023.

7.3.1.3 POPULATION STRUCTURE

Across all AEMP fish community inventory sites, rainbow trout fry fork length ranged from 24 to 57 mm and weight ranged from 0.1 to 2.1 g. Juvenile fork length ranged from 58 to 171 mm and weight ranged 1.9 to 65.2 g. Length-frequency distributions were generated for each site (Figure 7.3-6). At most sites, 0 and 1^+ age cohorts were evident; however, older age classes were less distinct. In 2025, significant differences were detected in length frequency distributions between Davidson Creek and the regional controls ($p < 0.001$), between Creek 661 and the regional controls ($p < 0.001$), and between Turtle Creek and the regional controls ($p < 0.001$) (Figure 7.3-7; Appendix E-5). Significant differences were also observed in 2024 and 2023.

FIGURE 7.3-6 LENGTH-FREQUENCY DISTRIBUTIONS FOR RAINBOW TROUT, 2025

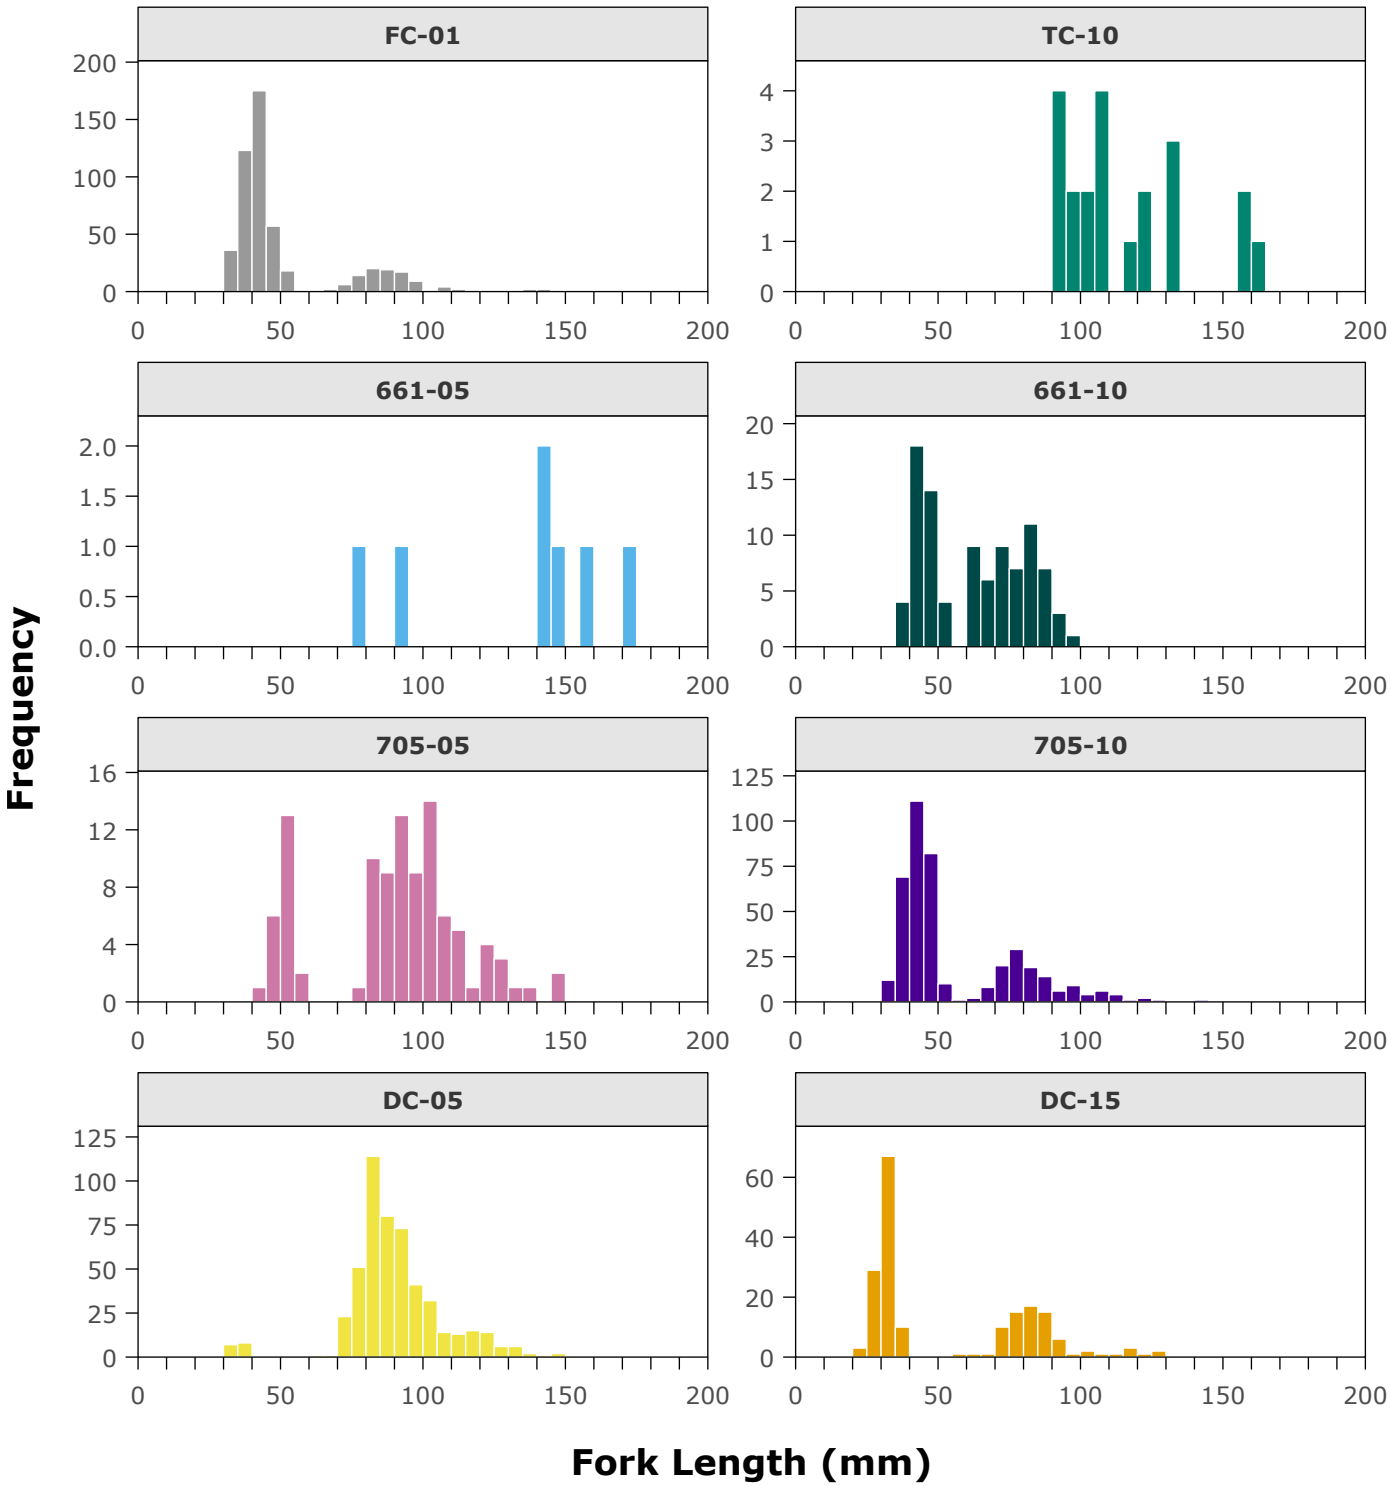


FIGURE 7.3-7 LENGTH-FREQUENCY DISTRIBUTIONS AND CUMULATIVE LENGTH-FREQUENCY FOR RAINBOW TROUT AT REGIONAL CONTROL AND IMPACT SITES, 2025

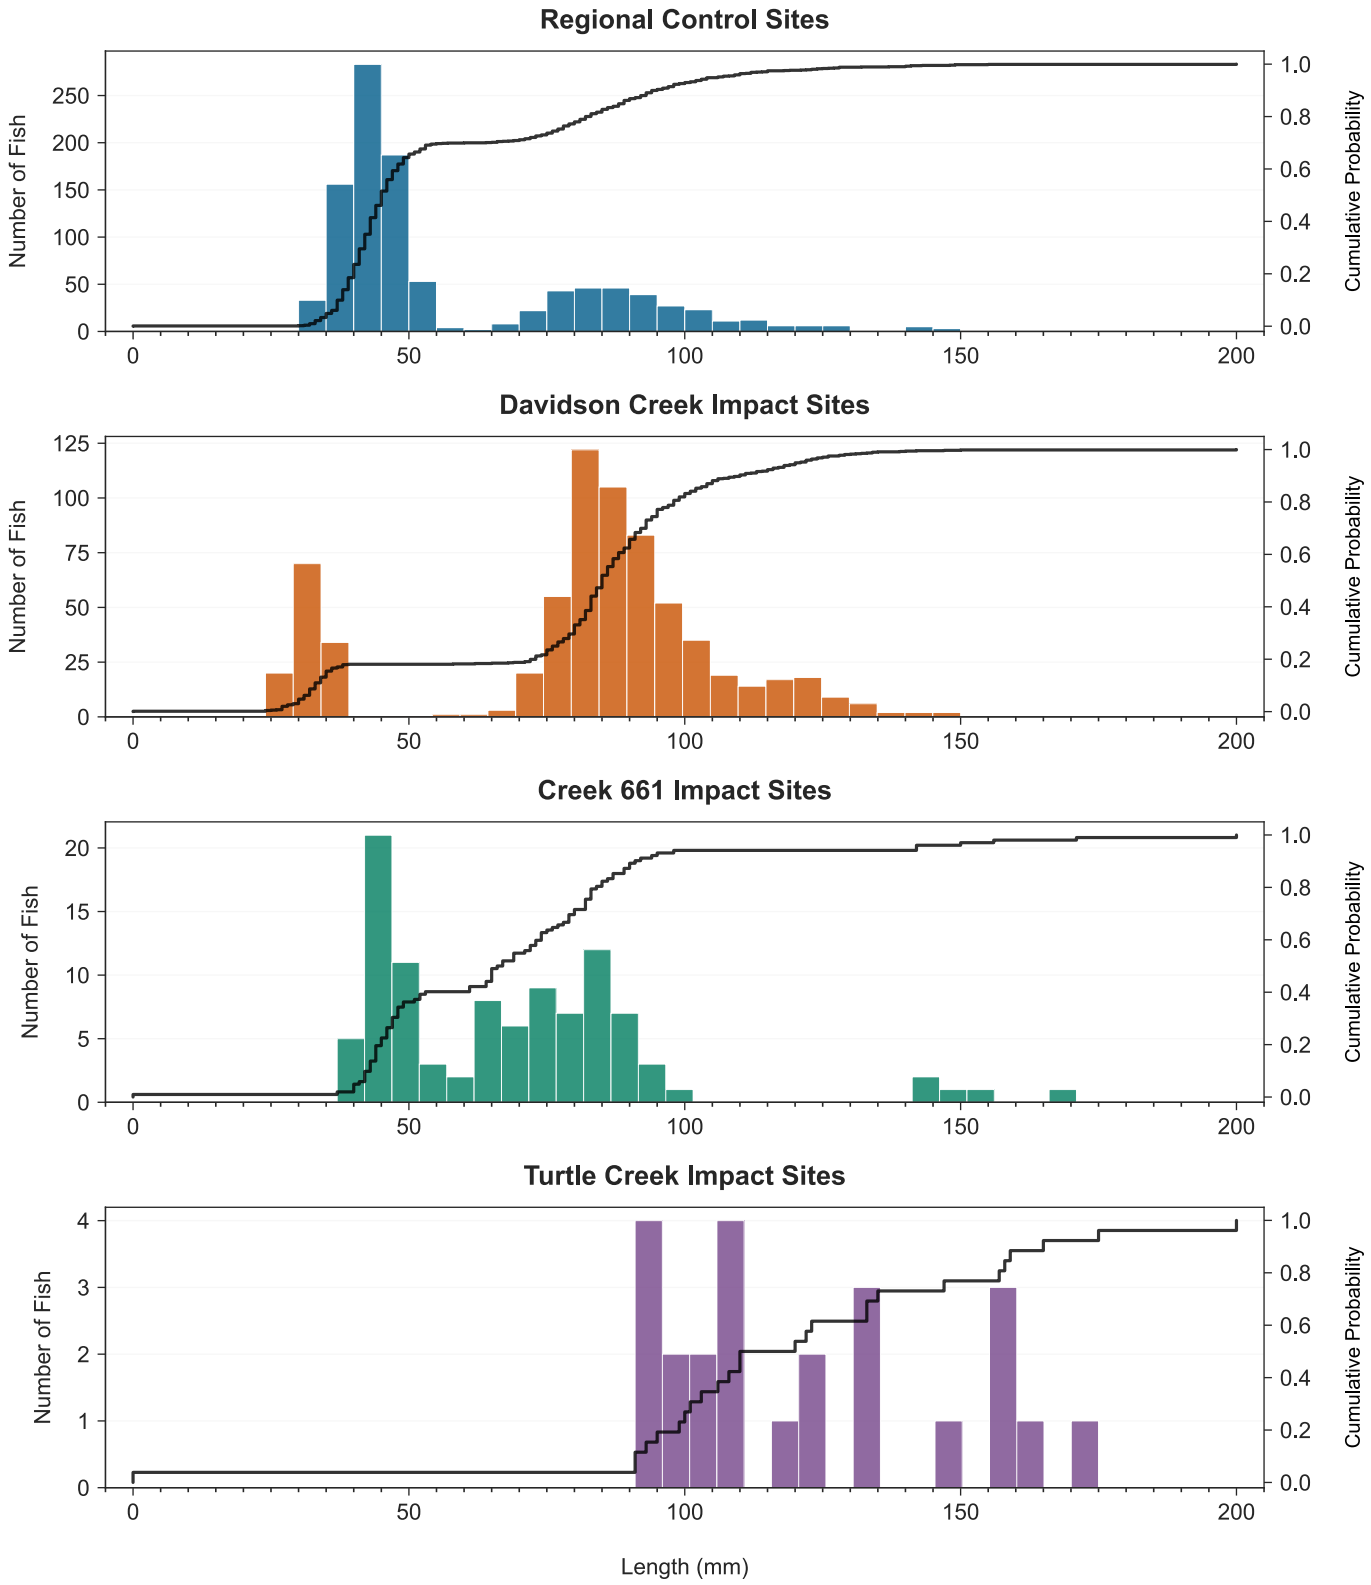

Notes: Regional Control Sites include sites 705-05, 705-10, and FC-10.

Length-age linear regressions for rainbow trout captured at impact sites in Davidson Creek, Creek 661, and Turtle Creek, as well as at the regional control sites, are shown in Figure 7.3-8. Comparison of regression slopes found that growth rates of rainbow trout were significantly different between each of the impact creeks and the regional controls (Table 7.3-2). Results of the statistical comparisons are presented Appendix E-5.

TABLE 7.3-2 LENGTH AT AGE STATISTICAL COMPARISONS WITH REGIONAL CONTROL SITES (705-05, 705-10, FC-01), 2023 TO 2025

Impact Sites	Year	Regional Control Sites	
		p	**Significance**
Davidson Creek (DC-05, DC-15)	2023	0.002	Yes
	2024	0.880	No
	2025	<0.001	Yes
Creek 661 (661-05, 661-10)	2023	0.998	No
	2024	0.148	No
	2025	0.030	Yes
Turtle Creek (TC-05, TC-10)	2023	<0.001	Yes
	2024	0.003	Yes
	2025	0.037	Yes

7.3.1.4 FISH CONDITION

Fulton's condition factor serves as a direct indicator of a fish's energy reserves by assessing its weight-to-length relationship. Individuals exhibiting greater weight for a given length are interpreted as having higher energy stores, and values exceeding one typically denote fish in good condition. Mean condition, by life stage, of rainbow trout in regional control sites and impact sites in Davidson Creek, Creek 661 and Turtle Creek are presented in Figure 7.3-9 and Table 7.3-3; Mean condition of fish at each individual site are provided in Appendix E-5.

Both fry and juveniles in Davidson Creek and Creek 661 exhibited greater condition than fish in the regional control sites (Table 7.3-4). No difference in condition was found between juveniles in Turtle Creek and those in the regional control sites. These differences are not considered ecologically significant, as condition values remained within two standard deviations of the regional control mean (a statistic used to describe what is called the normal range of a population).

7.3.2 FISH TISSUE METALS

Eight rainbow trout were collected at each stream site for fish tissue metals analysis, except at 661-05 (seven rainbow trout were captured), TC-05 (three rainbow trout were captured) and no fish were captured at TC-01 and 661-01. Beaver dam impoundments and water depths over 1.5 m impacted practicality of three-pass electrofishing survey at TC-05 with only two rainbow trout captured via electrofishing. Minnow trapping effort captured one additional rainbow trout at TC-05 with 3 of 8 (sample size target) rainbow trout submitted for metals analysis. No fish were captured at TC-01 (Turtle Creek) and 661-01 (Creek 661) during the three-pass electrofishing survey. Additional electrofishing effort was undertaken both upstream and downstream, and resulted in no fish captures. Water levels were extremely low and not conducive to other sampling methodologies (e.g., minnow trapping).

At the lake sites, eight mountain whitefish and eight rainbow trout were collected from both Tatelkuz and Kuyakuz lakes for fish tissue metals analysis. No Kokanee were captured despite extensive gillnetting, angling, and hoop netting efforts.

Fish tissue metals laboratory analysis results for fish collected from streams are provided in Appendix E-6, laboratory results of fish collected from lakes are provided in Appendix E-7, and summary statistics by site are provided in Appendix E-8.

7.3.2.1 STUDY QUESTION 1—TISSUE METAL COMPARISON TO BASELINE

Streams

There were no benthic invertebrate tissues metals that increased as a result of construction and operation activities, except for mercury concentrations at DC-05 (Section 6.3.2). However, there were significant increases of total aluminum in Davidson Creek and Creek 661 that exceeded WQG-AL (Section 2.3) therefore aluminum, selenium and mercury are discussed below. All other fish tissue metals were plotted and provided in Appendix E-9. Site-specific NPM benchmarks are provided in Appendix E-10.

Summary statistics of all tissue metals in rainbow trout collected at Turtle Creek sites are provided in Appendix E-8, however they are not discussed further because the airstrip has not been constructed.

Aluminum concentrations in rainbow trout whole-body tissue at Davidson Creek and Creek 661 were lower in 2025 than baseline years (2021 and 2022) and was similar or slightly higher than concentrations observed during construction years (2023 and 2024; Figure 7.3-10). Mean 2025 aluminum concentrations at impact sites (99.8 mg/kg at DC-05, 79.1 mg/kg at DC-15, 13.7 mg/kg at 661-05, and 15.8 mg/kg at 661-10) were below their site-specific NPM benchmarks (Appendix E-8 and Appendix E-10).

The 2025 mercury concentrations in rainbow trout whole-body tissue at Davidson Creek and site 661-05 in Creek 661 was similar to or lower than baseline and construction period concentrations (Figure 7.3-11). The 2025 mercury concentration at site 661-10 was higher than baseline and/or construction period concentrations but was within the range of the control sites (Figure 7.3-11). Mean 2025 mercury concentrations at impact sites (0.0752 mg/kg wwt at DC-05, 0.0837 mg/kg wwt at DC-15, 0.0819 mg/kg wwt at 661-05, and 0.0909 mg/kg wwt at 661-10) were below site-specific NPM benchmarks (Appendix E-8 and Appendix E-10).

Selenium concentrations in rainbow trout collected at Davidson Creek and Creek 661 in 2025 were similar to or lower than baseline years and comparable to construction years, with similar patterns at control sites (Figure 7.3-12). Mean 2025 selenium concentrations (1.85 mg/kg at DC-05, 1.71 mg/kg at DC-15, 2.91 mg/kg at 661-05, and 0.87 mg/kg at 661-10) were below their site-specific NPM benchmarks (Appendix E-8 and Appendix E-10).

Black dotted line is the selenium detection limit 0.02 mg/kg dwt.

Lakes

Mercury concentrations in fish tissue samples in 2025 were higher in fish collected from Tatelkuz Lake (impact) compared to Kuyakuz Lake (control) across all tissue types (Figure 7.3-13). Similar to previous years, mercury concentrations in liver tissues were greater than concentrations measure in other tissue types (Figure 7.3-13). At both lakes, lower concentrations were observed during the construction (2023 and 2024) and operations years (2025) when compared with baseline years (2021 and 2022). Therefore, the greater mercury concentrations in Tatelkuz Lake fish tissues (impact) compared to Kuyakuz Lake fish tissues (control) are not related to construction or operation activities.

Selenium concentrations in 2025 for all tissue types in mountain whitefish and rainbow trout were higher in fish collected from Tatelkuz Lake than Kuyakuz Lake (Figure 7.3-14). Selenium concentrations in carcass/viscera, muscle, and liver tissues in 2025 were similar to concentrations observed during baseline and construction years (Figure 7.3-14). Similar to previous years, liver tissues selenium concentrations were greater than concentrations measured in muscle and carcass/viscera tissues. Therefore, the greater selenium concentrations in Tatelkuz Lake fish tissues (impact) compared to Kuyakuz Lake fish tissues (control) are not related to construction or operation activities.

7.3.2.2 BEFORE-AFTER-CONTROL-IMPACT ANALYSIS

The results of the BACI analyses are provided in Appendix E-11 and Appendix E-12 and summarized in Table 7.3-5. Power analyses indicated that detectable effect sizes (f^2) for the 2025 models ranged from approximately 0.04 to 4.36, depending on parameter, tissue type, and species. Consistent with previous reporting, 2023 continued to be included in the "before" period based on similarity in tissue metal concentrations between 2021, 2022, and 2023 at both control and impact sites.

Streams

In Davidson Creek, BACI analysis indicated no statistically significant differences between control and impact sites for mercury ($p_{adjusted}$ = 0.0803), selenium ($p_{adjusted}$ = 0.0803), and aluminum ($p_{adjusted}$ = 0.763) concentrations in rainbow trout whole fish samples (Table 7.3-5). At Creek 661, BACI analysis indicated no significant differences in mercury ($p_{adjusted}$ = 0.377) and selenium ($p_{adjusted}$ = 0.0324) concentrations in rainbow trout whole fish samples (Table 7.3-5). Aluminum concentrations were statistically significant different ($p_{adjusted}$ = 0.0008), during the "after" period when compared to "before" period. However, the concentrations of aluminum in whole fish samples decreased in Creek 661 (impact) sites between the "before" and "after" periods while tissue concentrations collected from control sites were similar between the two periods. Therefore, statistical analysis confirms that no Mine-related effects occurred in rainbow trout tissues collected from stream sites in 2025.

FIGURE 7.3-8 MERCURY CONCENTRATION IN CARCASS/VISCERA, MUSCLE, AND LIVER TISSUES FROM KOKANEE, MOUNTAIN WHITEFISH, AND RAINBOW TROUT IN KUYAKUZ AND TATELKUZ LAKES, BASELINE (2021 AND 2022), CONSTRUCTION (2023 AND 2024), AND OPERATIONS (2025)

Notes:
df = degrees of freedom; dwt = dry weight; NA = not applicable; NC = not completed; wwt = wet weight

Lakes

There were no statistically significant differences in mercury and selenium concentrations in any fish tissue types collected from Tatelkuz Lake (impact site) compared to Kuyakuz Lake (control site; all $p_{adjusted} \geq 0.579$; Table 7.3-5). Including fish age as a covariate in statistical analyses of mercury and selenium fish tissue concentrations aided in removing the confounding variation in tissue concentrations attributed to fish sizes between the two lakes, where older fish typically bioaccumulate these metals more than rapidly growing fish. No BACI analyses were completed for Kokanee as they were not sampled in 2025. Overall, the BACI results indicate no evidence of Mine-related effects on fish tissue metal concentrations in lake sites in 2025.

7.3.2.3 STUDY QUESTION 3—TISSUE METAL COMPARISON TO GUIDELINES

The 2025 fish tissue samples collected at stream sites frequently exceeded the mercury tissue residue guideline for the protection of wildlife consumers of aquatic resources (0.033 mg/kg wwt) at both impact and control sites (Table 7.3-6). Whole-body rainbow trout exceedances occurred at DC-05 (8 of 8), DC-15 (8 of 8), 661-05 (7 of 7), 661-10 (8 of 8), 705-05 (8 of 8), and 705-10 (7 of 8); no exceedances occurred at FC-01. The 2025 rainbow trout whole-body mean selenium tissue concentration was less than the selenium guideline (4 mg/kg dwt) in at stream sites (Table 7.3-6).

At lake sites, 2025 tissue results showed no mercury exceedances at Kuyakuz Lake (KL-01) for either rainbow trout or mountain whitefish in carcass/viscera or muscle tissues (0 of 8 in both tissues for both species; Table 7.3-6). At Tatelkuz Lake (TL-01), exceedances occurred for mountain whitefish and rainbow trout: mountain whitefish had 3 of 8 exceedances in carcass/viscera and 6 of 8 in muscle, and rainbow trout had 4 of 8 in carcass/viscera and 4 of 8 in muscle (Table 7.3-6). There were no selenium guideline exceedances in fish collected from the lakes in 2025.

Overall, mean mercury tissue concentrations in 2025 exceeded the guideline at both impact and control sites for multiple tissue types (at lake sites). This pattern was consistent with baseline conditions and indicates no evidence of regional or construction-related effects (Figures 7.3-6 and 7.3-8).

7.3.2.4 QUALITY ASSURANCE/QUALITY CONTROL

The laboratory completed quality control analysis (method blanks, laboratory certified material, and reference material) and results indicated the data quality objectives were met. Twenty-one certificates of analysis were issued for fish tissue metal testing. Samples were received and analyzed by ALS prior to hold time exceedances. All laboratory control samples and reference materials were within the quality control limits, and all method blank concentrations were below the analytical detection limit. Most laboratory replicates met the quality control objectives for precision in batches. Overall, the laboratory data quality objectives for internal QA/QC were met, and the reports were issued and distributed without further comment.

No outliers were identified in Q-Q plots completed for statistical analysis.

TABLE 7.3-6 STREAM AND LAKE FREQUENCY OF EXCEEDANCE OF THE FISH TISSUE GUIDELINES, 2025

Species	Site	Site Type (Stream or Lake)	Number of Fish	Frequency of Exceedance [a]			
				Mercury	Selenium		
				Carcass/ Viscera/ Whole Body	Muscle	Carcass/ Viscera/ Whole Body	Muscle
Mountain White Fish	KL-01	Control (lake)	8	0	0	0	0
	TL-01	Impact (lake)	8	3	6	0	0
Rainbow Trout	DC-05	Impact (stream)	8	8	-	0	-
	DC-15	Impact (stream)	8	8	-	0	-
	661-05	Impact (stream)	7	7	-	0	-

7.4 FISH TISSUE RESPONSE FRAMEWORK

7.4.1 METHODS

Parameters included in the fish tissue metal response framework are metals with BC or CCME tissue residue guidelines which are for selenium and mercury (BC WLRS 2025a; CCME 2025d). Including mercury in fish tissue in the adaptive response framework will help to address uncertainties associated with the surface water quality and fish tissue model predictions for mercury.

As described for, the other metal-based components, water quality (Section 2.4), sediment quality (Section 4.4), and aquatic invertebrates tissue metals (Section 6.3), the evaluation of fish tissue metal monitoring results against NPMs were at near-field sites only:

- Davidson Creek: DC-05 and DC-15; and
- Creek 661: 661-05 and 661-10.

Turtle Creek (TC-05) was not included because the airstrip has not been constructed.

Fish tissue selenium and mercury concentration guidelines for the protection of aquatic life or wildlife are provided in Table 7.2-2. The specific NPMs used for baseline fish tissue metal concentrations including mercury and selenium are provided in Appendix E-10.

7.4.2 RESULTS

To meet the "none" NPM for fish tissue metal concentrations the mean annual fish tissue concentrations of selenium and mercury meet the following conditions:

- **[Condition 1]** lower than the tissue residue guideline for selenium or mercury in fish tissue; or
- **[Condition 2]** lower than or equal to the 95th percentile baseline concentration of fish tissue concentrations for selenium and mercury.

In 2025, mean selenium concentrations in rainbow trout collected at both impact and control stream sites were below the tissue guideline, thereby meeting Condition 1. Mean mercury concentrations in 2025 exceeded the mercury tissue guideline at both impact and control sites, including DC-05, DC-15, 661-05, 661-10, 705-05, and 705-10 (Section 7.3.2.3), and therefore did not meet Condition 1. However, mean 2025 selenium and mercury concentrations were below the site-specific NPM benchmarks at all stream sites (Appendix E-8 and Appendix E-10).

The "none" NPM was not met for mercury in fish tissues in 2025, the comparison to the "low" NPM for mercury in fish tissue concentrations was completed. To exceed the "low" NPM for water quality the mean annual fish tissue concentrations of mercury does not meet the following conditions:

- **[Condition 1]** lower than the tissue residue guideline for selenium or mercury in fish tissue; and
- **[Condition 2]** higher than the 95th percentile baseline concentration of fish tissue concentrations for selenium and mercury; and
- **[Condition 3]** changes in selenium or mercury in fish tissue concentrations are not statistically significant between near-field and control sites or compared to baseline conditions (BACI analysis).

Although Condition 1 was not met for mercury in fish tissues in 2025, Condition 2 and 3 were met. BACI analyses indicated no statistically significant differences in mercury concentrations between control and impact sites for rainbow trout in stream environments (Section 7.3.2.2). This indicates that although mercury concentrations exceeded the guideline, there was no systematic increase attributable to Mine-related activities, and changes in mercury concentrations were not significantly different between near-field and control sites or the before period. Therefore, the 2025 results indicate that no changes to existing mitigation measures are required, as mitigation practices continue to perform as expected.

7.5 SUMMARY AND RECOMMENDATIONS

Fish community composition in 2025 remained within the range of natural variability and did not show Mine-related effects. The 2025 fish tissue metal concentrations were similar to or lower when compared to baseline, with no Mine-related effects detected in streams or lakes. Aluminum,

mercury, and selenium were all below NPM benchmarks, and BACI analyses indicated no significant differences between control and impact sites. Mercury guideline exceedances occurred at both impact and control sites, consistent with baseline patterns, while selenium remained below guidelines for all fish and sites sampled.

No changes to fish community monitoring or tissue metal sampling or analyses the described in the AEMP Plan Version 4.0 is recommended, with the following exceptions:

- Investigate potential locations for alternative regional control sites to replace the existing control sites TC-01 and 661-01, as both sites have failed repeatedly to produce fish captures that meet minimum sample size requirements for analyses. Augmenting the number of regional control sites, with comparable channel morphology and fish community composition, will improve the reliability of future analyses and strengthen the defensibility of effects assessments. Only Fish Community Inventory sampling would be conducted at alternative regional control sites, no additional tissue sampling for the analysis of metal is recommended.
- Include large gee-style cylinder traps as an additional capture method at site TC-05 during tissue sampling for the analysis of metal to better target rainbow trout. The life stages observed at this site – primarily larger juveniles and adults – are less likely to enter standard minnow traps, which can introduce size-selectivity and reduce capture success. Using both the smaller minnow traps and the larger cylinder traps may increase the likelihood of capturing the full range of rainbow trout present and improve catch rates needed to meet sample size requirements.

8. KOKANEE SUMMER SPAWNING SURVEY

The purpose of the Kokanee Summer Spawning Survey is to monitor the size of the kokanee spawning run in the AEMP study area, and to describe population characteristics and spawning habitat. Kokanee spawning habitat was assessed for effects related to changes in water quality resulting from construction and operational activities.

8.1 MEASUREMENT AND ASSESSMENT ENDPOINTS

The assessment endpoints for the Kokanee Summer Spawning Survey include the number and density of spawning kokanee, the number and density of kokanee redds, fish length at maturity, substrate composition, and mesohabitat relative abundance (Table 8.1-1).

TABLE 8.1-1 MEASUREMENT AND ASSESSMENT ENDPOINTS FOR THE KOKANEE SUMMER SPAWNING SURVEYS

Measurement Endpoint	Assessment Endpoint
Kokanee spawning	• Number of spawning kokanee and density (kokanee/100 m^2) • Number of redds and redd density (redds/100 m^2) • Fish length at 100% maturity • Substrate composition (geometric mean diameter and percent composition of less than 0.85 mm diameter) • Mesohabitat relative abundance

8.2 SAMPLING SITES AND METHODS

Monitoring of spawning kokanee was completed at ten survey sections (Figure 8.2-1; Table 8.2-1), with two survey sections established within selected reaches, in each watercourse of interest, including:

- Reach 1 and 2 in Davidson Creek (DC-20)
- Reach 1 in Creek 661 (661-20)
- Reach 15 in Lower Chedakuz Creek (CC-15)
- Reach 20 in Middle Chedakuz Creek (CC-02)
- Reach 19 in Middle Chedakuz Creek (CC-05)

The selected reaches, identified during fisheries baseline studies (AMEC 2013a), within each of the watercourses provide data on the movement of spawning kokanee from Tatelkuz Lake and other waterbodies into specific watersheds, including the Davidson Creek watershed, the Creek 661 watershed, and Lower and Middle Chedakuz Creek watersheds downstream and upstream of Tatelkuz Lake.

In addition to the survey sections in Reach 1 of Creek 661 (661-20A-KO and 661-20B-KO), six additional survey sections (661-20C-KO through 661-20H-KO) were surveyed to determine the entire kokanee spawning distribution within the watercourse. The entire spawning distribution of kokanee in Davidson Creek was surveyed as part of the federal follow-up program for Decision Statement Condition 3.14.

A full description of the methods of the 2025 Kokanee Spawner Program, including measurement endpoints and sampling sites under the AEMP Plan (ERM 2025b), the FUP for Condition 3.14, and the FUP for Condition 3.16, is provided in the *2025 Kokanee Spawner Report* (Appendix E-2). Mid-July Kokanee spawner surveys were conducted between mid July and late September; specific survey dates by survey section are provided in Table 8.2-1. A description of the survey timing and termination with respect to the AEMP Implementation Framework is also described within the *2025 Kokanee Spawner Report*.

8.2.1 FIELD METHODS

Spawner surveys completed in 2022 included bank walk lengths of 500 m that were established to count Kokanee spawners and their redds. In 2023, site lengths were extended either 500 m further upstream or downstream, for a total length of 1,000 m to better capture spawning activity. The 2023 survey extents were maintained in 2025.

Kokanee and kokanee redds were counted weekly over the entire spawning run (i.e., approximately late July to mid September, although exact timing varied by watercourse) by a two-person crew hiking upstream along each survey section. Both live and dead kokanee were counted. Live fish were classified as migrating/holding, spawning, or spent, depending on their behaviour. Fish tallied as migrating/holding were swimming steadily, usually upstream, or holding in a group with no evidence of spawning activity. Spawning fish were those paired and engaged in courtship behaviour, with one or more mates, or actively digging or guarding a redd. Spent fish were those observed in pools and backwaters, or drifting downstream along the stream margins with clear damage to the body and fins.

A percentage value of observer efficiency (OE) was applied as a correction factor to raw kokanee counts for each section, for each survey, to account for individual that were present but not detected during the surveys. OE is the probability that a spawning kokanee was or could be seen by the observer and was estimated by field crews according to several factors that influence the ability of the observers to detect fish, such as water clarity, light conditions, precipitation, and stream morphology. Redds were recorded based on observations of cleaned gravel and local depressions in suitable spawning areas.

A subset of observed dead fish was assessed for sex, measured for fork length and postorbital-hypural length, and sampled for otolith collection (for ageing). Postorbital-hypural length was measure due to the variability of the morphological changes associated with the spawning condition (e.g., kype formation), and the likelihood of mouth or caudal fin damage and/or decomposition. Dead female kokanee were assessed as either spent (approximately 100% of eggs released), partially spawned (approximately 50% of eggs released), or not spawned (very few or no eggs released). A sample size of 30 dead fish per survey section were targeted for otolith collection to determine size and age at maturity.

Coordinates were collected at the start and end locations of each survey section with bankfull, and wetted width channel measurements taken every 200 m along fixed locations of each bank walk. In situ water quality measurements were recorded at the beginning and end of each bank walk.

Surface water measurements consisted of temperature (°C), dissolved oxygen (mg/L), pH, conductivity (µS/cm), and turbidity (NTU).

Bank walk surveys were continued until the end of the spawning season when spawning was deemed complete through repeated surveys with few to no kokanee observations in a given survey section. Additionally, bank walk surveys were terminated in sections where kokanee were deemed absent upstream of a migration barrier (i.e., beaver dam) through repeated surveys with no kokanee observations.

Spawning habitat availability and substrate assessments were conducted prior to the kokanee spawning period. Mesohabitat mapping, following the Fish Habitat Assessment Procedure (FHAP; Johnston and Slaney 1996) methodology was used to quantify the amount of riffle, run, and pool habitat along the entirety of each survey section. Substrate sampling was conducted to characterize and monitor changes to the substrate composition in kokanee spawning areas. Four riffle crests were randomly selected within each survey section for substrate sampling prior to the arrival of kokanee spawners. At each riffle crest, three samples were collected at 25%, 50%, and 75% of the channel width, totalling 12 substrate samples for each survey section. Samples were collected using a modified McNeil core sampler in accordance with the methods described in the *British Columbia Field Sampling Manual, Part D* (BC MWALP 2020). Substrate samples were shipped to ALS for laboratory particle size distribution analysis.

8.2.2 LABORATORY ANALYSIS

Age analysis on otoliths was conducted using the same methods and analyses as discussed in Section 7.2.2.1.

Particle size distribution analysis was completed by ALS and followed the Salmonid Spawning Gravel Composition Module in the Timer-Fish-Wildlife Ambient Monitoring Program Manual (Schuett-Hames et al. 1994; Schuett-Hames et al. 1999). Briefly, this involved three methods: dry sieving, wet sieving, and sedimentation using a pipette. The data from the three particle sizing methods were combined, and individual particle sizing (0.125 mm, 0.25 mm, 0.5 mm, 0.85 mm, 1.0 mm, 2.0 mm, 4.0 mm, 8.0 mm, 16.0 mm, 32.0 mm, and 64.0 mm) were reported by ALS.

8.2.3 QUALITY ASSURANCE/QUALITY CONTROL

The QA/QC for field equipment, electronic field forms, field notes, and data entry was carried out as discussed in Section 7.2.3.1.

8.2.4 DATA ANALYSIS

8.2.4.1 SPAWNER COUNT AND DENSITY

Density of kokanee spawners is used to standardize counts of kokanee among sampling years. Counts of kokanee observed during each survey were divided by the length and average wetted width (i.e., surface area) of the surveyed reach. Peak spawner density was defined as the highest single-day density observed throughout the spawning period and is presented as observed spawners by stream area (Number of Spawners/100 m^2).

In future, when there are sufficient data collected from multiple years and sites, a Mann-Kendall temporal trends analysis for kokanee spawners will be used to assess temporal changes in spawning activity for each kokanee run-year. It is hypothesized that if mine activities affected the kokanee community, then there would be a significant decrease in spawning activity at impact sites in comparison with spawning at control sites or there would be a significant decline in spawning activity over time.

8.2.4.2 REDD COUNT AND DENSITY

Density of kokanee redds is used to standardize counts of redds to allow for comparisons among sampling years. Counts of kokanee redds observed during each survey were divided by the length and average wetted with of the surveyed reach. Peak redd density was defined as the highest single-day density observed throughout the spawning period and is presented as observed redds by stream area (Number of redds/100 m^2).

In future, when there is sufficient data collected from multiple years and sites, a Mann-Kendall temporal trends analysis for kokanee redds will be used to assess temporal changes in spawning activity for each kokanee run-year.

8.2.4.3 ESCAPEMENT

Kokanee spawner escapement estimates are determined for Davidson Creek under the federal FUP for Condition 3.14. Kokanee spawner escapement estimates were also determined for Creek 661 using the same methodology.

Estimates of Kokanee escapement were calculated using the area-under-the-curve (AUC) method. This involved calculating the area under the plotted curve of abundance versus sampling date using integration. The area under this curve gives the estimated total number of fish-days. Two AUC methodologies were employed: Gaussian AUC (quasi-Poisson generalized linear model; GAUC) and Trapezoidal AUC (TAUC).

Escapement estimated used the live counts, adjusted for OE, obtained from the visual surveys. Adjusted live counts from all survey sections were pooled to provide a total count for use in the AUC calculations. Final escapement was estimated by dividing the AUC estimate by a value of survey life (synonymous with residence time). A full description of this data analysis is provided in the *2025 Kokanee Spawner Report* (Appendix E-2).

8.2.4.4 LENGTH AT MATURITY

Mean fork length and postorbital-hypural length, for each age, were calculated from carcass at aging data collected from Davidson Creek and in Middle Chedakuz Creek. There were insufficient aging sample sizes for statistical analysis from control sites in Middle Chedakuz Creek, as well as impact sites in lower Chedakuz Creek; therefore, comparisons of length-at-age among sites were not conducted.

8.2.4.5 SUBSTRATE COMPOSITION

Grain size composition (percent substrate less than 0.85 mm) and the geometric mean diameter were calculated from lab results provided by ALS (see Section 8.3.4). As this was the first year of

conducting substrate composition via the McNeil Core sampling method in Middle Chedakuz Creek and Creek 661, temporal comparisons were not conducted.

8.2.4.6 MESOHABITAT

Mesohabitat data were used to evaluate the relative abundance (%) of riffle, run, glide, and pool habitat types in each survey section. Relative abundance was calculated as the total length of each habitat type divided by the total length of the survey section. Pairwise comparisons of mesohabitat relative abundance among years, via a Kruskal-Wallis test, were completed for each survey section with two or more years of available data.

8.2.5 EXCEPTIONS TO METHODS

Table 8.2-2 provides a summary of the exceptions from the proposed sampling methods indicated in the AEMP Plan (ERM 2025b).

TABLE 8.2-2 SUMMARY OF EXCEPTIONS TO METHODS, 2025 KOKANEE SPAWNER SURVEYS

Methods Indicated in AEMP Plan Version 4.0	Methods Completed in 2025
At each riffle crest, three samples will be collected at 25%, 50%, and 75% of the channel width, totaling 12 substrate samples for each survey reach.	Large cobble boulder substrates encountered at a number of substrate sampling transects (riffle crests) in Creek 661 (survey section 661-20A-KO) and Middle Chedakuz Creek (survey sections CC-02A-KO and CC-02B-KO) prevented successful collection of 12 samples per survey reach.

8.3 RESULTS AND DISCUSSION

Results of the 2025 Kokanee Spawner Program, including measurement endpoints and sites sampled under the AEMP Plan (ERM 2025b), the FUP for Condition 3.14, and the FUP for Condition 3.16, are provided in the *2025 Kokanee Spawner Report* (Appendix E-2). The site and survey information, field water quality data, bank walk effort and observer efficiencies recorded during each survey, individual fish data, and fish aging results are provided within the appendices of that report.

The kokanee salmon life cycle (fertilization to spawning and death) can span from three to five years, with the majority of fish returning to spawn and then die in their fourth year. Similar to sockeye salmon and other Pacific salmon species, fish returning each year are the progeny of fish that spawned four years earlier and mostly separated from other years. Because of this cyclical trend, each cohort should be treated as a separate entity in assessing abundance trends, rather than a general assessment of abundance across all years.

There are baseline data for kokanee spawning for three of four possible cohorts (Table 8.3-1). These data are based on the kokanee spawning surveys that occurred in 2011, 2012, 2013 (AMEC 2013a, 2013b), 2022 (ERM 2023), and 2023 (ERM 2024), assuming a four-year run cycle.

TABLE 8.3-1 EXAMPLE OF FOUR-YEAR RUN CYCLE AND AVAILABLE DATA

Cohort 1	Cohort 2	Cohort 3	Cohort 4
2011	**2012**	**2013**	2014
2015	2016	2017	2018
2019	2020	2021	**2022**
2023	*2024*	*2025*	2026

Notes:
Bolded dates indicate years of available baseline data; italicized date indicates year of available data collected during construction and operational phases.

8.3.1 KOKANEE SPAWNER AND REDD DENSITY

Kokanee and redd densities by individual survey section are provided in Figures 8.3-1 and 8.3-2, respectively. These figures include 2023 and 2024 following the adjustment of survey lengths to approximately 1,000 m and the addition of control survey sections in CC-02 in 2023. It also includes adjustment of the Davidson Creek survey sections to DC-1A-KO and DC-2-KO following changes made in AEMP Plan, Version 4.0 (ERM 2025b). In previous years, survey sections DC-1A-KO and DC-3-KO were surveyed under the AEMP; however, a large beaver dam, located in the lower portion of DC-3-KO has limited kokanee spawning use throughout most of this section since 2023. As such, DC-3-KO was replaced by DC-2-KO (reach 2). The timing of kokanee spawning appears similar among years; however, the peak kokanee and redd densities, observed in each survey section, were variable.

Peak kokanee density, observed in 2025 in the DC-20 reach, was generally similar to 2024 (Table 8.3-2). Peak densities observed in 2025 in the CC-02, CC-05, and 661-20 reaches were higher than in 2024. Peak spawning was likely missed in these watercourses in 2024 due to the wildfire and delayed start of the field surveys in Middle Chedakuz Creek and Creek 661. In contrast, the entire spawning season was observed in 2025.

Peak redd densities observed in 2025 were generally lower than in 2024 in all reaches. Limited Kokanee spawning was observed in the Lower Chedakuz Creek survey sections (CC-15A-KO and CC-15B-KO) in 2025. As weekly bank walks were conducted throughout the expected spawning window—and water clarity and visibility during these surveys did not greatly hamper the crew's ability to detect fish—it is unlikely that the run was simply missed. These reduced observations may reflect factors such as lower adult returns or unfavourable flow or temperature conditions during the spawning period.

There are currently insufficient years of kokanee spawner and redd count data, for both control and impact reaches, to conduct trend analysis in peak kokanee or redd densities.

8.3.2 ESCAPEMENT ESTIMATES—DAVIDSON CREEK AND CREEK 661

Kokanee spawner escapement estimates are determined for Davidson Creek under the federal FUP for Condition 3.14 and are provided below with the escapement estimates for Creek 661. Both AUC models provided similar estimates of escapement (Table 8.3-3) for Creek 661 in 2025, while the Davidson Creek GAUC model estimate was approximately 1200 (19%) greater than the TAUC model estimate.

TABLE 8.3-3 KOKANEE ESCAPEMENT ESTIMATES FOR DAVIDSON CREEK AND CREEK 661, 2024 AND 2025

Watercourse	Year	Model	Estimate	Standard Error	Lower 95%	Upper 95%
Davidson Creek	2025	GAUC	7,372	2,216	3,030	11,715
	2025	TAUC	6,193	2,161	1,958	10,429
	2024	GAUC	9,058	1,389	6,336	11,644
	2024	TAUC	8,923	1,388	6,201	11,644
Creek 661	2025	GAUC	1,806	167	1,479	2,134
	2025	TAUC	1,763	119	1,529	1,996

8.3.3 LENGTH AT MATURITY

Mean fork length and postorbital-hypural length, by age class, are provided in Table 8.3-4. Generally, kokanee had similar lengths at age in Davidson Creek and Middle Chedakuz Creek. Comparisons among control and impact sites were not completed due to insufficient ageing data collected in the control sections of Middle Chedakuz Creek.

TABLE 8.3-4 MEAN FORK LENGTH AND POST-ORBITAL HYPURAL LENGTH, BY AGE CLASS, 2025

Watercourse	Age	Fork Length (mm)		Postorbital-Hypural Length (mm)	
		n	Mean ± SD	n	Mean ± SD
Middle Chedakuz Creek (Control - CC-02)	4	1	239	1	199
Middle Chedakuz Creek (Impact – CC-05)	3	14	223.1 ± 12.2	14	173.2 ± 45.4
	4	12	231.9 ± 10.3	12	189.4 ± 14.6
Lower Chedakuz Creek (impact)	4	1	241	1	197
Davidson Creek (impact)	3	24	229.6 ± 11.5	24	185.1 ± 37.2
	4	24	233.6 ± 11.4	24	195.2 ± 10.1

8.3.4 SUBSTRATE COMPOSITION

In 2025, sampling for substrate composition was completed in Creek 661 and Middle Chedakuz Creek only. Due to a wildfire-reduced field season in 2024, sampling in these watercourses was not completed and thus they were sampled in 2025. No other watercourses were sampled in 2025 given the once-per-three-year sampling frequency. Substrate composition particle size results for 2025 are provided in Table 8.3-5. Substrate composition particle sizes for the watercourses sampled in 2024 are also presented in Table 8.3-5. During preparation of this report, an error was identified in the calculation of the geometric mean diameters provided in the 2024 AEMP interpretive report; the affected values were reviewed and recalculated, and replace those previously reported. These corrections ensure consistency and accuracy in the long-term dataset that will be used in the future to assess mine-related effects on spawning habitat. Comparison to baseline conditions was not possible as this was the first-year substrate sampling, using a McNeil Core Sampler, was conducted in Creek 661 and Middle Chedakuz Creek.

TABLE 8.3-5 SUBSTRATE COMPOSITION PARTICLE SIZES, 2024 AND 2025

Year	Site	Site Type	n	Percent Less than 0.85 mm (%)				Geometric Mean Diameter (mm)

8.3.5 MESOHABITAT

Mesohabitat assessments were first completed in all AEMP sites in 2023, except for 661-20B-KO. In 2024, mesohabitat assessments were only completed for Davidson Creek and Lower Chedakuz Creek due to a wildfire-reduced field season. In 2025, mesohabitat assessments were successfully completed in all AEMP sites (Table 8.3-6). Several factors limit the reliability of comparing results across years. Observer bias may explain some of the observed differences, particularly between 2023 and the subsequent two years, when a different consulting company took over the assessments. Although efforts were made in 2024 and 2025 to maintain consistency in field personnel, variation in how crews interpret and classify habitat types can still influence outcomes. Environmental conditions, including turbidity, sun glare, weather, and flow, can also affect how habitat boundaries are perceived by altering visibility, obscuring substrate or depth transitions, and changing the apparent shape or extent of habitat units. High or low flows, in particular, can temporarily expand, compress, or mask certain habitat types, leading to differences in classification that reflect survey conditions rather than true habitat change. Survey timing further complicates comparisons: assessments in 2023 were conducted in late August and late September, whereas the 2024 and 2025 surveys occurred in mid-July. Although discharge was measured in 2024 and 2025, it was not collected in 2023, preventing consistent use of flow data to help contextualize results across all three years. Together, these methodological and environmental inconsistencies reduce confidence in direct year-to-year comparison.

8.4 SUMMARY AND RECOMMENDATIONS

Kokanee presence and spawning activity in 2025 at all monitored sites indicate continued support of natural kokanee life-history patterns. Differences in peak spawner and redd densities appear to reflect natural variability, annual hydrology, and survey-timing effects. The limited number of years of available data for individual Kokanee cohorts prevents assessment of potential Mine-related effects at this time.

No additional sampling or analyses other than that described in the AEMP Plan (ERM 2025b) is recommended, with the following exceptions:

- Incorporation of an additional impact survey section (CC-05A2-KO) in Middle Chedakuz Creek. In August 2025, a one-time survey during peak spawning was conducted over the entire length of Middle Chedakuz Creek to fill knowledge gaps with respect to kokanee spawning habitat use and condition; results of that survey were reported under separate cover. Based on the recommendations within that report, the addition of CC-05A2-KO will help to improve statistical robustness and spatial representativeness of the kokanee spawner program.
- Alternative approaches to monitoring kokanee spawning habitat should be explored. In particular, incorporating detailed habitat surveys that quantify the extent and condition of high-use spawning areas would provide more reliable information for detecting habitat change. The current FHAP methodology, used to determine relative abundance of mesohabitat, is strongly influenced by observer interpretation and short-term environmental variability (e.g., flow, turbidity) resulting in low repeatability and inconsistent data across years. These limitations reduce the method's ability to detect subtle or cumulative habitat changes associated with Mine effects, making it poorly suited for robust effects assessments.

9. KOKANEE FRY SPRING OUTMIGRATION SURVEY

The purpose of the Kokanee Fry Spring Outmigration Survey is to monitor the success of the kokanee spawning run in the AEMP study area. The results of the surveys were assessed for effects related to changes in water quality as a result of construction and operational activities.

9.1 MEASUREMENT AND ASSESSMENT ENDPOINTS

The assessment endpoints for the Kokanee Fry Spring Outmigration Survey consisted of total fry abundance for the outmigration period, and the condition of fry (Table 9.1-1).

TABLE 9.1-1 MEASUREMENT AND ASSESSMENT ENDPOINTS FOR THE KOKANEE FRY OUTMIGRATION SURVEY

Measurement Endpoint	Assessment Endpoint
Kokanee fry outmigration	Calculated total fry abundance for the outmigration period
Kokanee fry health	Condition—length and weight

9.2 SAMPLING SITES AND METHODS

Five sites were monitored for kokanee outmigration (Table 9.2-1; Figure 9.2-1) including:

- One site in Davidson Creek (DC-20)
- One site in Creek 661 (661-20)
- One site in Lower Chedakuz Creek (CC-15)
- Two sites in Middle Chedakuz Creek (CC-05 and CC-02)

Sampling at these sites provided data on the movement of kokanee fry from specific watersheds, including the Davidson Creek watershed, the Creek 661 watershed, and Lower and Middle Chedakuz Creek watershed. The control site (CC-02) in Middle Chedakuz Creek is located immediately upstream of the confluence with Creek 661. The CC-05 sampling location at the mouth of Middle Chedakuz Creek, at Tatelkuz Lake, captures out-migrating fry from the entirety of the Middle Chedakuz watershed; this site intercepts fry that are also sampled at CC-02 and 661-20. The CC-15 sampling location in Lower Chedakuz Creek captures out-migrating fry from the portion of the watercourse between the Tatelkuz Lake outlet and the sampling location but may also intercept fry outmigration from Davidson Creek (sampled at DC-20).

A full description of the methods of the 2025 Kokanee Fry Spring Outmigration surveys, including measurement endpoints and sampling sites under both the AEMP Plan (ERM 2025b) and the FUP for Condition 3.14, is provided in the *2025 Kokanee Fry Outmigration Report* (Appendix E-3). Surveys took place from mid April to late June 2025 (Table 9.2-1). This period covered the spring freshet, which is when the kokanee fry are expected to return to the lake (AMEC 2013a, 2013b). A description of the survey timing and termination with respect to the AEMP Implementation Framework is also described within the 2025 Kokanee Fry Spring Outmigration Report.

Notes: Coordinates are in North American Datum (NAD) 83, Universal Transverse Mercator (UTM) Zone 10.

9.2.1 FIELD METHODS

Two fine-mesh funnel nets (based on Fraley and Clancey [1988]) with associated box traps were deployed at each site regularly throughout the outmigration period (Table 9.2-1). During the pre- and post-peak outmigration periods, sampling occurred once every five nights. Sampling increased to every second night during the main migration period. Sampling occurred overnight, typically between the hours of 20:00 and 03:30, as most (greater than 90%) fry outmigration typically occurs between 19:00 hours and 02:00 hours (Manson 2005). During each sample night, nets were set and checked at approximately 30-minute intervals, with fish collection and processing occurring after each funnel net set.

Captured fish were identified to species and enumerated. During each sample night, a subset of 30 fry were measured for length (to the nearest 1 mm) and weight (to the nearest 0.01 g). Any deformities, erosion, lesions, and/or tumours (DELTs), parasites, or other anomalies were noted.

Stream measurements, consisting of mean wetted width, bankfull width, water depth, and discharge, were recorded during each site visit. The wetted cross-sectional area of the net openings and the wetted cross-sectional area of the stream at the net location was also collected during each night.

Trap efficiency was determined via a mark-recapture program, conducted over two-night sampling events. Mark-recapture events occurred once every five nights at each site, when capture rates allowed. Captured fry were marked with Bismarck Brown Y solution on night one, held instream in a live car until the following morning then released upstream (approximately 500 m) of the capture location. On night two, recaptured marked fish were counted and used to calculate trap efficiency. A subset of marked and unmarked fry (a maximum of 20 each) were temporarily held in mesh bags in the live car to assess marking survival rate.

9.2.2 LABORATORY ANALYSIS

No laboratory analyses were required for the Kokanee Fry Spring Outmigration Surveys.

9.2.3 DATA ANALYSIS

9.2.3.1 KOKANEE FRY ABUNDANCE

Kokanee fry total abundance was calculated as the sum of all nightly out-migrating fry estimations. Two sets of nightly estimates were calculated:

1. Trapping Efficiency Catch Expansion, using trap efficiency, estimated by the sub-sampling mark-recapture approach; and
2. Area-based Catch Expansion, comparing the wetted cross-sectional area of the stream at the sampling location to the wetted cross-sectional area of the net opening.

Trap efficiency measures how well a trap captures fish that pass through the site (i.e., the proportion of fish that migrate past the site that are actually caught). It is estimated by the ratio of recaptured, marked fish to the total number of marked fish. This ratio is then corrected for small sample bias by applying a Chapman correction (Chapman 1951; Ricker 1975). Abundance estimates at each sampling visit was estimated by dividing the catch at each sampling visit by the site-specific Chapman-corrected trap efficiency, thereby expanding the sample to account for fish that passed the site but were not captured.

The area-based estimate expands the catch based on the ratio of the wetted cross-sectional area of the net opening to the wetted cross-sectional area of the stream at the sampling location. The estimate per set is then further expanded for the period that was not fished. The total nightly catch was then calculated as the sum of all time interval fry abundance estimates.

Estimates of Kokanee fry outmigration abundance were calculated using a trapezoidal area-under-the-curve (TAUC) method. By using the two nightly catch expansion methods, two estimates of kokanee total fry outmigration abundances were calculated for each site.

During a review of previous years' datasets, some data anomalies were noted for a number of sampling events at CC-02, CC-05, and 661-20 in 2024; therefore, the erroneous data were removed, and abundance estimates for 2024 were recalculated. Attempts were also made to recalculate escapement estimates for 2023 to generate the standard errors and confidence limits missing from the original analyses. However, there were insufficient available raw data (e.g., missing wetted areas of the sampling sites and nets) that prevented recalculation.

9.2.3.2 KOKANEE FRY CONDITION

Fish condition was assessed using the same methods as described in Section 7.2.4.4. Data collected from 2024 were excluded as fish weights were recorded to the closest 0.1 g, rather than 0.01 g.

9.2.3.3 EGG-TO-FRY SURVIVAL

Egg-to-fry survival estimates were calculated for the surveyed watercourses where data were available. Egg-to-fry survival is expressed as a percentage of estimated escapement to estimated potential egg deposition. As two estimates of escapement were calculated for 2025, using an area-based method and mark-recapture method, each were used to provide estimates of egg to fry survival.

The potential egg deposition (PED_t) provides an estimate of the total number of eggs that could be deposited during the spawning year (2024), and it was calculated as follows (Plate et al. 2018):

$$PED_t = N_f \times PED_f$$

where:

- PED_t = Potential total eggs deposited;
- N_f = Number of females; and
- PED_f = Potential eggs deposited per female.

The number of females in the spawning population (N_f) was derived as follows:

$$N_f = \frac{F_s}{T_s} \times P_a$$

where:

- F_s = number of females sampled;
- T_s = total number of fish sampled; and
- P_a = Population abundance (total abundance estimate)

The F_s / T_s term is simply the proportion of females in the population. It was derived using observed sex ratios from the 2024 spawning year (ERM 2025a). If sex ratio data were unavailable, the proportion of females was assumed to be 50%.

The potential eggs deposited per female (PED_f) was calculated as follows:

$$PED_f = f - r$$

where:

- f= mean fecundity and
- r = mean egg retention.

As egg retention and fecundity require extensive invasive sampling resulting in excessive mortalities, and are outside the scope of this program, mean egg retention and fecundity values were estimated. The mean egg retention value was adapted from Bassett and Baxter (2023). Studies of adult Kokanee populations have shown a positive relationship between fecundity and fork length, indicating that reproductive potential increases with female body size (Elgar 1990,

McGurk 2000, Wilson and Shrimpton 2021). To account for this relationship, estimated fecundity was calculated as follows (Sebastian et al. 2003):

$$Log_{10} f = 2.2955(Log_{10}\, FL) - 3.0068$$

where:

- *f* = mean fecundity (number of eggs per female); and
- *FL* = mean fork length in mm from the 2024 spawning year.

As two estimates of fry outmigration abundance were calculated for 2025, using an area-based method and mark-recapture method, each were used to provide estimates of egg-to-fry survival. Egg-to-fry survival estimates for 2024 were also recalculated using the above methodology to ensure consistency and accuracy in the long-term dataset.

9.2.4 EXCEPTIONS TO METHODS

Table 9.2-2 provides a summary of the exceptions from the proposed sampling methods indicated in the AEMP Plan (2025b).

TABLE 9.2-2 SUMMARY OF EXCEPTIONS TO METHODS, 2025 KOKANEE FRY OUTMIGRATION SURVEYS

Methods Indicated in AEMP Plan Version 4.0	Methods Completed in 2025
Egg-to-fry survival calculations will include literature cited fecundity values will be used to remove the need for intrusive lethal sampling of females.	Egg-to-fry survival calculations modified to include estimated fecundity, based on methodology in Sebastian et al. (2003) which uses a fork length variable to determine fecundity, rather than literature cited values.

9.3 RESULTS AND DISCUSSION

Results of the 2025 Kokanee Fry Spring Outmigration Program, including measurement endpoints and sampling under both the AEMP Plan (ERM 2025b) and the FUP for Condition 3.14, are provided in the *2025 Kokanee Fry Outmigration Repor*t (Appendix E-3). The site and survey information, field water quality data and fish sampling effort recorded at each site, individual fish data (including Fulton's conditions), and mark-recapture data are provided within the appendices of that report.

Cumulatively 1,048.06 hours of sampling effort across all sites resulted in the capture of 62,303 fish, including incidental species (lake chub, largescale suckers, longnose dace, longnose sucker, mountain whitefish, northern pikeminnow, rainbow trout, and prickly sculpin). Nightly catches ranged from 10 to 3,467 fish. Overall, 59,943 Kokanee fry were captured across all sites.

A total of 729 kokanee fry mortalities were recorded during funnel net sampling and Bismarck Brown Y Dye marking events, equating to an overall mortality rate of 1.22%. Funnel net sampling accounted for 396 mortalities, while marking events and mortalities studies accounted for 333 mortalities. The number of fry mortalities, and mortalities of other fish species, detailed by site and observed cause, are provided in 2025 Kokanee Fry Outmigration Report.

9.3.1 ABUNDANCE

Due to the cyclical trend of kokanee spawning, each spawning cohort and resulting fry outmigration should be treated as an independent population in assessing abundance trends, rather than a general assessment of abundance across all years. Kokanee Fry Spring Outmigration surveys have only been completed in 2023, 2024, and 2025. Kokanee fry were not captured at the original control site (CC-01) in 2023; thus, 2024 is the only year for which there are baseline data from a control site (CC-02).

Abundance results for 2023, 2024, and 2025 are summarized (Table 9.3-1). In all instances, the trap-efficiency (mark-recapture) based estimates are substantially greater than the area-based estimates. Abundance estimates were greater at all sites in 2025 and may be attributable to the increased sampling frequency relative to previous years (Table 9.3-2). More frequent sampling provides a finer temporal resolution of short-term migration dynamics, allowing for improved detection of variability in fry movement patterns. In particular, the increased sampling frequency enables clearer identification of outmigration peaks and troughs that may have been underrepresented or missed in previous monitoring efforts with lower sampling intensity. By capturing these fluctuations more effectively, the resulting estimates are expected to provide a closer approximation of actual kokanee fry abundance. Recognizing the limitations created by past variability, future monitoring will follow the methodology used in 2025 and the AEMP Implementation Framework to support reliable year-to-year comparisons.

TABLE 9.3-1 KOKANEE FRY OUTMIGRATION ABUNDANCE ESTIMATES, 2023 TO 2025

Site	Year	Area-Based Abundance			Mark-Recapture Abundance		
		Estimate	LCL	UCL	Estimate	LCL	UCL

9.3.2 CONDITION

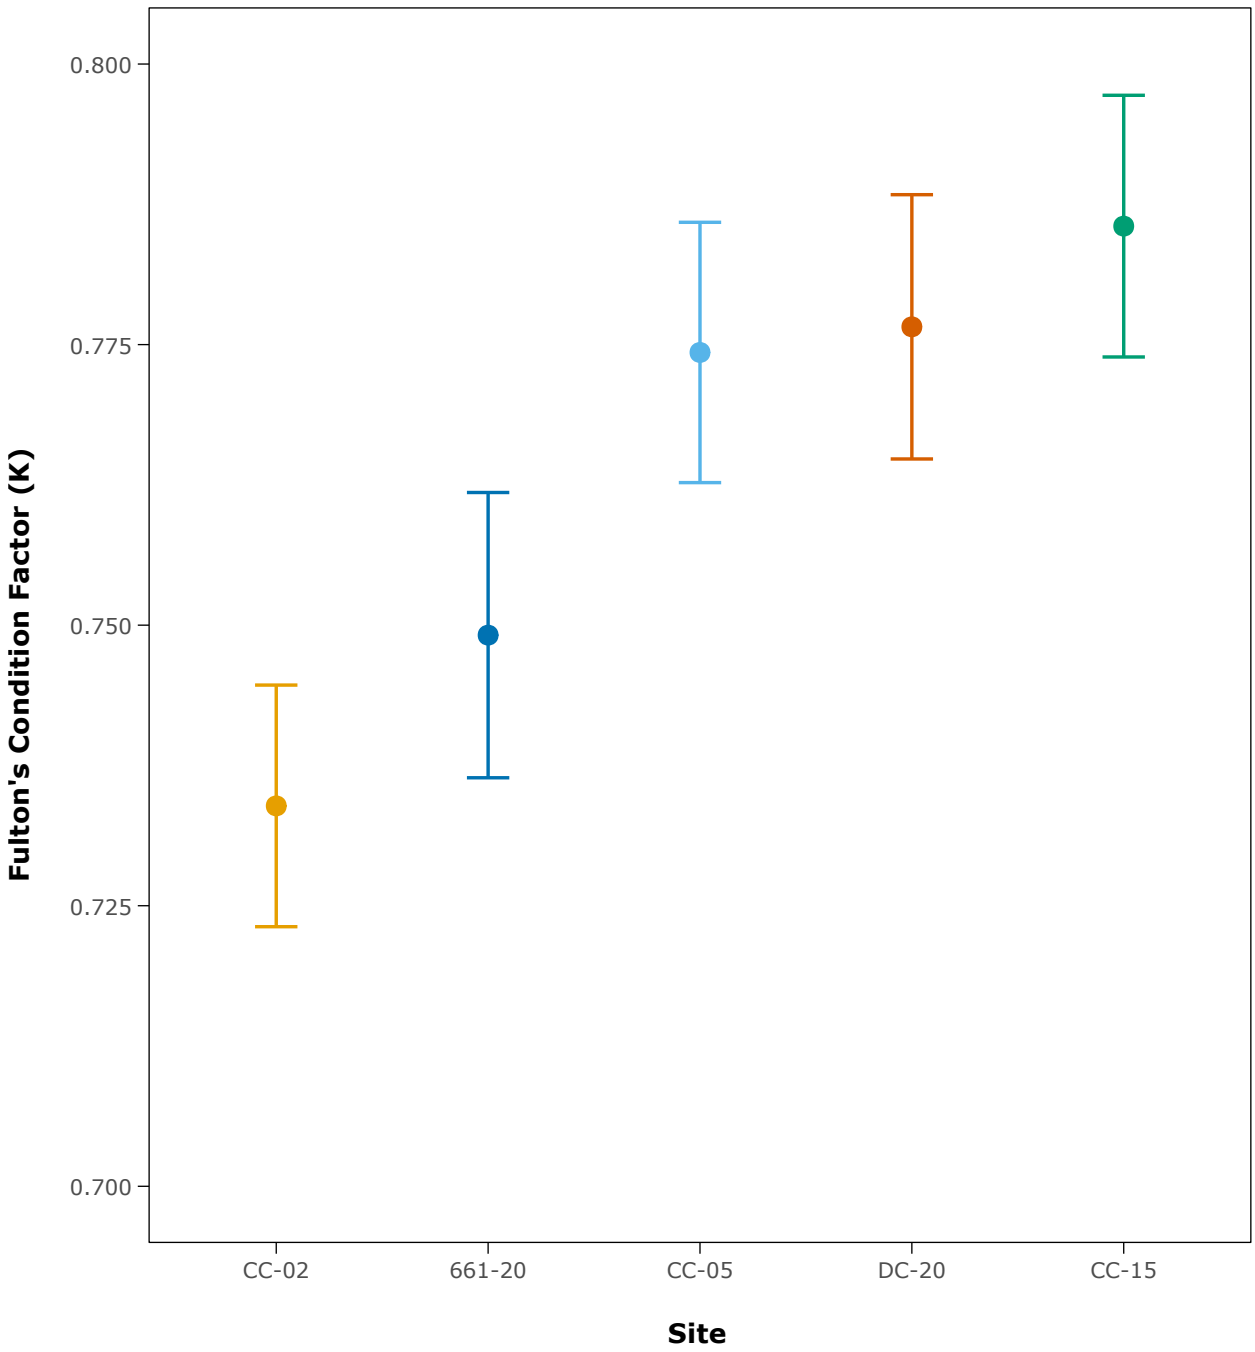
Fulton's condition factor of kokanee fry at each site sampled in 2025 is shown in Figure 9.3-1. The condition of kokanee fry was significantly greater in impact sites DC-20, CC-05 and CC-15 when compared to control site CC-02, but the magnitude of the difference was small (Table 9.3-3; Appendix E-5). Fulton's condition was not significantly different between impact site 661-20 and control site CC-02. Although statistical differences were observed among sites, they were well within the with natural variability observed at all sites.

TABLE 9.3-3 2025 FULTON'S CONDITION OF KOKANEE FRY AND STATISTICAL COMPARISONS

Site	Site Classification	n	Mean ± SD	Impact vs Control	
				p	%[a]
CC-02	Control	983	0.73 ± 0.17	-	-
661-20	Impact	827	0.75 ± 0.19	0.870	2.7
CC-05	Impact	884	0.77 ± 0.18	<0.001	5.3
DC-20	Impact	1,087	0.78 ± 0.20	<0.001	6.6
CC-15	Impact	985	0.79 ± 0.19	<0.001	7.9

Notes: < = less than; n= sample count; SD = standard deviation
[a] The percent difference between impact and control mean.

FIGURE 9.3-1 MEAN FULTON'S CONDITION FACTOR OF KOKANEE FRY, 2025



Notes: Error bars represent the 95% confidence intervals.

Comparisons of impact sites to the control site could not be conducted for previous years. In 2023, fry were not captured at the control site, and fish weights in 2024 were recorded to the nearest 0.1 g rather than 0.01 g.

9.3.3 EGG-TO-FRY SURVIVAL

Egg-to-fry survival estimates for 2025 were calculated for Davidson Creek only (Table 9.3-4), as this was the sole watercourse for which estimates of overall 2024 Kokanee spawner escapement and 2025 Kokanee fry outmigration abundance were available. It should be noted that egg to fry survival estimates may not be reliable due to a small sample size for sex ratio information and the absence of fecundity and egg retention values specific to the sampled watercourses.

TABLE 9.3-4 KOKANEE EGG-TO-FRY SURVIVAL, 2024 AND 2025

Site	Year	Egg-to-Fry Survival (%)	
		Area-Based Outmigration Estimate	Mark-Recapture Outmigration Estimate
DC-20	2024	2.59	5.72
	2025	15.09	23.80

Egg-to-fry survival estimates were not calculated for Creek 661 due to the absence of kokanee spawner abundance estimates in 2024; this was due to the wildfire-reduced survey season. In future, barring any external factors such as wildfires or other extenuating circumstances, annual estimates of both kokanee spawner escapement and fry outmigration should be available for both Davidson Creek and Creek 661. These data will then allow for the calculation of egg-to-fry survival at each watercourse.

9.4 SUMMARY AND RECOMMENDATIONS

Limited years of data for kokanee fry metrics (abundance, condition, egg to fry survival) prevented assessment of potential Mine-related effects. Increased sampling frequency improved the reliability of the fry abundance estimates in 2025.

No additional sampling or analyses other than that described in the AEMP Plan (ERM 2025b) is recommended, with the following exceptions:

- Adjust the AEMP Implementation Framework commencement trigger by reducing the ATU threshold. Monitoring in 2025 indicates that Kokanee fry outmigration in Davidson Creek and Middle Chedakuz Creek occurs at a lower ATU value than the current trigger reflects. Lowering this threshold will support more accurate, watercourse-specific timing for sampling events.
- Update the egg-to-fry survival calculation to the method outlined in this report. Because this approach incorporates fish length as a variable, it likely provides a more accurate and representative estimate of egg production than relying solely on literature cited values.

10. RAINBOW TROUT SPRING SPAWNING SURVEY

The purpose of the Rainbow Trout Spring Spawning Survey is to monitor the size of the rainbow trout spawning run in the AEMP study area. The results of the surveys were used to assess effects related to changes in water quality or from the rerouting of water from Lake 1682 into Lake 1538 on rainbow trout spawning success.

10.1 MEASUREMENT AND ASSESSMENT ENDPOINTS

Measurement and assessment endpoints were specifically selected with a focus on non-lethal monitoring of the fish community. The spring spawning survey measurement endpoints included an inventory of the number of spawning rainbow trout, as well as the age, length, and weight of the spawning rainbow trout (Table 10.1-1).

TABLE 10.1-1 MEASUREMENT AND ASSESSMENT ENDPOINTS FOR THE RAINBOW TROUT SPRING SPAWNING SURVEY

Measurement Endpoint	Assessment Endpoint
Fish inventory	• Abundance of spawning rainbow trout • Population structure—length and age
Fish health	• Condition—length and weight

10.2 SAMPLING SITES AND METHODS

Rainbow trout spawning was monitored at three sampling locations (Figure 10.2-1; Table 10.2-1) from late April to late June 2025. Sample locations were selected based on baseline studies (AMEC 2013a). The site selection was designed to provide data on the movement of spawning rainbow trout from Tatelkuz Lake and Kuyakuz Lake into specific watersheds, including the Turtle Creek watershed, Davidson Creek watershed, and the Creek 661 watershed.

- Surveys were completed within the lowest reach of each watercourse of interest, as follows:
- Reach 1 in Turtle Creek (TC-15),
- Reach 1 in Davidson Creek (DC-20), and
- Reach 1 in Creek 661 (661-20).

TABLE 10.2-1 RAINBOW TROUT SPAWNER SURVEY SITES AND SAMPLING DATES, 2025

Site	Site Type	UTM Coordinates		Dates Sampled
		Easting (m)	Northing (m)	
TC-15	Control	383285	5908710	May 1 to June 12
DC-20	Impact	384290	5907870	April 23 to June 16
661-20	Impact	388630	5899450	April 25 to June 19

Notes:
Coordinates are in North American Datum (NAD) 83, Universal Transverse Mercator (UTM) Zone 10.

A full description of the methods of the 2025 Rainbow Trout Spring Spawner program, including measurement endpoints and sampling sites under both the AEMP Plan (ERM 2025b) and the FUP for Condition 3.14, is provided in the *2025 Rainbow Trout Spawner Report* (Appendix E-4). A description of the survey timing and termination with respect to the AEMP Implementation Framework is also described within the 2025 Rainbow Trout Spawner Report.

10.2.1 FIELD METHODS

An upstream-facing (for downstream migrating fish) box trap and a downstream-facing (for upstream migrating fish) box trap were installed at each site prior to the start of the predicted rainbow trout spawning movement. In 2025, the upstream and downstream box traps, and associated rigid channel-spanning fish fences, were separated from each other by approximately 10 m at DC-20 and 661-20 to reduce water pressure on the fences, to reduce turbulence, to minimize risk of fish impingement, and to improve flow refugia within the boxes. Based on observations made in 2024 with regards to fish mortality, the hardware cloth walls of box traps and several fence panels were replaced with half-inch mesh to mitigate the risk of injury or mortality to juvenile and small-bodied fish.

Box traps were checked daily for spawning rainbow trout. Captured fish were identified, enumerated, and measured for length (to the nearest 1 mm) and weight. Adult fish were weighed to the nearest gram while smaller fish were weighed to the nearest 0.1 g. Rainbow trout exhibiting signs of sexual maturity, i.e., expressing gametes or changes to colour/body characteristics, were tagged with a passive integrated transponder (PIT). Aging structures (scales) were collected from a subset of 30 rainbow trout per size class, per site, for fish greater than 200 mm fork length (i.e., 3+ age classes that are migrating to spawn). Any DELTs, parasites, or other anomalies on fish were noted.

Following processing, all fish were released above or below the fence from which they were captured (i.e., in the same direction in which they were migrating). When incidental mortalities occurred, otoliths were collected, and fish were dissected to confirm sex and spawning status.

10.2.2 LABORATORY ANALYSIS

Collected scales and/or otoliths were assessed using the same methods and analyses as discussed in Section 7.2.2.1.

10.2.3 QUALITY ASSURANCE/QUALITY CONTROL

The QA/QC methods for field equipment, electronic field forms, field notes, and data entry were carried out as discussed in Section 7.2.3.1.

10.2.4 DATA ANALYSIS

10.2.4.1 ABUNDANCE

Total adult spawner abundance was determined at each box trap site based on the number of PIT tags encountered, either applied in 2025 or existing from previous years. Current years recaptures were excluded from the total abundance tally. Sampling under the FUP for Condition 3.14 also

captured rainbow trout spawners at a box trap site located upstream, near the mine site. PIT tags encountered at that site, but not encountered at the DC-20 site, were included in the abundance total.

Multiple scenarios may have impacted the estimates of spawner abundance, including when fish:

- potentially migrated upstream before the traps were installed;
- potentially bypassed the traps due to loss of trap or fence integrity or isolation; or
- escaped during transfer from trap to holding buckets prior to PIT tagging.

To account for these scenarios, PIT tags were also implanted in untagged fish captured in the downstream migration trap boxes and were added to the total abundance tally.

To account for a gap in PIT tagging that occurred at the end of the sampling season between June 16 and 19, 2025, when the on-site supply of PIT tags was exhausted, as well as spawners that were not tagged due to poor body condition, non-tagged adults were included in the abundance tally. Untagged fish captured migrating downstream during, or after, these dates were included in the abundance tally only if it was confirmed that a fish of similar length was not previously captured migrating upstream. Mortalities encountered in the box traps or on the fences were also included if they were untagged but had evidently spawned during the sampling period.

10.2.4.2 POPULATION STRUCTURE

Population structures of fish were assessed using length frequency distributions and length-age regressions. Juvenile rainbow trout encountered during spawner surveys were excluded from the analyses because only adult fish (i.e. spawners) represented the life stage relevant to the assessment endpoints. The length frequency-distributions between control and impact sites were compared using a two-level Kolmogorov-Smirnov test. A minimum of eight individual length measurements was considered the minimum sample size required for the Kolmogorov-Smirnov test. Kolmogorov-Smirnov tests were also used to compare length frequency distributions among years. Data collected prior to 2022 were omitted as life stage was not reliably documented in those years.

Differences in fish growth of adult rainbow trout returning to the control site and the impact sies were evaluated using a nested analysis of covariance (ANCOVA). Site-specific growth rate was determined using the slope of the length-age relationships. Data were log-transformed (natural log) prior to analysis to help meet the assumptions of an ANCOVA, and to linearize the relationship between age and length.

10.2.4.3 CONDITION

Fish condition was assessed using the same methods as described Section 7.2.4.4. Juvenile rainbow trout encountered during spawner surveys were excluded from the condition analysis because only adult fish (i.e., spawners) represented the life stage relevant to the assessment endpoints. Fulton’s condition analysis also excluded adult fish assessed to be in a post-spawn (spent) state. Data from previous years were re-analyzed with juvenile fish and post-spawn adult excluded; data collected prior to 2024 were omitted as sexual maturity or life stage was not

reliably documented in those years rendering those records unsuitable for consistent evaluation across sampling periods.

10.3 RESULTS AND DISCUSSION

Results of the 2025 Rainbow Trout Spring Spawner program, including measurement endpoints and sampling sites under both the AEMP Plan (ERM 2025b) and the FUP for Condition 3.14, are provided in the *2025 Rainbow Trout Spawner Report* (Appendix E-4). Figures presenting adult rainbow trout captures by migration directions, with mean daily water temperatures and discharge are presented within the body of that report. The site and survey information, field water quality data and fish sampling effort recorded at each site, individual fish data including Fulton's conditions, and fish aging results are provided within the appendices of that report. Comparisons to previous years are provided below, where applicable.

Cumulatively, 6,668.6 hours of sampling effort across all sites resulted in the capture of 2,196 fish (1,187 adult and 1,080 juvenile rainbow trout, and 16 incidental species including mountain whitefish, northern pikeminnow and prickly sculpin). A total of 71 fish mortalities were recorded during sampling across all sites; the number of mortalities detailed by site, species, and observed cause are provided in the *2025 Rainbow Trout Spawner Report* (Appendix E-4).

Although the aim is to maintain consistent field methods over time, the capture approach (transitioning from hoop nets to box traps), as well as the timing and duration of the rainbow trout spawning surveys have varied substantially among years; these changes are summarized in Table 10.3-1. Given the inconsistency in the timing and duration of these surveys from 2011 to 2025, the ability to compare data across years is limited. Recognizing the limitations created by past variability, future monitoring will follow the field methodology employed in 2025 and the AEMP Implementation Framework to support reliable year-to-year comparisons. Furthermore, no adjustments to the capture methodology are planned, following the successful implementation of separated box traps in 2025.

TABLE 10.3-1 RAINBOW TROUT CAPTURE METHODOLOGY, TIMING, AND DURATION, 2011 TO 2025

Site	Year	Methodology	Timing	Effort – Soak Time (hours)[a]
TC-15	2011	Bi-directional hoop nets	June 9 to 28	502 (21)
	2022	Bi-directional hoop nets	June 9 to 28	908.3 (37.8)
	2023	Bi-directional box traps in rigid fish fence; box trap wall constructed with 1-inch mesh	May 10 to June 11	1,624.6 (67.7)
	2024	Bi-directional box traps in rigid fish fence; box trap wall constructed with 1-inch mesh	April 24 to June 16	2,530.1 (105.4)
	2025	Bi-directional box traps in rigid fish fence; box trap wall constructed with 1-inch mesh	May 1 to June 12	2,011.95 (83.83)

Site	Year	Methodology	Timing	Effort – Soak Time (hours)[a]
DC-20	2011	Bi-directional hoop nets	June 10 to 28	430 (18)
	2021	Bi-directional box traps in rigid fish fence; box trap walls constructed with ¼" mesh	June 17 to 30	536.2 (22.4)
	2022	Bi-directional hoop nets	June 25 to 28	151.8 (6.3)
	2023	Bi-directional box traps in rigid fish fence; box trap walls constructed with 1" mesh; additional hoop net	May 22 to June 23	1,486.1 (62)
	2024	Bi-directional box traps in rigid fish fence; box trap walls constructed with 1" mesh	April 25 to June 17	2,538.54 (105.8)
	2025	Separate bi-directional box traps in rigid fish fences Box trap wall constructed with ½" mesh	April 23 to June 16	2,390.22 (99.6)
661-20	2011	Bi-directional hoop nets	June 8 to 27	453 (19)
	2022	Bi-directional hoop nets	June 11 to 28	774.1 (32.3)
	2023	Bi-directional box traps in rigid fish fence; box trap wall constructed with 1" mesh	May 27 to June 23	1,138 (47.4)
	2024	Bi-directional box traps in rigid fish fence; box trap wall constructed with 1" mesh	April 24 to June 21	2,721 (113.4)
	2025	Separate bi-directional box traps in rigid fish fences; box trap wall constructed with ½" mesh	April 25 to June 19	2,266.44 (94.4)

Note:
[a] Number of days provided in brackets.

10.3.1 ABUNDANCE

Total rainbow trout spawner abundances at each site in 2025 are provided in Table 10.3-2. Statistical analysis was not performed to compare the 2025 rainbow trout spawner abundance to previous years due to the changes in sampling duration, timing, and capture methodology described in the previous section. These methodological differences introduce variability that limits the possibility of direct comparison among years. Qualitatively, the total abundance of rainbow trout spawners in Davidson Creek was similar in 2024 and 2025; this is likely a result of the adjustment in timing and duration of surveys to encompass the entire duration of the spawning migration made in these years.

TABLE 10.3-2 RAINBOW TROUT SPAWNER ABUNDANCE, 2011 TO 2025

Site	Site Classification	Year	Total Abundance
TC-15	Control	2022[c]	98
		2023[c]	283
		2024	558
		2025	262

Site	Site Classification	Year	Total Abundance
DC-20	Impact	2021	46[a]
		2022	31[b]
		2023[c]	209
		2024	488
		2025	465
661-20	Impact	2022[c]	35
		2023[c]	176
		2024	199
		2025	396

Notes:
2011 captures not included as total rainbow trout captures reported in AMEC 2013a do not differentiate between life stage or spawning status.
[a] spawner catch reported in Palmer 2022.
[b] spawner catch reported in Palmer 2023.
[c] 2022 and 2023 total abundances tabulated based on available historical raw data.

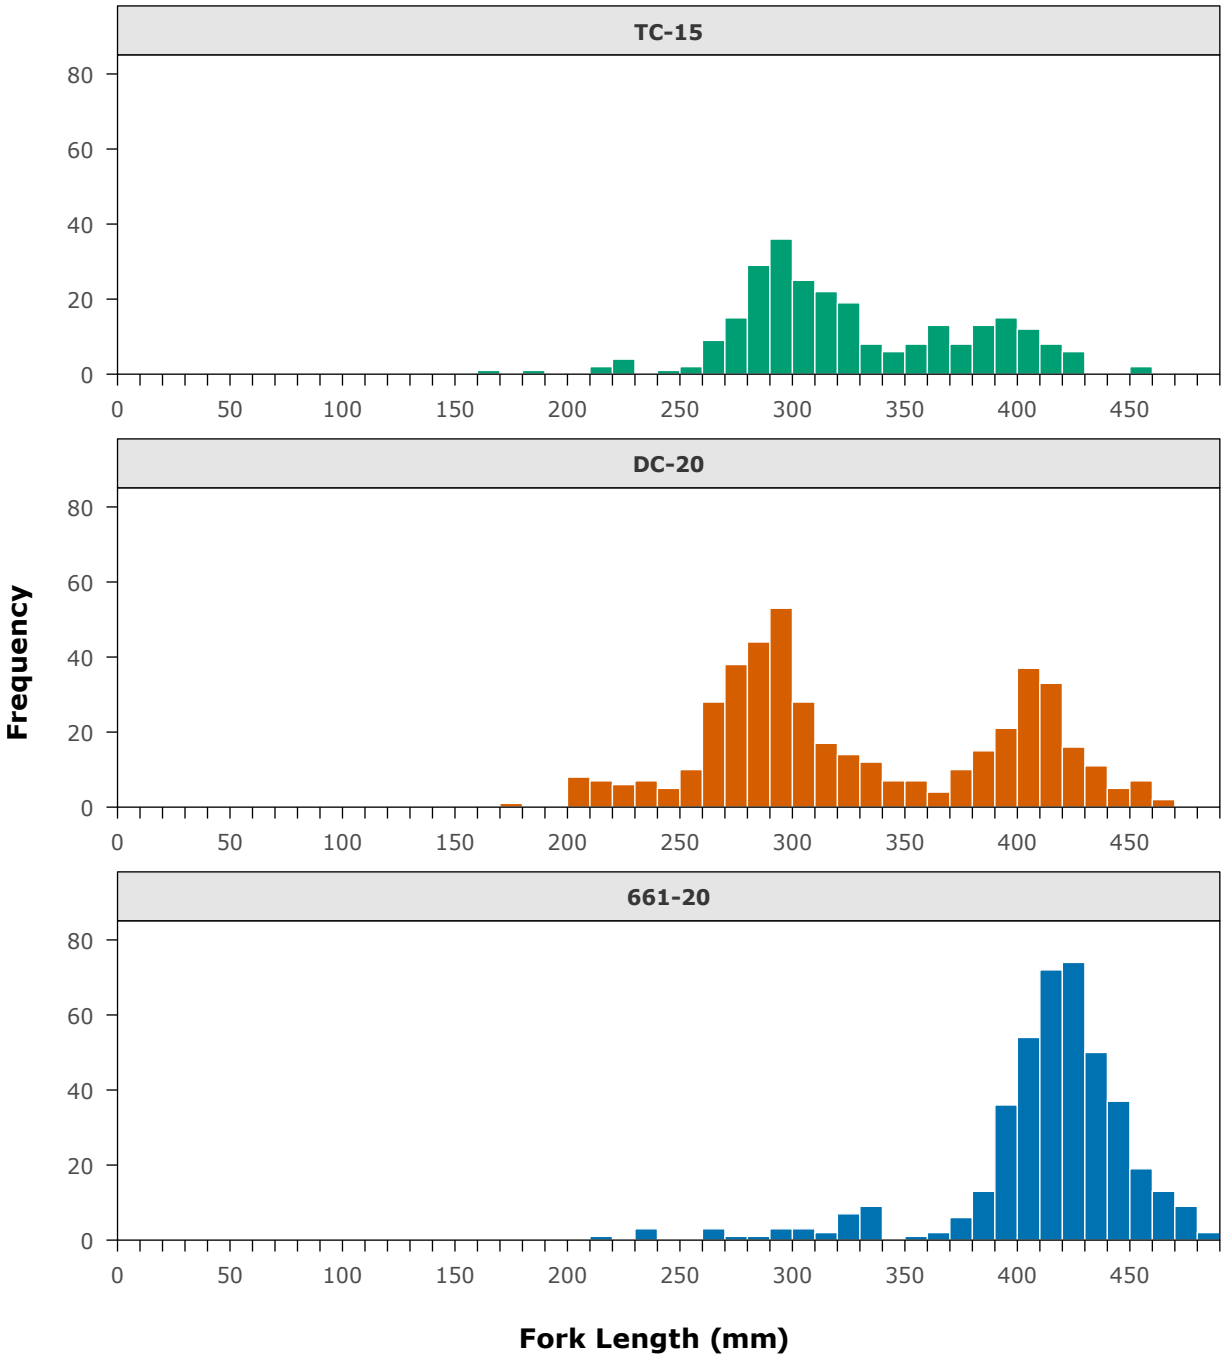
10.3.2 POPULATION STRUCTURE

Fork length of adult rainbow trout captured at AEMP spring spawning survey sites in 2025 ranged from 168 mm to 485 mm, while weight ranged from 52.2 g to 1544 g. In 2025, the length distribution of adult spawners at both impact sites (DC-20 and TC-15) differed significantly ($p < 0.05$) from the control site (TC-15), with adult spawners at the control site being generally smaller (Figure 10.3-1).

At TC-15, the distribution was multi-modal, with peaks near 230 mm, 300mm, 370 mm, and 410 mm, consistent with patterns observed in previous years. These modes represent at least four distinct age classes, which is supported by ageing results indicating fish between 4 and 7 years. At DC-20 there was a pronounced multi-modal structure, with peaks at approximately 200 to 240 mm, 300 mm, and 410 mm, representing at least three or more age classes within the spawning population. Ageing data from 2025 corroborate this interpretation, with fish ranging from 3 to 9 years. Although modes around 300 mm and 360 mm have been documented in previous years, the emergence of a distinct size class exceeding 400 mm in 2025 is new. At 661-20, the 2025 distribution similarly displayed multiple size modes, indicating several age classes, including a prominent group of adults around 430 mm. Although fish in this size range have been observed in previous years, they were far less common than the strong representation documented in 2025.

Taken together, these patterns suggest that all three sites supported multiple cohorts of spawning adults in 2025, but the relative abundance of larger, older fish differed among sites.

FIGURE 10.3-1 LENGTH-FREQUENCY DISTRIBUTIONS FOR ADULT RAINBOW TROUT SPAWNERS, IMPACT VS CONTROL SITES, 2025



Additionally, when compared among years, the length-frequency distributions at each site showed significant differences ($p < 0.001$). Given the adjustments in timing and duration of spawner surveys, some of these observed differences may also reflect variation in sampling timing or detectability among years; interpretation of length-frequency trends from earlier years should be done cautiously given the inconsistency of survey methodology.

Length-age linear regressions for adult rainbow trout captured at each site are presented in Figure 10.3-2. The difference in slope among the three sites was statistically significant ($p = 0.002$). There was significant difference in the slopes between impact site 661-20 and the control site TC-15 ($p = 0.003$), whereas there was no difference found between impact site DC-20 and TC-15 ($p = 0.390$). Growth rates were estimated as the linear slope of the length-age relationship. In 2025, adult rainbow trout at TC-15 exhibited the fastest growth (54 mm/year) whereas fish at 661-20 exhibited the slowest growth (38 mm/year). Since the assumption of parallel slopes was not met, an ANCOVA testing the difference of length-at-age among sites could not be conducted.

10.3.3 CONDITION

Mean Fulton's condition of adult rainbow trout captured in 2025 were similar among sites, ranging from 0.68 at site 661-20 to 1.92 at site TC-15 (Figure 10.3-3; Table 10.3-3). In 2025, there was no difference in mean condition of fish between DC-20 and TC-15. As a result of the large sample size, the small difference between condition at 661-20 and TC-15 was significant. Steel-Dwass multiple-comparison tests were also used to evaluate Fulton's condition of adult rainbow trout in 2024, restricting the dataset to only adult pre-spawn fish to allow for comparability with 2025 (Table 10.3-4; Table 10.3-5; Appendix E-5). Although statistically significant differences were detected among sites in this year, Fulton's condition of pre-spawn rainbow trout in these watercourses were essentially the same.

Gonadal development increases weight relative to length, causing gravid fish to exhibit an inflated Fulton's condition, while the deposition of eggs and milt during spawning reduces the weight of a post-spawn fish relative to its length leading to a smaller Fulton's condition. Any future analyses and interpretation of fish condition from baseline years should be made with caution given the variability introduced by sampling fish in both pre- and post-spawn stages.

TABLE 10.3-3 FULTON'S CONDITION OF RAINBOW TROUT SPAWNERS AND STATISTICAL COMPARISONS, 2025

Site	Site Classification	n	Mean ± SD	Impact vs Control	
				p	Percent Difference[a]

10.4 SUMMARY AND RECOMMENDATIONS

The 2025 rainbow trout Spring Spawning Survey indicates that rainbow trout populations remain healthy. Multi age cohorts, stable abundance between years, and consistent condition factors all support a conclusion of natural population dynamics. Given the adjustments in timing and duration of spawner surveys, some of these observed differences between baseline data and recent sampling years may reflect variation in sampling timing or detectability among years.

No additional sampling or analyses other than that described in the AEMP Plan (ERM 2025b) is recommended, with the following exception:

- Revise data analysis of Fulton's condition of adult rainbow trout spawners to standardize on a single reproductive state (i.e., gravid or pre-spawn condition). Restricting analyses to pre-spawn fish would minimize variability in Fulton's condition associated with post-spawning weight depletion.

11. AQUATIC EFFECTS MONITORING PROGRAM SUMMARY AND RECOMMENDATIONS

This AEMP Interpretive Report presents the results of the surface water quality sampling that was conducted during the monitoring period after construction and operations activities began (October 1, 2022 to December 31, 2025). The 2025 AEMP was implemented in accordance with AEMP Plan, Version 4.0 (ERM 2025b). Results of the 2025 sampling are summarized for surface water quality, chronic toxicity testing, sediment quality, aquatic resources, and benthic invertebrate and fish tissue in the following paragraphs in the context of the adaptive management framework for each of the monitored watersheds. Fish community inventory as well as rainbow trout and kokanee spawning were monitored in 2025 to assess potential Mine related effects and summarized below along with recommendations for incorporation into the next iteration of the AEMP Plan for implementation in 2026.

No changes to the surface water quality, chronic toxicity testing, sediment quality, aquatic primary producer community, and benthic invertebrate community and tissue monitoring components were recommended. However, changes to the statistical evaluation will be considered given there will be three years of post-baseline monitoring following the completion of the 2026 AEMP monitoring program. General linear models will be examined as a potential replacement of the BACI analysis given their flexibility in handling non-linear relationships and interactions. Non-compliance notices were received by the EAO (October 23, 2025) and the Independent Environmental Monitor (October 24, 2025) regarding the automated hydrometric stations identified in Section 4.3.2.1 of the AEMP Plan, Version 4.0 (ERM 2025b). Specifically, the non-compliance relates to telemetry at all hydrometric monitoring stations. Telemetry is not required at all stations except for DC-05, therefore the reference to telemetry loggers will be removed for all stream stations except for DC-05 in the next iteration of the AEMP Plan. The hydrometric program is not specific requirement of the AEMP, except to inform the analysis of effects (Condition 4.6 of PE 110652). However, the hydrometric program does have conditions that must be met on an annual basis as indicated in Condition 4.4 of PE 110652. Therefore, a separate hydrometric monitoring program (outside of the AEMP Plan as a separate standalone plan) will be considered in the next AEMP Plan.

Davidson Creek—The 2025 water quality at Davidson Creek sites indicated that most concentrations were similar or greater than baseline years and below levels of concern. Graphical analysis indicates concentrations of parameters that have increased when compared to baseline and when compared to predictions were likely related to the contribution of particulate-bound metals from overland flow from the 2023 fire-impacted upper Davidson Creek watershed to Davidson Creek (either directly or via non-contact water diversions), the water with high TSS released to Davidson Creek, and tree clearing activities adjacent to the upper Davidson Creek. Total iron (DC-05) and dissolved cobalt (DC-05, DC-10, DC-15) was considered to meet the “high” action level because the 2025 concentrations were higher than baseline concentrations and WQG-AL exceedances were observed in the same months. Graphical analysis indicates dissolved cobalt concentrations at Davidson Creek sites are likely associated with unrecovered seepage from the TSF C that was confirmed based on the groundwater monitoring results (KP 2026b).

No effects to aquatic life are expected given acute toxicity thresholds were met, and the magnitude of the total iron WQG-AL exceedances were low at DC-05 (range from 1.22 and 2.21 times the guideline for total iron). The magnitude of the dissolved cobalt exceedances at DC-05 and DC-10 in November and December 2025 (i.e., greater than four-times the guideline) if persistent, could have the potential for limited long-term effects to aquatic life. Examination of the toxicity data used to generate the dissolved cobalt WQG-AL suggests that the potential for long-term effects may be limited to the lower trophic levels (i.e., invertebrates and periphyton). Dissolved cobalt will continue to be monitored in accordance with regulatory requirements. BW Gold implemented mitigation measures to capture Mine-related sources downstream of the TSF C pond in late 2025 and early 2026 and is permitted to construct additional structures downstream of the present extent of Mine-related sources of water that are expected to provide further mitigation. BW Gold plans to commence construction of these structures in 2026. These mitigation measures are expected to positively impact water quality in future years. BW Gold continues to monitor the effectiveness of these actions. Results of September 2025 chronic toxicity testing, periphyton monitoring, and benthic invertebrate community monitoring at DC-05 do not suggest impairment in the lower trophic communities that could be associated with dissolved cobalt.

Sediment quality assessed at Davidson Creek sites indicate there were some increases from baseline consistent with natural enrichment or wildfire-related run-off in addition to the 2025 Mine activities. A “high” action level was exceeded for arsenic (DC-05 and DC-15), cadmium (DC-05, DC-15), and zinc (DC-05, DC-15). The elevated arsenic, cadmium, and zinc sediment concentrations at DC-05 and DC-15 are attributed to construction and operational activities since 2024.

Although sediment metal concentrations were greater than SQG-AL in 2025, the likelihood of adverse effects to aquatic life is low based on the overall level of exceedance remaining low (i.e., less than 5 times the guideline) that was confirmed with the observation of no significant alterations to the benthic communities and tissue metal concentrations in 2025. Runoff management and erosion and sediment control mitigations in response to turbid water entering Davidson Creek (either as unauthorized discharges or following exceedances of permit limits) will continue to mitigate future “high” action level exceedances.

The 2025 periphyton and benthic invertebrate communities did not represent large systematic shifts from baseline at impact sites in Davidson Creek. However, evaluation of periphyton biomass (as chlorophyll *a*) indicated the 2025 concentrations met the conditions of a “medium” action level indicating biomass are changing from baseline concentrations but are below levels of concern. The increase may be related to the increase in total phosphorus however sampling in 2025 also took place later in September than in previous years. As a result, no changes to the current mitigation measures are required. Like the water-quality changes observed in 2025, the nutrient changes (mainly total phosphorus) were likely related to the Mine activities, thus the same mitigation measures used for water quality also apply to nutrients.

The “low” action level for mercury in benthic invertebrate and fish tissue was met at DC-05 however the lack of statistically significant change from baseline and the absence of increasing trends at both Davidson Creek sites indicate that observed mercury concentrations are not at levels of concern. The 2025 fish tissue metal concentrations were similar to or lower when compared to baseline, with no Mine-related effects detected in streams or lakes. Mercury guideline

exceedances occurred at both impact and control sites, consistent with baseline patterns, while selenium remained below guidelines for all fish and sites sampled.

Creek 661—The results of the surface water quality monitoring at Creek 661 sites (661-03, 661-04, 661-05, 661-10, and 661-20) indicated that parameter concentrations were similar or greater than baseline concentrations and typically concentrations were below levels of concern. Graphical analysis indicated that most metals (total arsenic, barium, beryllium, cadmium, chromium, cobalt, copper, lead, manganese, uranium, and zinc, and dissolved manganese, and zinc) that were elevated at sites 661-04, 661-05 and 661-10 during Q1 of 2025 were attributed to 2025 construction activities and overland flow through the 2023 and 2024 fire-impacted areas around the Creek 661 tributaries located within the Mine site. Parameters meeting a "medium" action level with a significant increase when compared to baseline concentrations were total arsenic (661-04 and 661-05), total barium (661-04 and 661-05), total uranium (661-03, 661-04, 661-05, and 661-10), and dissolved zinc (661-04). Elevated total and dissolved copper, total and dissolved cadmium, and total and dissolved zinc were likely associated with dust or particle erosion following the ore stockpile dust event. BW Gold initiated mitigation measures in May 2025 in response to the dust event and water quality at Creek 661 sites in Q3 and Q4 were consistent with baseline concentrations indicating the effect was not persistent through 2025 and not likely to affect aquatic life during the highest period of productivity in late August/early September. A "high" action level was met for total aluminum (661-04, 661-05, and 661-10) and was most likely associated with 2025 construction activities and overland flow through the 2023 and 2024 fire-impacted areas around the Creek 661 tributaries located within the Mine site. Aluminum concentrations were similar to baseline later in the season therefore no aquatic effects to aquatic life were expected.

In the Creek 661 watershed, the WQG-AL were exceeded for total aluminum, total arsenic, total cadmium, total iron, dissolved iron, total mercury, and dissolved zinc. The annual frequency of exceedances and magnitude of exceedances of WQG-AL at stream sites were similar to baseline suggesting most exceedances are not related to construction activities and limited effects to aquatic life are expected and no additional mitigations are required.

Consistent with natural enrichment or wildfire-related run-off in addition to the 2025 Mine activities there were some increases in metals in the monitored Creek 661 sediments (cadmium, copper, lead, molybdenum, and zinc). Similar to Davidson Creek the water quality results suggest that effects of the wildfire and construction activities resulted in an increase in sediment metals. However, the elevated cadmium and zinc sediment concentrations at Creek 661 sites are also partly attributed to the ore stockpile dust event that occurred in Q1 of 2025. Erosion and sediment control mitigations and implementation of dust mitigations (planned and completed) as a result of the dust event will continue through the Operations period.

Although sediment metal concentrations were greater than SQG-AL in 2025, the likelihood of adverse effects to aquatic life is low based on the overall magnitude of exceedance remaining low (i.e., less than 5 times the guideline) that was confirmed with the observation of no significant alterations to the benthic communities and tissue metal concentrations. However, evaluation of periphyton biomass (as chlorophyll *a*) indicated the 2025 concentrations met the conditions of a

"medium" action level indicating biomass. The increase may be related to the short-term increases of total phosphorus in August and September 2025 that did not persist. Sampling also took place later in September than in previous years thus the light conditions were likely different and periphyton may have had longer to grow, resulting in higher biomass. Like the water-quality changes observed in 2025, the nutrient changes (mainly total phosphorus) were likely related to the Mine activities, thus the same mitigation measures used for water quality also apply to nutrients.

Chedakuz Creek—Water quality monitoring in Chedakuz Creek was completed upstream of Tatelkuz Lake (CC-03 and CC-05), downstream of Tatelkuz Lake (CC-10), and downstream of the confluence with Davidson Creek (CC-15, CC-20, CC-30, and CC-40). Statistically significant increases in pH, turbidity, sulphate, total ammonia-N, total aluminum, total barium, total iron, total and dissolved manganese, and total uranium tended to be at Chedakuz Creek sites downstream of the confluence with Davidson Creek (CC-15, CC-20, and CC-40 but not CC-30). It was concluded that greater concentrations of turbidity, total aluminum, and total barium at sites CC-15 and CC 20 may be related to 2024 and 2025 Mine activities (i.e., upstream of DC-20). However, it was concluded that the increasing concentrations at CC-40 are likely related to the anthropogenic sources that may contribute to Chedakuz Creek water quality and at site DC-20 (e.g., forest harvesting activities, road/trail networks, cattle grazing).

At Chedakuz Creek sites downstream of the Davidson Creek confluence (CC-15 and CC-20) there were exceedances of the total aluminum and dissolved iron WQG-AL. The YDWL standards were exceeded for pH, and dissolved manganese at site CC-15. The annual frequency of exceedances and magnitude of exceedances of the WQG-AL and YDWL standards at stream sites were similar to baseline suggesting most exceedances are not related to the Mine activities and limited effects to aquatic life are expected. Mitigation in response to Mine-related changes in water quality identified in Davidson Creek are expected to also address Mine-related increases in Chedakuz Creek.

In accordance with the AEMP Plan, aquatic resource, sediment quality, or fish tissue sampling was not completed in Chedakuz Creek to avoid damage or disruption to bed substrates in areas of Kokanee spawning habitat.

Turtle Creek—Turtle Creek sites are located in the watershed where the Mine airstrip would be located therefore an effects assessment was not completed for Turtle Creek sites because the airstrip has not been constructed.

Tatelkuz Lake—The 2025 Tatelkuz Lake (impact) and Kuyakuz Lake (control) water quality was similar to 2023 and 2024 and baseline monitoring years indicating no Mine-related effects. Tatelkuz Lake physical profiles (including baseline years) indicated that the lake was fully mixed in the winter and was usually stratified in the spring, summer, and fall (e.g., May, August, September, October, and November). Total and dissolved metals were low among all sites and frequently less than detection at all depths sampled. No exceedances of metal WQG-AL occurred at Tatelkuz Lake sites in 2025.

Fish Community Inventory, Kokanee Spawning, Kokanee Fry Outmigration and Rainbow Trout Spawning Surveys:

Fish community data collected at control and impact sites were summarized by CPUE, abundance and density estimates, population structure (length frequency distributions) and fish health. The 2025 fish community inventory analyses and results (comparison of control and impact and comparison to baseline) indicated no Mine-related effects. No changes to fish community and tissue monitoring or analyses is recommended, with the following exceptions for:

- Investigate potential locations for alternative regional control sites to replace the existing control sites TC-01 and 661-01, as both sites have failed repeatedly to produce fish captures that meet minimum sample size requirements for analyses. Augmenting the number of regional control sites, with comparable channel morphology and fish community composition, will improve the reliability of future analyses and strengthen the defensibility of effects assessments. Only Fish Community Inventory sampling would be conducted at alternative regional control sites, no additional tissue sampling for the analysis of metal is recommended.
- Include large gee-style cylinder traps as an additional capture method at site TC-05 during tissue sampling for the analysis of metals to better target rainbow trout. The life stages observed at this site—primarily larger juveniles and adults—are less likely to enter standard minnow traps, which can introduce size-selectivity and reduce capture success. Using both the smaller minnow traps and the larger cylinder traps may increase the likelihood of capturing the full range of rainbow trout present and improve catch rates needed to meet sample size requirements.

The kokanee summer spawning surveys monitored the size of kokanee spawning runs in the AEMP study area. Spawning success (measured as spawner and redd counts and density, and length at maturity) was assessed for effects related to changes in water quality related to construction activities. However, the insufficient number of years of spawning success data for each spawning run cohort, precluded assessment of potential Mine-related effects. No additional sampling or analyses were recommended for the Kokanee Summer Spawning Surveys with the following exceptions:

- Incorporation of an additional impact survey section (CC-05A2-KO) in Middle Chedakuz Creek. In August 2025, a one-time survey during peak spawning was conducted over the entire length of Middle Chedakuz Creek to fill knowledge gaps with respect to kokanee spawning habitat use and condition; results of that survey were reported under separate cover. Based on the recommendations within that report, the addition of CC-05A2-KO will help to improve statistical robustness and spatial representativeness of the kokanee spawner program.
- Alternative approaches to monitoring kokanee spawning habitat should be explored. In particular, incorporating detailed habitat surveys that quantify the extent and condition of high-use spawning areas would provide more reliable information for detecting habitat change. The current FHAP methodology, used to determine relative abundance of mesohabitat, is strongly influenced by observer interpretation and short-term environmental variability (e.g., flow, turbidity) resulting in low repeatability and inconsistent data across years. These limitations reduce the method’s ability to detect subtle or cumulative habitat changes associated with Mine effects, making it poorly suited for robust effects assessments.

Kokanee fry outmigration survey endpoints of total fry abundance for the outmigration period and fish health were assessed in 2025. Kokanee fry outmigration abundance estimates, derived from both mark-recapture trapping efficiency and area-based methods, were higher in 2025 compared to 2024 and 2023 estimates at all sites and may be related to the increased sampling frequency in 2025. Kokanee fry condition was within the natural variability at both impact and control sites. Egg-to-fry survival estimates for 2025 were calculated for Davidson Creek only. The limited number of years of available Kokanee fry data precluded assessment of potential Mine-related effects at this time. No additional sampling or analyses were recommended for the Kokanee Fry Spring Out Migration Survey with the following exceptions:

- Adjust the AEMP Implementation Framework commencement trigger by reducing the ATU threshold. Monitoring in 2025 indicates that Kokanee fry outmigration in Davidson Creek and Middle Chedakuz Creek occurs at a lower ATU value than the current trigger reflects. Lowering this threshold will support more accurate, watercourse-specific timing for sampling events.
- Update the egg-to-fry survival calculation to the method outlined in this report. Because this approach incorporates fish length as a variable, it likely provides a more accurate and representative estimate of egg production than relying solely on literature cited values.

Rainbow trout spring spawning survey data collected at control and impact sites were summarized by CPUE of spawners, population structure (length frequency distributions) and fish condition. The 2025 rainbow trout spawner survey analysis and results indicated no Mine-related effects and variability among years was likely related to timing and duration of the surveys completed each year. No additional sampling or analyses were recommended for the Rainbow Trout Spring Spawning Survey with the following exception:

- Revise data analysis of Fulton’s condition of adult rainbow trout spawners to standardize on a single reproductive state (i.e., gravid or pre-spawn condition). Restricting analyses to pre-spawn fish would minimize variability in Fulton’s condition associated with post-spawning weight depletion.

12. PLANNED AQUATIC EFFECTS MONITORING FOR 2026

The 2026 AEMP will be implemented in accordance with the AEMP Plan, Version 5.0 upon approval (Version 5.0 will be submitted for approval by April 30, 2026, in accordance with PE-110652, Condition 4.6.6). Monitoring is planned for the 2026 monitoring year at sites and frequencies identified in the AEMP Plan for the following AEMP components:

- Surface water quantity, quality, and chronic toxicity testing;
- Sediment quality testing;
- Aquatic primary producers;
- Aquatic benthic invertebrates and benthic invertebrate tissue metal sampling; and
- Fish community, fish spawning, and fish tissue metal sampling.

The 2026 AEMP Interpretive Report will provide an evaluation of the potential effects of operations and construction activities (October 2022 to December 2026).

APPENDIX A SURFACE WATER QUALITY RESULTS

APPENDIX A-1	2025 STREAM WATER QUALITY LABORATORY RESULTS, BLACKWATER MINE
APPENDIX A-2	2025 STREAM WATER QUALITY FIELD DATA, BLACKWATER MINE
APPENDIX A-3	2025 LAKE WATER QUALITY LABORATORY RESULTS, BLACKWATER MINE
APPENDIX A-4	2025 LAKE WATER QUALITY FIELD DATA, BLACKWATER MINE
APPENDIX A-5	2025 SURFACE WATER QUALITY QUALITY ASSURANCE AND QUALITY CONTROL RESULTS, BLACKWATER MINE
APPENDIX A-6	SUMMARY OF 2025 STREAM AND LAKE WATER QUALITY
APPENDIX A-7	2016 TO 2025 MONTHLY MEAN STREAM WATER QUALITY GRAPHS
APPENDIX A-8	2016 TO 2025 MONTHLY MEAN STREAM FIELD PARAMETERS GRAPHS
APPENDIX A-9	2021 TO 2025 MONTHLY MEAN LAKE WATER QUALITY GRAPHS
APPENDIX A-10	2021 TO 2025 MONTHLY MEAN LAKE FIELD PARAMETER PROFILES
APPENDIX A-11	COMPARISON OF MEAN MONTHLY WATER QUALITY (OCTOBER 2022 TO DECEMBER 2025) AND 95TH PERCENTILE BASELINE + 20% (2016 TO SEPTEMBER 2022) FOR DAVIDSON CREEK, CREEK 661, AND CHEDUKUZ CREEK SITES
APPENDIX A-11A	COMPARISON OF AVERAGE MONTHLY WATER QUALITY AND BASELINE FOR DC-05 IN DAVIDSON CREEK
APPENDIX A-11B	COMPARISON OF AVERAGE MONTHLY WATER QUALITY AND BASELINE FOR DC-10 IN DAVIDSON CREEK
APPENDIX A-11C	COMPARISON OF AVERAGE MONTHLY WATER QUALITY AND BASELINE FOR DC-15 IN DAVIDSON CREEK
APPENDIX A-11D	COMPARISON OF AVERAGE MONTHLY WATER QUALITY AND BASELINE FOR DC-20 IN DAVIDSON CREEK
APPENDIX A-11E	COMPARISON OF AVERAGE MONTHLY WATER QUALITY AND BASELINE FOR 661–03 IN CREEK 661
APPENDIX A-11F	COMPARISON OF AVERAGE MONTHLY WATER QUALITY AND BASELINE FOR 661–04 IN CREEK 661
APPENDIX A-11G	COMPARISON OF AVERAGE MONTHLY WATER QUALITY AND BASELINE FOR 661–05 IN CREEK 661
APPENDIX A-11H	COMPARISON OF AVERAGE MONTHLY WATER QUALITY AND BASELINE FOR 661–10 IN CREEK 661
APPENDIX A-11I	COMPARISON OF AVERAGE MONTHLY WATER QUALITY AND BASELINE FOR 661–20 IN CREEK 661

APPENDIX A-11J	COMPARISON OF AVERAGE MONTHLY WATER QUALITY AND BASELINE FOR CC-15 IN CHEDAKUZ CREEK
APPENDIX A-11K	COMPARISON OF AVERAGE MONTHLY WATER QUALITY AND BASELINE FOR CC-20 IN CHEDAKUZ CREEK
APPENDIX A-11L	COMPARISON OF AVERAGE MONTHLY WATER QUALITY AND BASELINE FOR CC-30 IN CHEDAKUZ CREEK
APPENDIX A-11M	COMPARISON OF AVERAGE MONTHLY WATER QUALITY AND BASELINE FOR CC-40 IN CHEDAKUZ CREEK
APPENDIX A-12	2025 SURFACE WATER QUALITY RESULTS OF THE BEFORE-AFTER-CONTROL-IMPACT ANALYSIS
APPENDIX A-13	COMPARISON OF MEAN MONTHLY WATER QUALITY (OCTOBER 2022 TO DECEMBER 2025) AND PREDICTED WATER QUALITY FOR DAVIDSON CREEK, CHEDAKUZ CREEK, AND CREEK 661 SITES
APPENDIX A-13A	COMPARISON OF AVERAGE MONTHLY WATER QUALITY AND PREDICTED WATER QUALITY FOR DC-05 IN DAVIDSON CREEK
APPENDIX A-13B	COMPARISON OF AVERAGE MONTHLY WATER QUALITY AND PREDICTED WATER QUALITY FOR DC-10 IN DAVIDSON CREEK
APPENDIX A-13C	COMPARISON OF AVERAGE MONTHLY WATER QUALITY AND PREDICTED WATER QUALITY FOR DC-15 IN DAVIDSON CREEK
APPENDIX A-13D	COMPARISON OF AVERAGE MONTHLY WATER QUALITY AND PREDICTED WATER QUALITY FOR DC-20 IN DAVIDSON CREEK
APPENDIX A-13E	COMPARISON OF AVERAGE MONTHLY WATER QUALITY AND PREDICTED WATER QUALITY FOR 661–05 IN CREEK 661
APPENDIX A-13F	COMPARISON OF AVERAGE MONTHLY WATER QUALITY AND PREDICTED WATER QUALITY FOR 661–10 IN CREEK 661
APPENDIX A-13G	COMPARISON OF AVERAGE MONTHLY WATER QUALITY AND PREDICTED WATER QUALITY FOR 661–20 IN CREEK 661
APPENDIX A-13H	COMPARISON OF AVERAGE MONTHLY WATER QUALITY AND PREDICTED WATER QUALITY FOR CC-10 IN CHEDAKUZ CREEK
APPENDIX A-13I	COMPARISON OF AVERAGE MONTHLY WATER QUALITY AND PREDICTED WATER QUALITY FOR CC-15 IN CHEDAKUZ CREEK
APPENDIX A-13J	COMPARISON OF AVERAGE MONTHLY WATER QUALITY AND PREDICTED WATER QUALITY FOR CC-20 IN CHEDAKUZ CREEK
APPENDIX A-14	WATER QUALITY BENCHMARKS FOR ALL SITES BASED ON WATER QUALITY GUIDELINES FOR THE PROTECTION OF AQUATIC LIFE, WILDLIFE, AND AGRICULTURE (LIVESTOCK)
APPENDIX A-15	2025 SURFACE WATER CHRONIC TOXICITY TESTING RESULTS, BLACKWATER MINE

Appendix A-1 2025 Stream Water Quality Laboratory Results, Blackwater Mine

APPENDIX A-1: 2025 STREAM WATER QUALITY LABORATORY RESULTS, BLACKWATER MINE

Notes:
'-' indicates parameter was not analyzed.
'<' indicates value was below the detection limit.
[a] Value was identified as an outlier and excluded from the AEMP dataset for all data analyses.

Appendix A-5 2025 Quality Assurance and Quality Control Results, Blackwater Mine

Appendix A-5: 2025 Surface Water Quality Quality Assurance and Quality Control, Blackwater Mine

After delivery of the samples to the CALA-certified laboratory (ALS Environmental, Burnaby BC; ALS), a review of the sample receipt confirmation was completed to identify any issues that may have occurred during transport to the laboratory. Instances of sample integrity issues noted on the sample receipt confirmations from ALS were addressed in coordination with the laboratory as applicable to ensure accurate and complete analyses of surface water samples. For example, if glass containers were broken in transit or particles were observed inside the dissolved nutrient containers the requested analyses were completed from using a subsample of water from another appropriate sample collection bottle if applicable and instances of containers not labeled properly or discrepancies in requested analyses and received containers were resolved. Any occurrence where analyses were not completed as requested based on missed sample bottles did not impact the analysis of effects of data integrity.

1. FIELD AND TRAVEL BLANKS

Except for pH, concentrations of water quality parameters are expected to be less than the detection limit (DL) in field and travel blanks. Measured parameters greater than the DL in field blanks represent potential sample contamination during sample preservation or contamination during field blank preparation. Measured parameters greater than the DL in travel blanks potentially represent contamination of samples in transit, contamination during laboratory analysis, or contamination during travel blank preparation.

Forty field blanks and 44 travel blanks were included in the 2025 surface water quality sampling program (Table A5-1). Detectable values of acidity were measured in 75% of the field and 68% of the travel blanks with detectable values being equal to or 1.3 times greater than the DL (2 mg/L). Detections of acidity are common in the field and travel blanks, which reflects dissolved carbon dioxide in the laboratory supplied water and not sample contamination. Overall, other detectable concentrations were rarely observed (<1% of the 8,010 observations) in the field (12 detections) and travel (7 detections) blanks. All detectable field blank observations, except for one, were less than five times the DL (i.e., within the range of analytical variability): three total alkalinity (1.2 to 1.4 times), six ammonia (1.2 to 2 times), one thiocyanate (1.1 times), and one dissolved aluminum (4.4 times); and one dissolved tin detection that was 8.5 times the DL. Travel blank detections were all less than five times the DL: two total alkalinity (1 and 1.1 times), one nitrite (1.1 times), one thiocyanate (1.1 times), one total chromium (1.4 times) one total manganese (1.3 times), and one dissolved aluminum (equal to the DL). The field and travel blanks results indicate that the field sampling and handling procedures were successful at mitigating sample contamination.

At the start of each lake sampling event, for each water sampler used an equipment blank was collected from the water sampler prior to collecting lake water quality samples. In 2025, five equipment blanks were collected. Similar to the field and travel blanks, detectable concentrations for acidity were measured in 60% of the equipment blanks and equal to or 1.2 times greater than the DL. Other detectable concentrations were infrequent in the

equipment blanks (3% of 450 observations) and all observations were less than five times the DL. Equipment blank detections included: one total aluminum, one total zinc, and one dissolved copper observation (1.1 to 1.5 times the DL); all (five) total manganese (1.4 to 2.2 times the DL); three dissolved manganese (1 to 3 times the DL); and four dissolved zinc observations (1.2 to 3.5 times the DL).

2. FIELD DUPLICATES

The RPD results for stream and lake water quality field duplicates are presented in Tables A5-1 and A5-2.

A total of 53 field duplicates were collected at stream sites and 1,883 RPDs were calculated. Of the calculated RPDs, 2.6% (n = 48) were in the range of 20% to 50%, and 1.1% (n = 21) were greater than 50% (Table A5-1). There were 18 parameters with an RPD between 20% and 50%: total alkalinity, conductivity, turbidity, total Kjeldahl nitrogen, total phosphorus, dissolved Ortho-phosphorus, total organic carbon, total aluminum, total barium, total cobalt, total iron, total manganese, total titanium, total uranium, dissolved aluminum, dissolved manganese, dissolved molybdenum and dissolved titanium. The RPDs between 20 and 50% most frequently occurred for total (17%) and dissolved (13%) aluminum and the remaining parameters contributed 2% to 8%. Parameters with RPDs higher than 50% included: nitrate-N, total phosphorus, total aluminum, total iron, total manganese, total titanium, dissolved barium, and dissolved manganese. The RPDs higher than 50% occurred most frequently for total manganese (29%) and total aluminum (24%), and total iron (19%). Overall, there were no clear temporal and spatial patterns in the RPD calculations greater than 20%. Calculated RPDs between 20% and 50% were present in duplicates collected in each month (3% to 13%), with the exception of December when no RPD was greater than 20%. The RPDs greater than 50% were mostly observed in September (43%), August (14%), November (14%), and December (15%) and occasionally in April, May, and October (5% each). The RPDs between 20% and 50% occurred infrequently (≤10%) at sites 661-01, 661-04, 661-10, 705-05, 705-10, CC-03, CC-05, CC-20, CC-30, CC-40 and 661-20 and more frequently in CC-15 (21%), DC-05 (15%), and DC-20 (15%). The majority (38%) of RPDs greater than 50% occurred at site 661-01 on September 24 and 30. Sites DC-15, DC-20, and 661-20 each accounted for 14% frequency of the RPDs greater than 50% and more infrequently 661-10, 705-10, CC-15, and DC-05 accounted for 5% each.

A total of three field duplicates were collected at lake sites and 97 RPDs were calculated (Table A5-2). Of the calculated RPDs, 1 observation was in the range of 20% to 50% and 1observation was greater than 50%. For the primary and duplicate sample KL-01 deep on February 5, 2025, the nitrate-N RPD was 20% and total phosphorus RPD was 51%.

Although there was some minor heterogeneity of water collected, this is typical of natural water bodies and the field duplicate results indicate that sample collection was reproducible, and the water samples collected during the reporting period were representative of the waterbodies at the time of sampling.

3. LABORATORY

Samples were generally analyzed within their recommended holding times, excluding those parameters with short holding times (e.g., 3 days), which can be logistically challenging to analyze in time for remote projects. Sample exceptions to holding times for 2025 include February equipment blank on workorder VA25A3595, due to personnel error, and February samples 661-10 and 661-05 on workorder VA25A4211 and June samples CC-15, CC-20, CC-40, 705-10, and a travel blank (TB7-WS) on workorder VA25B3822 that were delayed due to logistical errors made by the shipping company. In February, three of the five samples (661-20, CC-03, and CC-05) were discarded and resampled, but two site samples were analyzed (661-10 and 661-05) because the field team was unable to collect more samples due to it being the end of the month. In June, the samples and the travel blank had two additional parameters (total suspended solids and total dissolved solids) exceeding their recommended holding time of 7 days. This is not expected to affect the results, because these hold times are considered conservative, and the reliability of the samples was evaluated with the other field and laboratory QA/QC.

Overall, the laboratory data quality objectives for internal QA/QC were met, and the laboratory reports were issued and distributed without further comment. In some cases, the laboratory noted issues with method blanks, matrix spikes, and laboratory replicates. For method blanks, results were considered reliable if the associated samples were either below detection limits, or greater than five times the concentration detected in the method blanks. For laboratory QA/QC results that were flagged against the laboratory's data quality objectives, results for associated samples, and corresponding field and travel blanks when available, were reviewed against the method blanks, matrix spikes, and laboratory replicate results and it was concluded that reported data was reliable and influence on the sample results and the ability to detect potential Mine-related effects would have been negligible.

Certificates of Analysis, including complete results from laboratory QA/QC checks, can be made available on request.

4. OUTLIERS

Outliers were identified for removal following review of the 2025 surface water quality based on QA/QC results, professional judgement, and other supporting information (e.g., graphical analysis, summary statistics).

For field measurements, the following 2025 erroneous values (i.e., outliers as a result of operator error or probe issues) were removed from the data analysis:

- TC-10, 03 February 2025, field pH = 1.44 pH units;
- 661-10, 10 March 2025, field conductivity = 53,100 µS/cm;
- 661-01, 11 May 2025, field conductivity = 106 µS/cm;
- 661-10, 11 May 2025, field conductivity = 189 µS/cm;
- DC-05, 11 May 2025, field conductivity = 290 µS/cm;
- DC-15, 11 May 2025, field conductivity = 361 µS/cm; and
- TC-10, 13 May 2025, field conductivity = 16.8 µS/cm.

For laboratory measurements, one total zinc result was removed from the data analysis for sample 661-01 on 13 October 2025 (ALS Sample ID: VA25C7416-001; value = 0.0848 mg/L). The removed result is suspected to be an erroneous value; the removed value was over 28-times the DL when all other observed total zinc concentrations for site 661-01 were less than the DL (0.003 mg/L) in 2025, and there as no indication of potential sources of contamination based on review of the associated sampling event blanks, laboratory QA/QC results, and other parameters (e.g., total suspended solids and other total metals).

TABLE A5-1 SURFACE WATER QUALITY EQUIPMENT, FIELD, AND TRAVEL BLANKS, BLACKWATER MINE, 2025

Notes:
'-' indicates parameter was not analyzed.
'<' indicates value was below the detection limit.
Gray shading indicates value was equal to or greater than detection limit.

Notes:
'-' indicates parameter was not analyzed.
'<' indicates value was below the detection limit.
Gray shading indicates value was equal to or greater than detection limit.

Notes:
'-' indicates parameter was not analyzed.
'<' indicates value was below the detection limit.
Gray shading indicates value was equal to or greater than detection limit.

Notes:
'-' indicates parameter was not analyzed.
'<' indicates value was below the detection limit.
Gray shading indicates value was equal to or greater than detection limit.

Notes:
'-' indicates parameter was not analyzed.
'<' indicates value was below the detection limit.
Gray shading indicates value was equal to or greater than detection limit.

Notes:
'-' indicates parameter was not analyzed.
'<' indicates value was below the detection limit.
Gray shading indicates value was equal to or greater than detection limit.

Notes:
'-' indicates parameter was not analyzed.
'<' indicates value was below the detection limit.
Gray shading indicates value was equal to or greater than detection limit.

Notes:
DL = Detection Limit; RPD = Relative Percent Difference
'-' indicates RPD was not computed because one or both concentrations were less than 5 times the detection limit.
'<' indicates value was below the detection limit.
Light gray shading indicates RPD was between 20 and 50%; dark gray shading indicates RPD was greater than 50%.

Notes:
DL = Detection Limit; RPD = Relative Percent Difference
'-' indicates RPD was not computed because one or both concentrations were less than 5 times the detection limit.
'<' indicates value was below the detection limit.
Light gray shading indicates RPD was between 20 and 50%; dark gray shading indicates RPD was greater than 50%.

Notes:
DL = Detection Limit; RPD = Relative Percent Difference
'-' indicates RPD was not computed because one or both concentrations were less than 5 times the detection limit.
'<' indicates value was below the detection limit.
Light gray shading indicates RPD was between 20 and 50%; dark gray shading indicates RPD was greater than 50%.

Notes:
DL = Detection Limit; RPD = Relative Percent Difference
'-' indicates RPD was not computed because one or both concentrations were less than 5 times the detection limit.
'<' indicates value was below the detection limit.
Light gray shading indicates RPD was between 20 and 50%; dark gray shading indicates RPD was greater than 50%.

Notes:
DL = Detection Limit; RPD = Relative Percent Difference
'-' indicates RPD was not computed because one or both concentrations were less than 5 times the detection limit.
'<' indicates value was below the detection limit.
Light gray shading indicates RPD was between 20 and 50%; dark gray shading indicates RPD was greater than 50%.

Notes:
DL = Detection Limit; RPD = Relative Percent Difference
'-' indicates RPD was not computed because one or both concentrations were less than 5 times the detection limit.
'<' indicates value was below the detection limit.
Light gray shading indicates RPD was between 20 and 50%; dark gray shading indicates RPD was greater than 50%.

Notes:
DL = Detection Limit; RPD = Relative Percent Difference
'-' indicates RPD was not computed because one or both concentrations were less than 5 times the detection limit.
'<' indicates value was below the detection limit.
Light gray shading indicates RPD was between 20 and 50%; dark gray shading indicates RPD was greater than 50%.

Notes:
DL = Detection Limit; RPD = Relative Percent Difference
'-' indicates RPD was not computed because one or both concentrations were less than 5 times the detection limit.
'<' indicates value was below the detection limit.
Light gray shading indicates RPD was between 20 and 50%; dark gray shading indicates RPD was greater than 50%.

Notes:
DL = Detection Limit; RPD = Relative Percent Difference
'-' indicates RPD was not computed because one or both concentrations were less than 5 times the detection limit.
'<' indicates value was below the detection limit.
Light gray shading indicates RPD was between 20 and 50%; dark gray shading indicates RPD was greater than 50%.

Notes:
DL = Detection Limit; RPD = Relative Percent Difference
'-' indicates RPD was not computed because one or both concentrations were less than 5 times the detection limit.
'<' indicates value was below the detection limit.
Light gray shading indicates RPD was between 20 and 50%; dark gray shading indicates RPD was greater than 50%.

Notes:
DL = Detection Limit; RPD = Relative Percent Difference
'-' indicates RPD was not computed because one or both concentrations were less than 5 times the detection limit.
'<' indicates value was below the detection limit.
Light gray shading indicates RPD was between 20 and 50%; dark gray shading indicates RPD was greater than 50%.

Notes:
DL = Detection Limit; RPD = Relative Percent Difference
'-' indicates RPD was not computed because one or both concentrations were less than 5 times the detection limit.
'<' indicates value was below the detection limit.
Light gray shading indicates RPD was between 20 and 50%; dark gray shading indicates RPD was greater than 50%.

Notes:
DL = Detection Limit; RPD = Relative Percent Difference
'-' indicates RPD was not computed because one or both concentrations were less than 5 times the detection limit.
'<' indicates value was below the detection limit.
Light gray shading indicates RPD was between 20 and 50%; dark gray shading indicates RPD was greater than 50%.

Notes:
DL = Detection Limit; RPD = Relative Percent Difference
'-' indicates RPD was not computed because one or both concentrations were less than 5 times the detection limit.
'<' indicates value was below the detection limit.
Light gray shading indicates RPD was between 20 and 50%; dark gray shading indicates RPD was greater than 50%.

Notes:
DL = Detection Limit; RPD = Relative Percent Difference
'-' indicates RPD was not computed because one or both concentrations were less than 5 times the detection limit.
'<' indicates value was below the detection limit.
Light gray shading indicates RPD was between 20 and 50%; dark gray shading indicates RPD was greater than 50%.

Notes:
DL = Detection Limit; RPD = Relative Percent Difference
'-' indicates RPD was not computed because one or both concentrations were less than 5 times the detection limit.
'<' indicates value was below the detection limit.
Light gray shading indicates RPD was between 20 and 50%; dark gray shading indicates RPD was greater than 50%.

Notes:
DL = Detection Limit; RPD = Relative Percent Difference
'-' indicates RPD was not computed because one or both concentrations were less than 5 times the detection limit.
'<' indicates value was below the detection limit.
Light gray shading indicates RPD was between 20 and 50%; dark gray shading indicates RPD was greater than 50%.

Notes:
DL = Detection Limit; RPD = Relative Percent Difference
'-' indicates RPD was not computed because one or both concentrations were less than 5 times the detection limit.
'<' indicates value was below the detection limit.
Light gray shading indicates RPD was between 20 and 50%; dark gray shading indicates RPD was greater than 50%.

Notes:
DL = Detection Limit; RPD = Relative Percent Difference
'-' indicates RPD was not computed because one or both concentrations were less than 5 times the detection limit.
'<' indicates value was below the detection limit.
Light gray shading indicates RPD was between 20 and 50%; dark gray shading indicates RPD was greater than 50%.

Appendix A-6 Summary of 2025 Stream and Lake Water Quality

3.	REFERENCES	12

Characterization of the 2025 water quality for the AEMP monitored streams and lakes is provided below. Differences between the baseline and construction sampling period were noted but the evaluated parameters for impact sites in 2025 (i.e., impact sites in Davidson Creek, Creek 661, Chedakuz Creek, and Tatelkuz Lake) are compared to baseline, model predictions, and water quality guidelines, as applicable, to assess Mine-related effects in Section 2.3 of the main report.

1. STREAM SURFACE WATER QUALITY SUMMARY

The AEMP monitored sites were grouped as follows for graphing and discussion purposes:

- Davidson Creek watershed (DC-05, DC-10, DC-15, and DC-20);
- Creek 661 watershed (661-01, 661-10, and 661-20 on Creek 661 mainstem; 661-03 on Creek 543585; 661-04 on Creek 146920; and 661-05 on Creek 505659);
- Chedakuz Creek watershed (CC-03 and CC-05 on Upper Chedakuz Creek; and CC-10, CC-15, CC-20, CC-30, and CC-40 on Lower Chedakuz Creek);
- Turtle Creek watershed (TC-01, TC-05, TC-10, and TC-15); and
- Regional control sites (705-05, 705-10, and FC-01).

The AEMP streams have generally been monitored monthly since 2017 (baseline). The Construction period was October 2022 to January 2025 when Operations began.

Timeseries graphs for monthly mean concentration of each parameters analyzed by the laboratory are provided in Appendix A-7. Stream field parameters graphs presenting monthly comparisons of the baseline, Construction, and Operations periods for pH, temperature, turbidity, conductivity, and dissolved oxygen are provided in Appendix A-8.

Exceedances of British Columbia (BC) or federal Water Quality Guidelines for the Protection of Aquatic Life (WQG-AL), approved science-based environmental benchmarks (SBEBs), and the Yinka Dene Water Law (YDWL) water quality standards are indicated (BC WLRS 2025a, 2025b; CCME 2025).

1.1 PHYSICAL PARAMETERS

1.1.1 PH AND ALKALINITY

Stream sites were typically near-neutral to moderately alkaline, with laboratory pH ranging from 6.82 (661-01 in May) to 8.69 (CC-10 in August; Figure A7-1) and field pH similarly ranging from 6.68 (705-05 in June) to 9.13 (CC-10 in August; Figures A8-1, A8-2, A8-3, A8-4, and A8-5). Most stream sites had a low sensitivity to acid inputs (total alkalinity >20 mg/L as $CaCO_3$) throughout the year, except for site 661-01 which ranged from 6.0 to 17.9 mg/L as $CaCO_3$ and had a moderate to high sensitivity to acid inputs (Figure A7-3). Alkalinity was seasonally variable in monitored streams and was typically inversely related to stream flows; the lowest mean alkalinity values were measured during freshet in May. At most sites, pH and alkalinity values observed during in 2025 were typically within the range observed during baseline years.

Laboratory-measured pH was within the BC WQG-AL range of 6.5 to 9 pH units in 2025 for all samples (Figure A7-1). One laboratory-measured pH value was greater than the proposed pH YDWL standard at Chedakuz Creek site CC-15 in August 2025 (YDWL standard upper range value = 8.1). Field measured pH in 2025 was within the BC WQG-AL range for all samples with the exception of CC-10 in August (9.13 pH units; Figures A8-1a, A8-2a, A8-3a, A8-4a, and A8-5a).

1.1.2 HARDNESS

Throughout the year in 2025 and similar to baseline observations, stream hardness was typically: soft (<60 mg/L as $CaCO_3$) at all regional control sites, Davidson Creek sites, Creek 661 sites except for 661-20 and moderately hard (61 to 120 mg/L as $CaCO_3$) at site 661-20 in Creek 661 and all Chedakuz and Turtle Creek sites (Figure A7-4). Upstream site CC-03 in Chedakuz had hard water (<120 mg/L as $CaCO_3$) in some months (e.g., January, February, September, and December). Hardness concentrations followed a similar spatial and temporal pattern to alkalinity; hardness concentrations were lowest during freshet and highest during low flow winter months.

Hardness values observed in 2025 were typically within the range observed during baseline years at all monitored sites.

1.1.3 SUSPENDED MATERIAL

Total suspended solids and turbidity (laboratory and field) were typically low in monitored streams in 2025 except for freshet and fall rains (Figures A7-5, A7-6, A8-1c, A8-2c, A8-3c, A8-4c, and A8-5c). Suspended material was associated with the hydrological regime, with TSS generally below the detection limit (DL) and relatively elevated TSS concentrations corresponding to elevated stream flows in April through June, depending on the year, representing freshet. Total suspended solids and turbidity were typically low in streams in 2025, with an average of 2.5 mg/L and a max of 47.9 mg/L for TSS and an average of 2.52 NTU and a max of 24.8 NTU (661-05 in April) for turbidity. Field-measured turbidity was similar in 2025, with an average of 2.58 NTU and a max of 22.3 NTU (661-05 in April). TSS observed in 2025 at monitored sites were within the range of baseline values. Laboratory turbidity values were higher than the baseline range at Davidson Creek and Creek 661, turbidity was not measured in the field during baseline years.

1.1.4 TOTAL DISSOLVED SOLIDS

Total dissolved solids generally followed the same pattern as hardness and alkalinity (Figure A7-7). Lower TDS values during freshet and other high flow periods was most pronounced at the Davidson Creek and Turtle Creek sites. The TDS seasonal pattern can be attributed to greater volumes of water related to snowmelt and rainfall runoff inputs to the streams. The concentration of TDS was typically higher in Turtle Creek when compared to other monitored streams that may be attributed to the beaver activity in this reach slowing the transport of water. TDS values observed in 2025 at monitored sites were similar to the observed baseline range.

1.2 MAJOR ANIONS

Overall, the 2025 concentrations of major anions (i.e., bromide, chloride, fluoride, and sulphate) were low in streams (frequently less than the DL) and did not exceed BC WQG-AL or proposed YDWL standards in any stream samples (Figures A7-8 to A7-11).

Bromide concentrations were less than the DL in all monitored streams and years (Figure A7-8).

Chloride concentrations were typically less than the DL during baseline years and have remained low but have increased since Year 1 of Construction and in 2025 were greater than the DL (0.5 mg/L) in all samples from Davidson Creek sites (DC-05, DC-10, DC-15) except for one in DC-20 (June) and

more than half the samples from Creek 661 sites 661-04 and 661-10 (Figure A7-9). Turtle Creek sites were typically less than the DL and Chedakuz Creek sites upstream of CC-10 were less than DL and sites CC-15, CC-20, CC-30, and CC-40 had 25% to 50% detectable concentrations in 2025. However, chloride concentrations have remained low compared to the WQG-AL in the monitored sites and generally less than five time the DL, with a maximum of 2.62 mg/L at 661-05 in September 2023 and a 2025 maximum of 1.93 mg/L at DC-05 and DC-10 in September. There was also a higher percentage of samples with detectable concentrations of chloride at the regional control sites 705-05 and 705-10 in 2025. Chloride concentrations were higher during the construction period in Davidson Creek, Creek 661, and Chedakuz Creek sites and have decreased slightly but remain elevated when compared to the concentrations measured during baseline and at the control sites.

Fluoride concentrations were seasonally variable with lowest concentrations observed at freshet and were lowest at the regional control sites and highest at the Turtle Creek and Chedakuz Creek sites (Figure A7-10). Fluoride concentrations were similar to baseline ranges at all sites.

The 2025 sulphate concentrations were typically below 5 mg/L at sampled sites, except at sites DC-05, DC-10, and CC-03 where monthly mean sulphate concentrations were frequently observed to be above 5 mg/L (Figure A7-11). Sulphate concentrations were also seasonally variable with greater concentrations observed in the winter months. Sulphate concentrations were greater than baseline conditions for all Davidson Creek sites (DC-05, DC-10, DC-15, and DC-20) and 661-03, 661-04, and 661-20 sites in Creek 661.

1.3 NUTRIENTS AND ORGANIC CARBON

The nitrogen species assessed in streams included total ammonia-N, nitrate-N, and nitrite-N (Figures A7-12 to A7-14). All 2025 nitrogen species concentrations were below WQG-AL and proposed YDWL standards. Total ammonia-N concentrations were generally higher and more variable through all monitoring periods at Chedakuz Creek sites compared to other sites where concentrations were typically less than 0.015 mg/L with some exceptions (Figure A7-12). Overall, total ammonia-N concentrations were similar to baseline concentrations or the range observed in control sites in 2025 except for at site 661-10 where concentrations were frequently higher than the observed baseline range.

Nitrate-N and nitrite-N concentrations were seasonally variable, with greater concentrations typically observed during low-flow/winter months (Figure A7-13 and A7-14). Nitrate-N concentrations in 2025 were similar to the baseline ranges observed except at Davidson Creek sites and sites 661-04 and 661-10 where concentrations more variable and peak concentrations observed during the high flow and in the late fall/early winter months when compared to baseline (Figures A7-13a to A7-13e). Nitrite-N concentrations were typically less than the DL (0.001 mg/L), or similar to the baseline ranges, at all sites in 2025 except for more detectable concentrations in DC-05, DC-10, and 661-10 in 2025 (Figure A7-14). However, mean nitrite-N concentrations for the detectable nitrite-N samples in 2025 at sites DC-05, DC-10, and 661-10 remained low (less than 2.2 times the DL).

Total phosphorus concentrations varied by site and season (Figure A7-15). Sites fell within the oligotrophic to meso-eutrophic range (0.02 to 0.035 mg/L), except for site 661-05 which was eutrophic (0.035 to 0.1 mg/L) and 661-10 which was predominately meso-eutrophic to eutrophic

(0.02 to 0.1 mg/L) in 2025. Total phosphorus concentrations generally increased at all sites and peaked sometime between March and June, temporarily increasing one to two trophic ranges at some sites. Total phosphorus concentrations were greater than the baseline years in Davidson Creek sites, particularly DC-05 and DC-10, and were also slightly greater than the baseline years in regional control site 705-05 in 2025. Ortho-phosphorus concentration trends were similar to total phosphorus that they varied by site, with site 661-05 having relatively higher concentrations (greater than 0.02 mg/L) than observed at the other sites, and had seasonal variability but were similar to the baseline years at all sites (Figure A7-16).

Similar to total phosphorus, organic carbon concentrations (total [TOC] and dissolved [DOC]) generally varied by site in each watershed and had seasonal variability with peak concentrations observed in the spring at freshet (Figure A7-17 and A7-18). Organic carbon was predominantly observed as DOC. The TOC concentrations were marginally lower than baseline years at most sites in Davidson and Chedakuz creeks (Figure A7-17).

1.4 CYANIDES

Observed total and weak acid dissociable (WAD) cyanide and thiocyanate concentrations during Operations in 2025 were similar to baseline concentrations at all sites (Figures A7-19 to A7-21). Monthly mean total and WAD cyanide and thiocyanate concentrations were typically less than DL at all stream sites in 2025 and during baseline. In 2025, for sites with detectable concentrations of thiocyanate mean monthly concentrations were low (0.6 to 2.9 times the DL) and observed infrequently at impact and control sites. Detections were predominately measured in March (DC-05, DC-10, DC-15, and 661-05), April (DC-15, 661-03, 661-20, CC-15, 705-10, and 705-05), and May (661-03, TC-05, TC-10, DC-05, and 705-10) as well as one observation in January (DC-05) and November (661-04).

The 2025 concentrations of WAD cyanide were below the analytical DL (0.005 mg/L) and therefore less than the WQG-AL.

1.5 TOTAL AND DISSOLVED METALS

For most metals, dissolved concentrations constituted a substantial proportion of the total concentration, indicating that metals were frequently in dissolved rather than particulate form (Figures A7-22 to A7-69). This is to be expected due to the low concentrations of TSS in streams and high TDS concentrations. Therefore, metal concentrations followed a similar temporal pattern to that observed for TDS (Figures A7-5, A7-7, and A7-46 to A7-69). The main exception was aluminum, where both total aluminum concentrations were elevated across all sites, a substantial proportion of aluminum was in the particulate form and aluminum therefore typically followed the same pattern as TSS (Figure A7-22 and A7-5). Copper, iron, and lead concentrations also tended to follow a similar seasonal pattern to that observed for TSS (i.e., tend to be particulate form; Figures A7-31 to A7-33 and A7-5).

Metals in monitored catchments may stem from natural sources (e.g., weathering of soil and rock, atmospheric precipitation/fallout, forest fires, etc.) as well as anthropogenic sources (e.g., mine construction and operation activities, forest harvesting activities, road/trail networks, etc.).

Geochemical and biological processes may also be the source for annual variability in metal concentrations. For example, magnesium, potassium, and sodium can be considered conservative and undergo relatively minor changes from natural geochemical and biological processes whereas calcium can be more reactive and are strongly influenced by geochemical and biological processes. Alternatively, metals including iron, silicon, and sulphur can be greatly influenced by microbial activity.

Geographical influences have been observed in the distribution of total and dissolved metal guideline exceedances; consequently, individual watersheds are discussed independently in the following sections.

1.5.1 DAVIDSON CREEK WATERSHED

Davidson Creek is a small headwater stream directly downgradient of construction and operation activities.

In 2025, WQG-AL guidelines were exceeded for total aluminum, total cadmium, dissolved cobalt, total and dissolved iron, and dissolved zinc (Section 2.3.4 of the main report).

Consistent with baseline concentrations, total and dissolved aluminum and total iron concentrations were elevated throughout Davidson Creek compared to the observed concentrations of other metals (Figures A7-22 to A7-69). Total aluminum, arsenic, cadmium, copper, iron, and lead followed a similar temporal pattern to TSS where concentrations were typically higher at freshet and during high streamflow periods (Figure A7-5), where other metals were dominated by the dissolved fraction and typically were higher in winter months. Mean monthly concentrations were greater than concentrations observed during baseline years at Davidson Creek sites to varying spatial and temporal extents, for the majority of metal parameters, with the exception of boron, lithium, molybdenum, and selenium in 2025. For most parameters relatively elevated concentrations in 2025 compared to baseline were observed at sites DC-05 and DC-10. Total and dissolved uranium (Figure A7-43 and A7-67) and zinc (Figure A7-45 and A7-69) were elevated downstream to site DC-15. Total and dissolved barium (Figure A7-25 and A7-49), cobalt (Figure A7-30 and A7-54), and total lead (Figure A7-33) were elevated downstream to site DC-20. Greater concentrations were observed at DC-20 but not upstream s for dissolved iron (Figure A7-56) and manganese (Figure A7-59). For some parameters, concentrations were relatively elevated in the Construction monitoring years (2023 and 2024) but had comparatively decreased in 2025 and were more similar to baseline concentrations. This included total nickel (Figure A7-38), thallium (Figure A7-42), beryllium (Figure A7-26), iron (Figure A7-32) and manganese (Figure A7-35) at site DC-15; and total and dissolved vanadium (Figure A7-44 and A7-68) at sites DC-15 and DC-20.

Many higher metal concentrations observed at freshet and rainfall events (aligned with TSS) where runoff from wildfire impacted land was a contributor to observed stream metal concentrations, however temporal increases in parameters observed in 2025 were associated with mine-related activities such as the March 2025 TSS laden water release, May and June 2025 clearing activities, and diversions from the non-contact water during Q1 and unrecovered seepage form the TSF-C in Q3 and Q4; see Section 2.3.1 in the main report for more details.

Metals that have remained consistent with baseline concentrations (i.e., less than the DL or within the observed range) through time include: total boron (Figure A7-27) and lithium (Figure A7-34) and dissolved antimony (Figure A7-47), beryllium (Figure A7-50), boron (Figure A7-51), chromium (Figure A7-53), lithium (Figure A7-58), mercury (Figure A7-60), molybdenum (Figure A7-61), nickel (Figure A7-62), and selenium (Figure A7-63).

1.5.2 CREEK 661 WATERSHED

Creek 661 runs south of the footprint of the mine and a tributary of Creek 661 is located within the footprint of mining facilities, including a portion of the proposed Open Pit and potentially may receive seepage from the TSF.

In 2025, WQG-AL were exceeded for total aluminum, total and dissolved iron, and dissolved zinc at one or more Creek 661 sites throughout the year (Section 2.3.4 in the main report).

Many of the total metal concentrations in Creek 661 were higher in the construction period and 2025 when compared to baseline. Total metal concentrations that were higher than baseline in Creek 661 sites included: total aluminum (Figure A7-22), antimony (Figure A7-23), arsenic (Figure A7-24), barium (Figure A7-25), beryllium (Figure A7-26), cadmium (Figure A7-28), chromium (Figure A7-29), cobalt (Figure A7-30), copper (Figure A7-31), iron (Figure A7-32), lead (Figure A7-33), manganese (Figure A7-35), nickel (Figure A7-38), selenium (A7-39), silver (Figure A7-40), vanadium (Figure A7-44), and zinc (Figure A7-45). Higher concentrations were predominately observed at sites 661-04, 661-05, and 661-10 though total aluminum, beryllium, cadmium, copper, iron, manganese, mercury, and vanadium concentrations were higher at sites 661-01 and/or 661-03 during the spring/freshet period compared to the previous monitoring years. Baseline data collection was initiated in July 2022 for sites 661-01, 661-03, and 661-04 and thus there is uncertainty for this visual analysis of trends.

Dissolved metal concentrations were typically similar to baseline concentrations except for: detectable concentrations of antimony (Figure A7-47) as sites 661-04 and 661-10 (Figure A7-47); uranium and vanadium in Q1 at site 661-05 (Figure A7-67 and A7-68); zinc at sites 661-04, 661-05, and 661-10 (Figure A7-69); and arsenic (Figure A7-48), cadmium (Figure A7-52), cobalt (Figure A7-54), copper (Figure A7-55), iron (Figure A7-56), manganese (Figure A7-59), nickel (Figure A7-62), selenium (Figure A7-63) at site 661-10. Baseline monitoring for dissolved metals at sites 661-01, 661-03, and 661-04 initiated in August 2022 therefore baseline freshet and high streamflow concentrations are not available; however, relative to the trends in other sites and available (2023 and 2024) data dissolved metal concentrations were relatively high for dissolved aluminum at sites 661-01, 661-03, and 661-04 (Figure A7-46); dissolved iron at site 661-01 and 661-03(Figure A7-56); dissolved manganese at site 661-03 (Figure A7-60); and dissolved silver at sites 661-03 and 661-04 (Figure A7-64).

Overall, all parameter concentrations in 2025 were lower when compared to the Construction period (2023 and 2024) and similar to baseline at Creek 661 sites with few exceptions for 661-10 (e.g., total and dissolved manganese; Figure A7-35 and A7-59). Higher metal concentrations in Creek 661 sites may partly be attributed to the wildfire activity that occurred in the watershed, particularly those that align with greater concentrations of TSS beginning with the 2025 snowmelt in late March and freshet conditions. Mine-related contributors to higher metal concentrations in Creek 661 in 2025 included ongoing construction activities which included discharge to the ground from the PS-SCP and an ore stockpile dust plume event that occurred in Q1 2025; see Section 2.3.1 of the main report for more details of Mine-related effects.

1.5.3 CHEDAKUZ CREEK WATERSHED

Chedakuz Creek is a larger watercourse and influenced by several anthropogenic sources along its length (e.g., forest harvesting activities, road/trail networks, cattle grazing).

The monthly mean concentrations exceeded the BC WQG-AL maximum for dissolved iron in the Chedakuz Creek watershed and at site CC-15, the YDWL standard for dissolved manganese was exceeded for in March, April, May, August, October, and November (see Section 2.3.4 of the main report).

Similar to the other monitored watersheds, total and dissolved aluminum concentrations followed a similar temporal pattern to TSS, unlike other metals which were dominated by the dissolved fraction (Figures A7-22 to A7-69 and A7-5). For many metals, concentrations remain low and appear similar across all sites; for others a downstream spatial gradient was observed (e.g., arsenic, barium, copper, iron, manganese). Throughout the construction and operations (since 2023), total and dissolved iron and molybdenum appear to have increased at site CC-40 (Figures A7-32, A7-56, A7-37, and A7-61). Total and dissolved uranium have also increased at site CC-40, and CC-30 to a lessor extent, however uranium concentrations have also increased at upstream sites CC-03 and CC-05 and there is no distinct spatial pattern in the Chedakuz Creek sites (Figure A7-43 and A7-67). Some metals were observed to be greater than baseline during the construction period but have generally decreased in 2025 compared to the 2024 observations (e.g., aluminum, total barium, total lead).

1.5.4 TURTLE CREEK WATERSHED

No Mine-related effects were anticipated at Turtle Creek sites as there has been no construction of the airstrip to date.

One monthly mean dissolved iron concentration at site TC-10 in September 2025 (0.443 mg/L) exceeded the BC WQG-AL maximum of 0.35 mg/L; the relatively elevated concentration did not persist (Figure A7-56). No other exceedances of the BC WQG-AL were observed for the mean monthly concentrations in 2025.

Overall, the 2025 mean monthly metal concentrations in the Turtle Creek watershed sites were similar to that observed during baseline years, baseline monitoring was initiated in July 2022 for Turtle Creek (Figures A7-22 to A7-69). Similar to the other monitored watersheds, total and dissolved aluminum concentrations followed a similar temporal pattern to TSS, unlike other metals which were dominated by the dissolved fraction. Metal concentrations were similar between sites (including the upstream control, TC-01) or slightly greater at TC-05 and TC-10 compared to sites TC-01 and TC-15 (e.g., total barium, total iron, and total manganese (Figures A7-25, A7-32, and A7-35). One exception to this trend was total arsenic, where concentrations were highest at TC-01 when compared to all other sites (Figure A7-22).

1.5.5 REGIONAL CONTROL SITES

In 2025, the total and dissolved iron BC WQG-AL maximum was exceeded at site 705-05 for August, September, and October monthly means.

The 2025 mean monthly metal concentrations and seasonal trends at the regional control sites, 705-05 and 705-10 on Creek 705 and FC-01 on Fawnie Creek tributary, have typically been consistent through time (Figures A7-22 to A7-69). One exception is total and dissolved manganese at site 705-05 which appears to have increased in 2025 compared to the baseline and construction monitoring periods (Figure A7-35 and A7-59). Similar to the other monitored watersheds, total and dissolved aluminum concentrations followed a similar temporal pattern to TSS, unlike other metals which were dominated by the dissolved fraction. Concentrations of metals at regional control sites were similar across sites or higher in Creek 705 than at FC-01, with the exception of total and dissolved arsenic, cadmium, and vanadium which were typically higher in FC-01. Concentrations of metals at regional control sites were lower or similar to concentrations observed at monitored impact sites in Davidson Creek, Creek 661, and Chedakuz Creek, and low compared to WQG-ALs.

2. LAKE SURFACE WATER QUALITY

Kuyakuz Lake (KL-01) and Tatelkuz Lake (TL-01, TL-02, TL-03, and TL-04) are monitored quarterly. Tatelkuz Lake is located downstream of Creek 661 which will receive unrecovered seepage from the Plant Site or Camp Site and unrecovered seepage from the TSF. The lake is monitored at TL-01, represented the lake water quality, and at three littoral zone locations at the edge of the lake (TL-02, TL-03, and TL-04; Figure 1.7-2 of the main report). Kuyakuz Lake is upstream of the Mine footprint and KL-01 represents the control site for Tatelkuz Lake. No Mine-related effects were expected at lake sites in 2025 because of the observed extent of Mine-related changes in the streams (see Section 2.3 of the main report) and the downstream distance of the lakes from construction and operation activities.

Timeseries graphs for monthly means of parameter concentrations by depth layer are provided in Appendix A-9. Depth layers presented included:

- Epilimnion/Littoral: the surface layer of the lake or within the littoral zone of Tatelkuz Lake (TL-02, TL-03, and TL-04);
- Metalimnion: the middle layer of the lake; and
- Hypolimnion: the bottom of the lake.

Monthly mean timeseries of lake physical field parameters profiles are provided in Appendix A-10. Profiles measured throughout the water column at Kuyakuz Lake and Tatelkuz Lake sites KL-01 and TL-01 are provided in Figures A10-1 to A10-6. Littoral measurements measured at Tatelkuz Lake sites TL-02, TL-03, and TL-04 are provided in Figures A10-7 to A10-12.

2.1 FIELD PARAMETERS

Lake field measurement profiles in 2025 were similar to profiles measured during baseline monitoring, with the following exceptions (Appendix A-10). The pH profiles in both Tatelkuz and Kuyakuz lakes were greater in the epilimnion when compared to baseline years. However, at all depths and years the pH was within the BC WQG-AL range (i.e., between 6.5 and 9 pH units). The open water profiles in for dissolved oxygen tended to vary between years in Tatelkuz and Kuyakuz lakes (Figure A10-4) and likely as a result of natural variation (i.e., no consistent change). The littoral field measurements for Tatelkuz Lake (TL-02, TL-03, and TL-04) in 2025 were similar to among sites and temporally beginning in 2022 (Figures A10-7 to A10-12).

Tatelkuz Lake temperature profiles indicated the lake was fully mixed (i.e., consistent temperature throughout the water column) in the winter months (e.g., February) and were thermally stratified (i.e., warmer surface waters and rapid decline to colder bottom waters) in the spring, summer, and fall (e.g., between May and October; Figure A10-2). The Kuyakuz Lake profiles indicated the lake typically does not stratify throughout the year, with May 2023 being an exception (Figure A10-2). Littoral temperatures in Tatelkuz Lake sites were consistent across sites and show typical season temperature trends of peak temperatures during summer months (e.g., July or August) and colder water temperatures during winter months (i.e., December through to April; Figure A10-8).

2.2 PHYSICAL PARAMATERS

Monitored lake sites in 2025 were near-neutral to slightly alkaline, with laboratory-measured pH values ranging from 6.99 (TL-01 hypolimnion, October) to 8.71 (TL-01 epilimnion, July; Figure A9-1). Inter-annual or intra-annual (seasonal) variability in laboratory-measured pH was not observed in lakes. There was no variation in pH by depth observed at Kuyakuz Lake, whereas at TL-01 the median laboratory-measured pH value decreased slightly with increasing depth (Figure A11). Field pH measured in lake profiles and at littoral sites in 2025 have a similar range of measured pH as the laboratory-measured pH (7.18 to 8.71 pH units) and indicate that pH typically decreases with depth with both lakes (Figure A10-1 and A10-7). Field and laboratory-measured pH values in 2025 for Tatelkuz Lake and Kuyakuz Lake were within the BC WQG-AL range (6.5 to 9.0).

Total alkalinity in monitored lakes was typically higher in Kuyakuz Lake, with a few exceptions where concentrations measured at littoral zone sites in Tatelkuz lake (TL-04) were greater than KL-01 (Figure A10-4). Total alkalinity in the monitored depths of both monitored lakes (epilimnion/littoral, metalimnion, and hypolimnion) had similar concentrations. Alkalinity values at all lake stations and depths have consistently been higher than 20 mg/L as $CaCO_3$ (60 and 97.5 mg/L as $CaCO_3$), indicating low sensitivity to acid inputs.

Kuyakuz and Tatelkuz lakes are both classified as moderately hard water lakes (i.e., hardness between 121 mg/L and 180 mg/L; Figure A9-5). Hardness has remained consistent at sites and depths through all monitoring periods.

Total dissolved solids were similar among lakes and depths (Figure A9-6). Seasonal variability was observed in TDS measurements where concentrations were typically higher during winter months (representing under-ice measurements) when compared to concentrations in summer and early fall.

Turbidity and TSS have typically remained low in lakes throughout monitored years (Figure A9-7 and A9-8). In 2025, turbidity values were low, ranging from 0.1 to 4.18 Nephelometric Turbidity Unit (NTU) and were within the observed baseline range for all depths (Figure A9-7). In 2025, TSS was greater than DL in the Kuyakuz Lake shallow sample in February and in all Tatelkuz Lake samples in May (Figure A9-8).

Observed TSS and turbidity values were generally low year-round. Minor seasonal variability was observed in turbidity with higher levels observed in the Fall months (September and October) in KL-01 and TL-01 but higher levels observed in the Spring (March to May) in TL-02, TL-03, and TL-04.

2.3 MAJOR ANIONS

Bromide, chloride, fluoride, and sulphate concentrations have been low and consistent in lakes samples through all monitoring periods (Figures A9-9 to A9-12). Bromide and chloride concentrations were less than the DL at all lake sites, depths, and years. Fluoride, and sulphate were low and well below the BC WQG-ALs. Sulphate concentrations have consistently been higher in Tatelkuz Lake (2.8 to 4.3 mg/L) than Kuyakuz Lake (0.5 to 3.0 mg/L).

2.4 NUTRIENTS AND ORGANIC CARBON

Nitrogen species (total ammonia-N, nitrate-N, and nitrite-N) measured in lakes were typically low in all monitoring years in Tatelkuz Lake and Kuyakuz Lake (Figures A9-13 to A9-15). Nitrogen was predominantly in its organic form as represented by Total Kjeldahl Nitrogen (Figure A9-16). All nitrogen species were below the BC WQG-AL in 2025 and throughout the monitoring period.

Total ammonia-N concentrations were detectable and greater at Kuyakuz Lake when compared to all Tatelkuz Lake depths and littoral zone sites (Figure A9-13). Concentrations of total ammonia-N in Kuyakuz Lake tend to be greatest in the hypolimnion in the summer months when compared to other months and depths. Nitrate-N concentrations were variable among lakes and depths and were higher in the winter months (Figure A9-14). Nitrate-N concentrations increased with depth in Tatelkuz lake. Nitrite-N concentrations were typically below the DL except for the winter months (Figure A9-15). Concentrations were typically higher at Kuyakuz Lake compared to Tatelkuz Lake. Some depth variation was observed, with higher concentrations occurring in the epilimnion and hypolimnion compared to the metalimnion at both lakes.

Total phosphorus concentrations were similar between the lakes with greater concentrations frequently observed in the hypolimnion (Figure A9-17). Total phosphorus concentrations ranged from mesotrophic (0.01 to 0.02 mg/L) to eutrophic (0.035 to 0.1 mg/L) in monitored lakes and have been higher than the upper BC WQG-AL range of 0.015 mg/L for most months throughout the monitoring years. Ortho-phosphorus concentrations were similar between lakes at the epilimnion and littoral depths (Figure A9-18). At the metalimnion and hypolimnion depths ortho-phosphorus concentrations were greater in Tatelkuz Lake when compared to Kuyakuz Lake. Seasonal variation for total phosphorus and ortho-phosphorus was evident with greater concentrations in the spring/summer months.

Organic carbon concentrations in lake sites were similar among years and depths (Figure A9-22 and A9-23). The majority of TOC was in the dissolved phase as DOC.

2.5 CYANIDES

Total and WAD cyanide and thiocyanate (Figures A9-19 to A9-21) concentrations in lakes were below the DL (0.005 mg/L) in all samples collected from Tatelkuz and Kuyakuz lakes in 2025 and throughout the monitoring period with the exception of a single total cyanide concentration collected at the hypolimnion in Tatelkuz Lake in 2022 (September) and a littoral thiocyanate concentration in 2025 (July).

2.6 TOTAL AND DISSOLVED METALS

Overall, total and dissolved metals were low among all lake sites, across all monitoring years, and frequently less than the DL at all depths sampled (Figures A9-24 to A9-87). The total and dissolved metals in monitored lakes in the 2025 (i.e., Operations) were within the baseline range observed for each site. Total antimony, chromium, and nickel, which have typically been less the DL through time, had detectable observations in some months in 2025; however these were considered spurious given they did not occur consistently (Figures A9-25, A9-33, and A9-42).

The range of most metal concentrations observed were similar across lake sites except for greater total and dissolved barium and magnesium concentrations in Kuyakuz Lake when compared to Tatelkuz Lake sites. In addition, Tatelkuz Lake had higher concentrations of total and dissolved arsenic, selenium, sodium, and uranium, and dissolved copper when compared to Kuyakuz Lake. Total iron, dissolved magnesium, and dissolved zinc were generally higher in the hypolimnion of Kuyakuz Lake, and total and dissolved magnesium were generally higher in the hypolimnion of both lakes.

No exceedances of metal WQG-ALs occurred at Kuyakuz or Tatelkuz lakes in 2025.

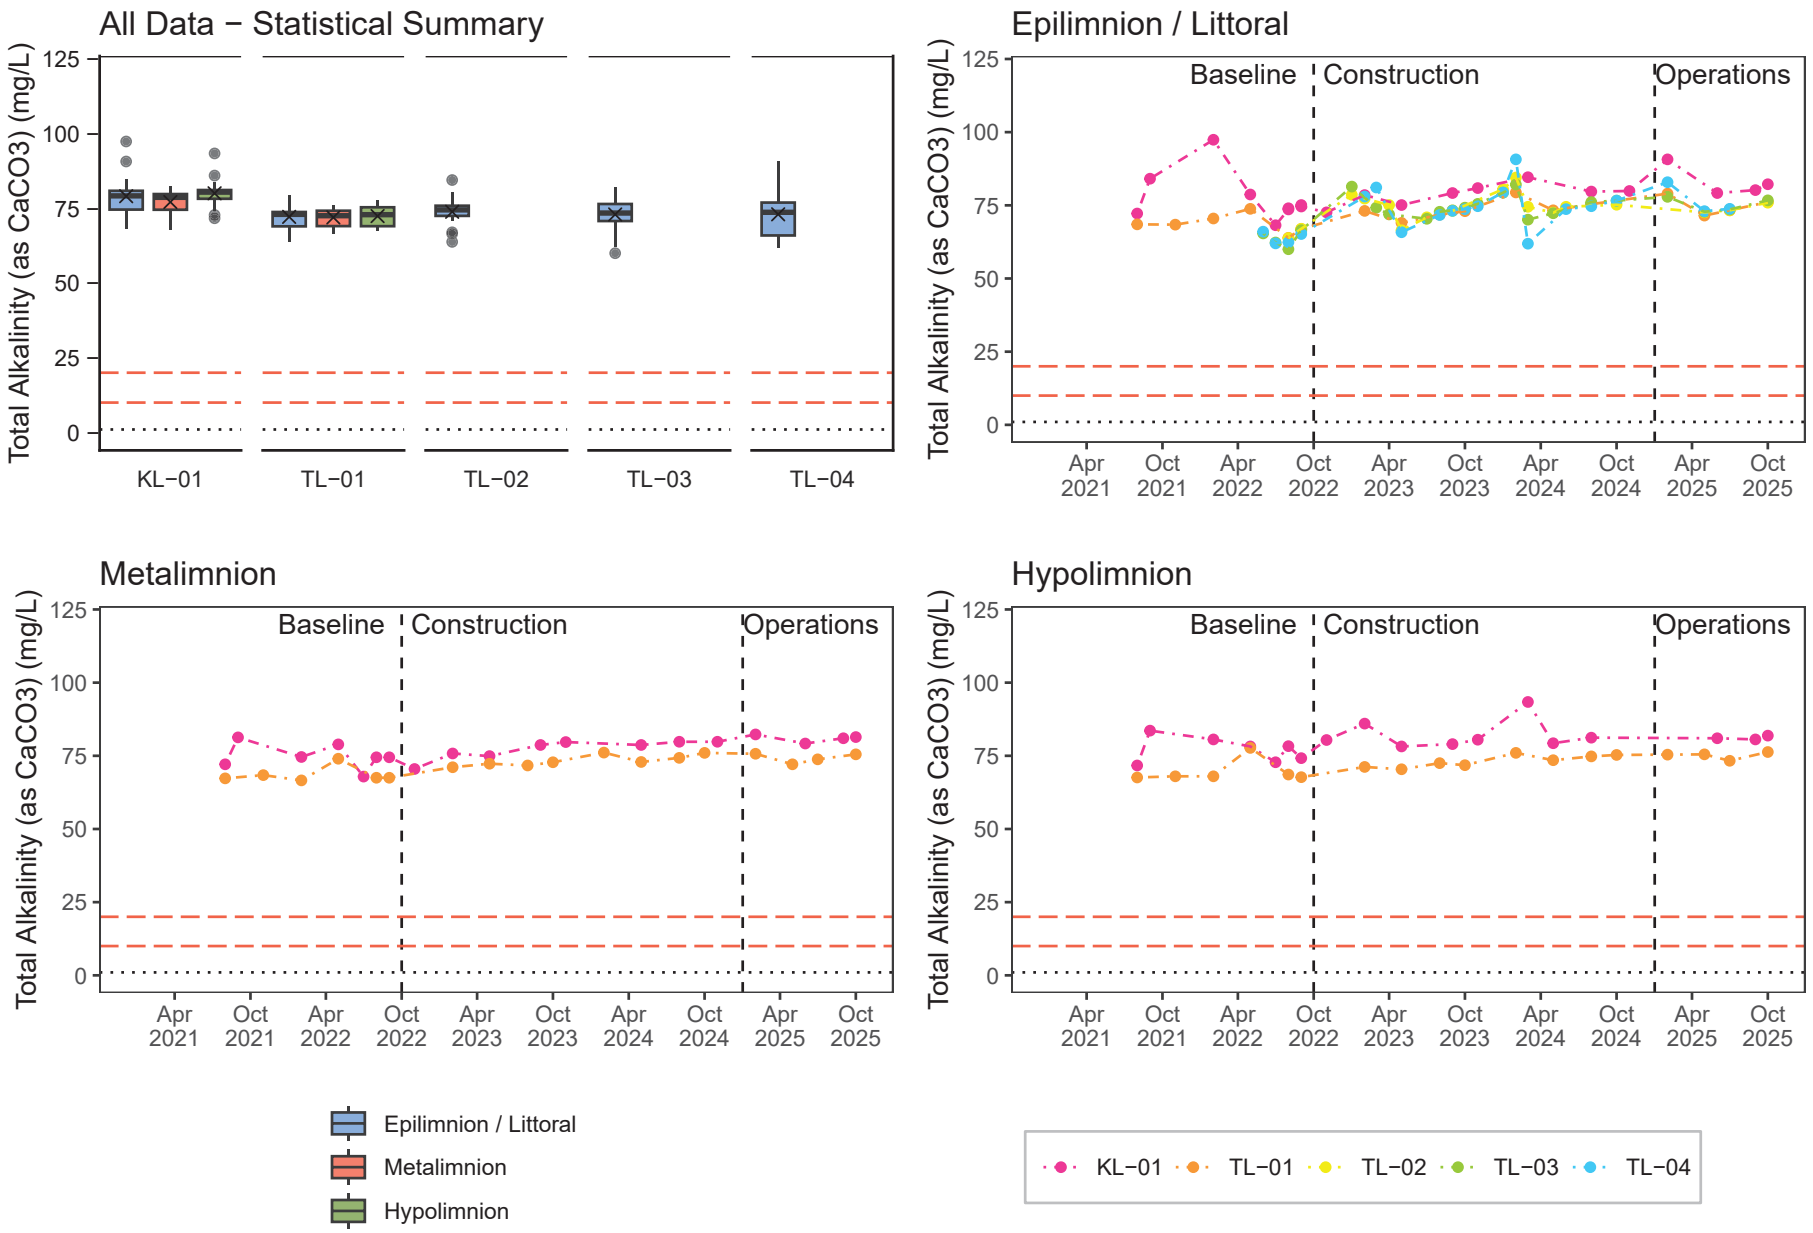
Appendix A-9 2021 to 2025 Monthly Mean Lake Water Quality Graphs

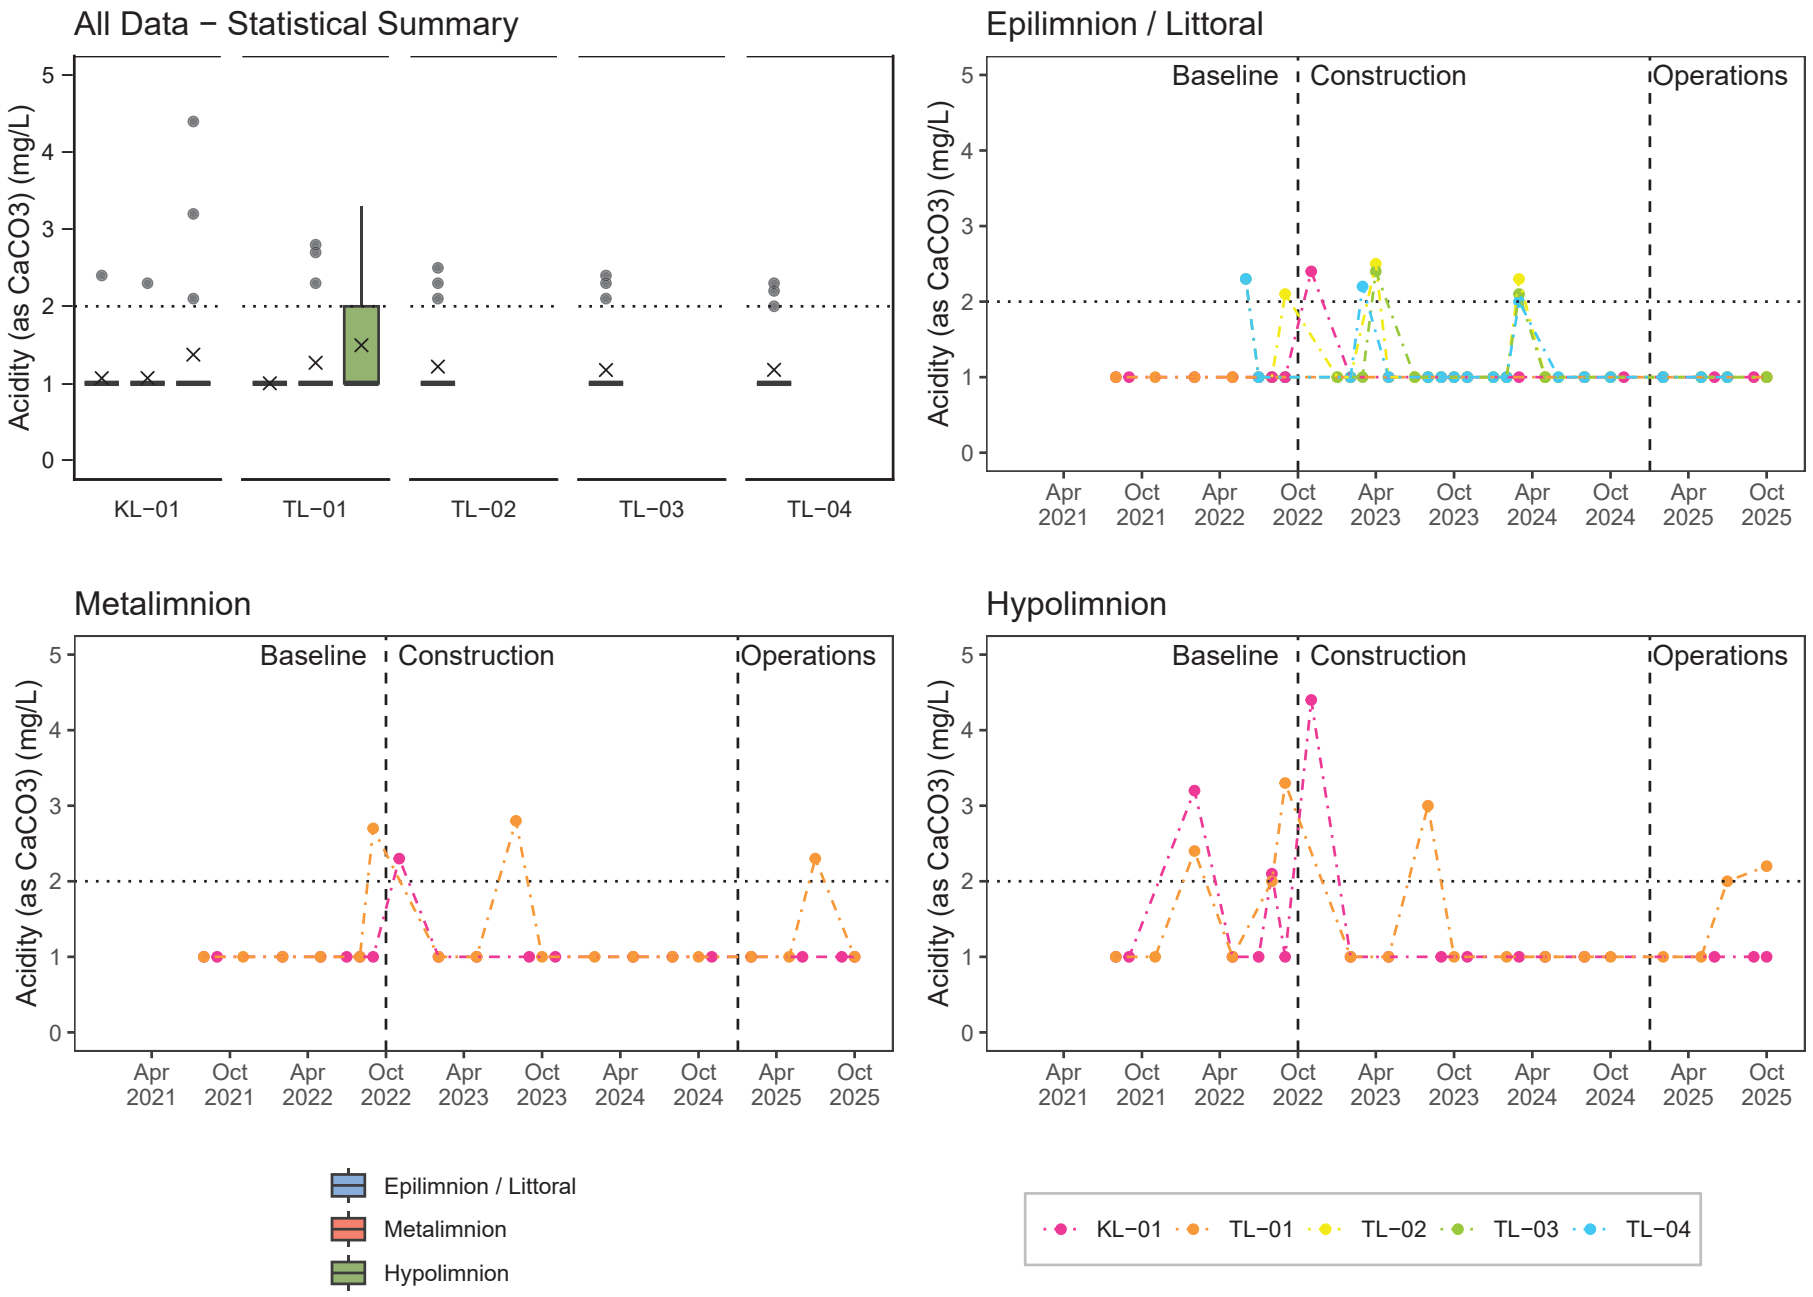
Notes: BC WQG−AL lower is 6.5.
BC WQG−AL upper is 9.0. pH values are laboratory−measured.

Figure A9−1: pH in AEMP Monitored Lakes, 2021 to 2025



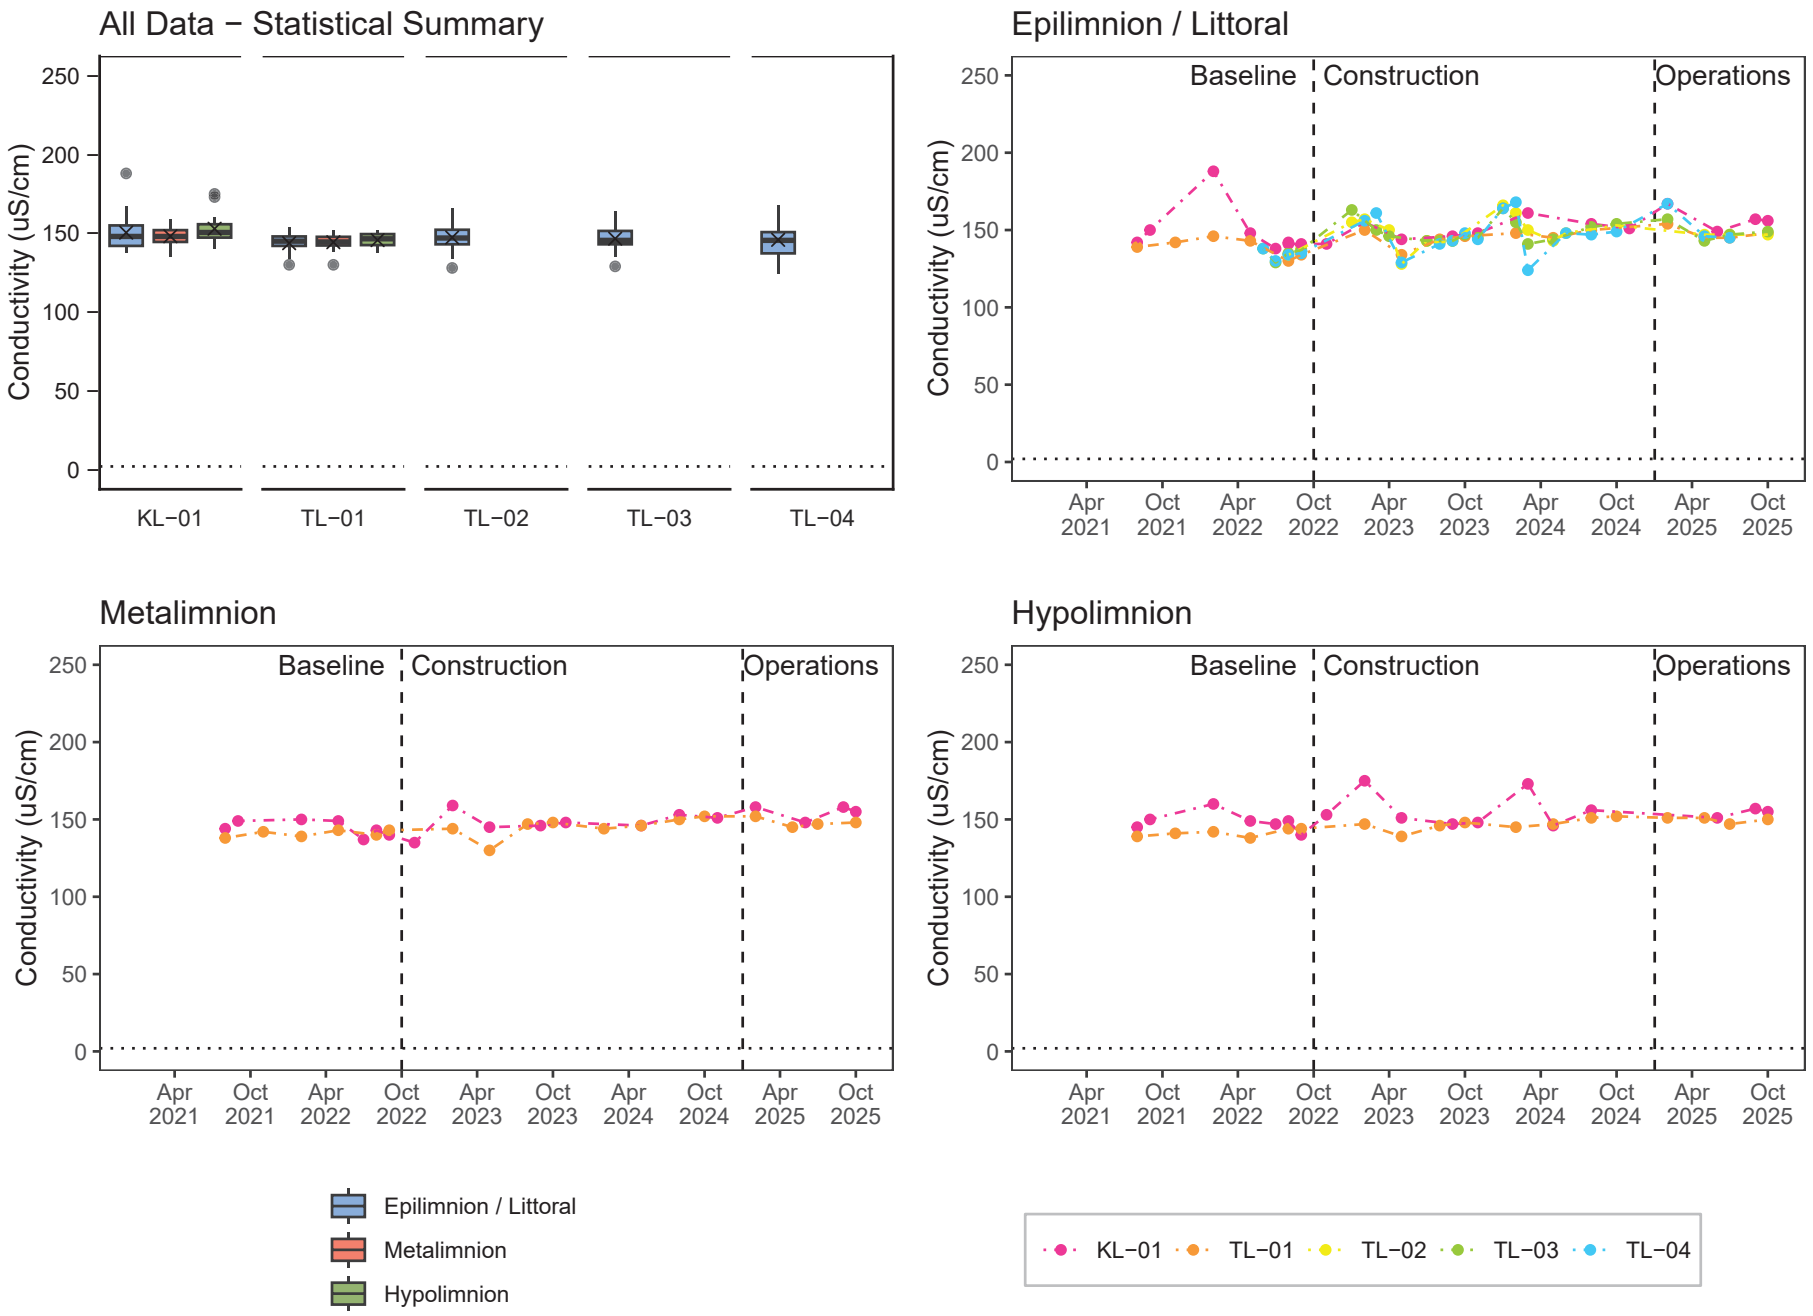
Notes: Dashed line indicates minimum detection limits.
Red dashed lines indicate BC WQG−AL working guideline ranges for sensitivity to acid inputs:
< 10 mg/L as $CaCO_3$, highly sensitive to acid inputs.
10 − 20 mg/L as $CaCO_3$, moderately sensitive to acid inputs.
> 20 mg/L as $CaCO_3$, low sensitivity to acid inputs.

Figure A9−2: Alkalinity in AEMP Monitored Lakes, 2021 to 2025



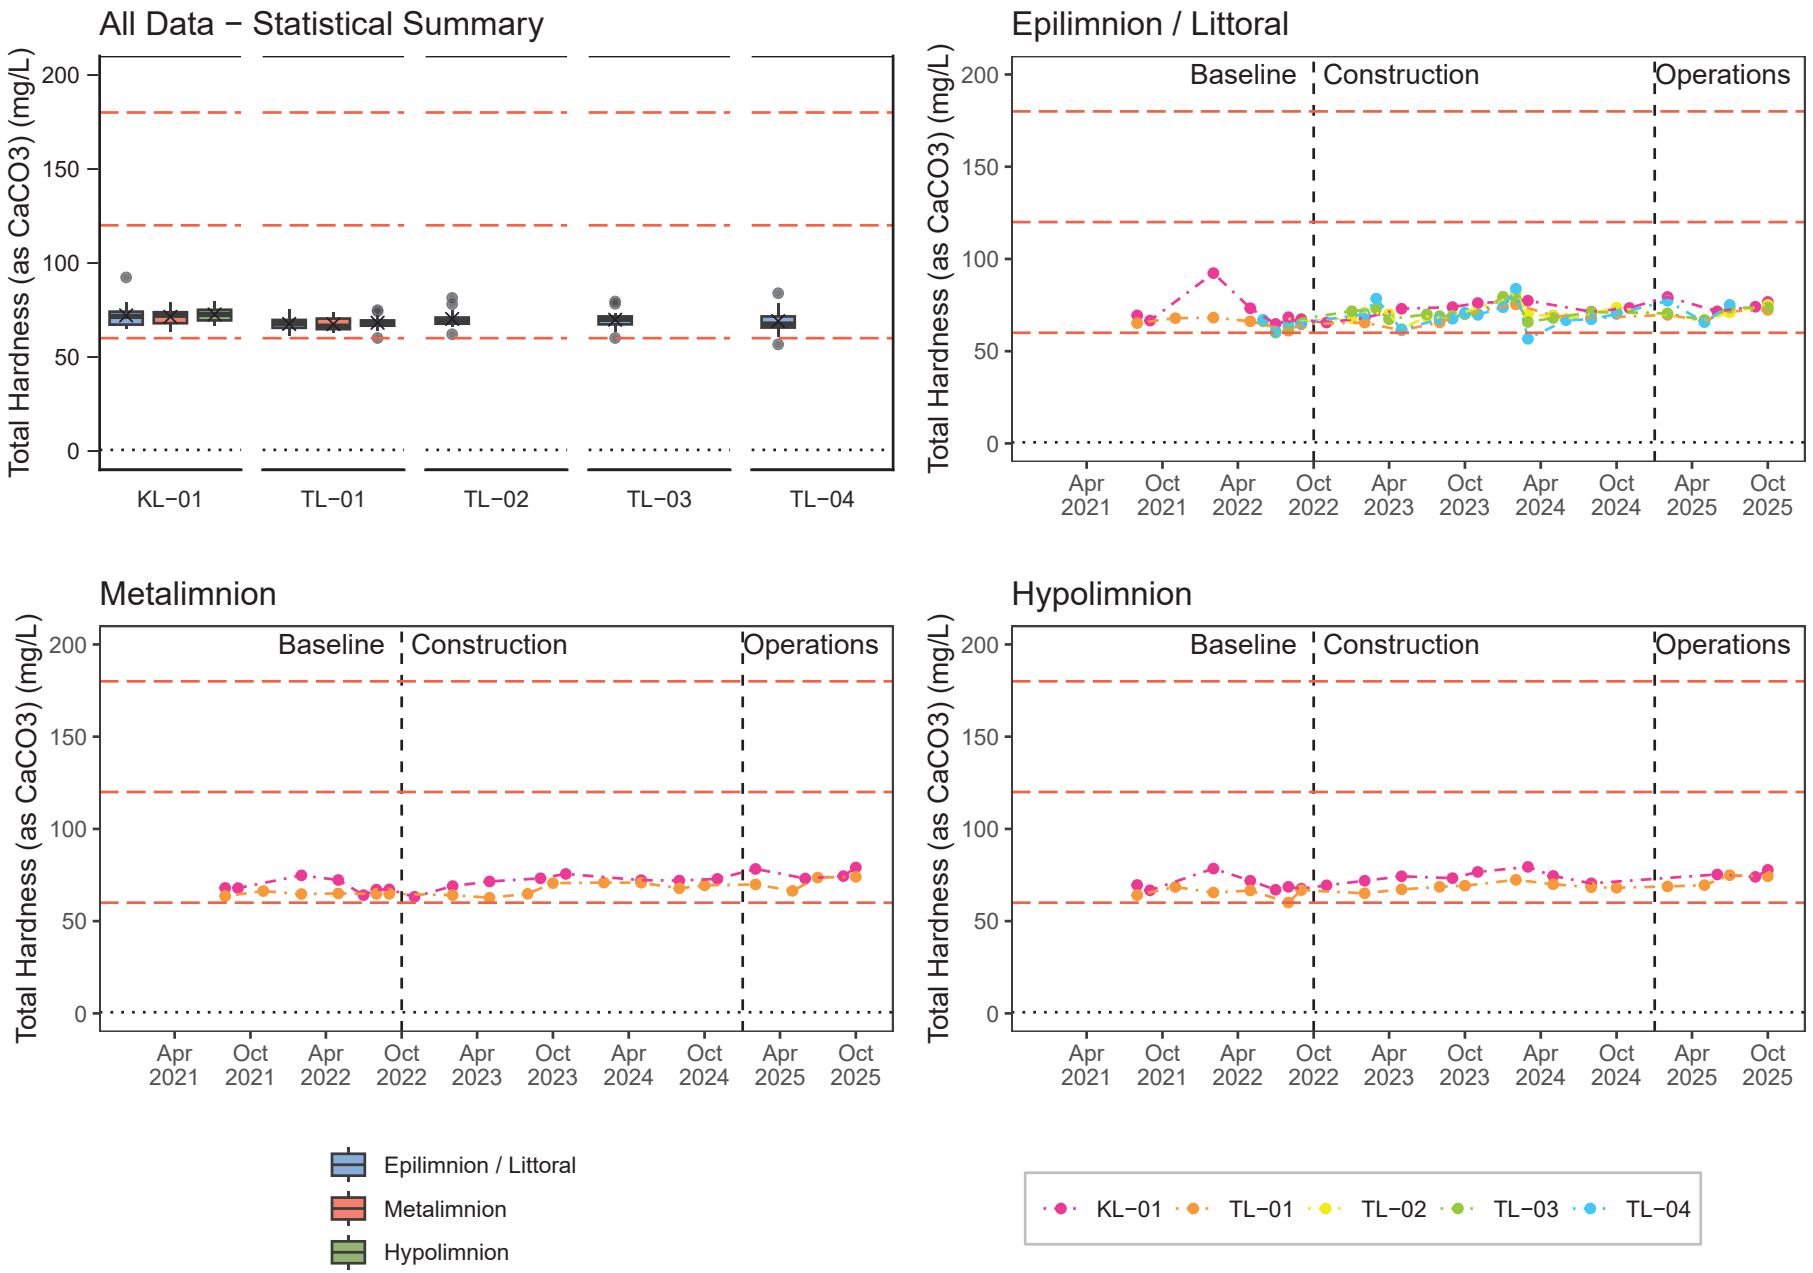
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−3: Acidity in AEMP Monitored Lakes, 2021 to 2025



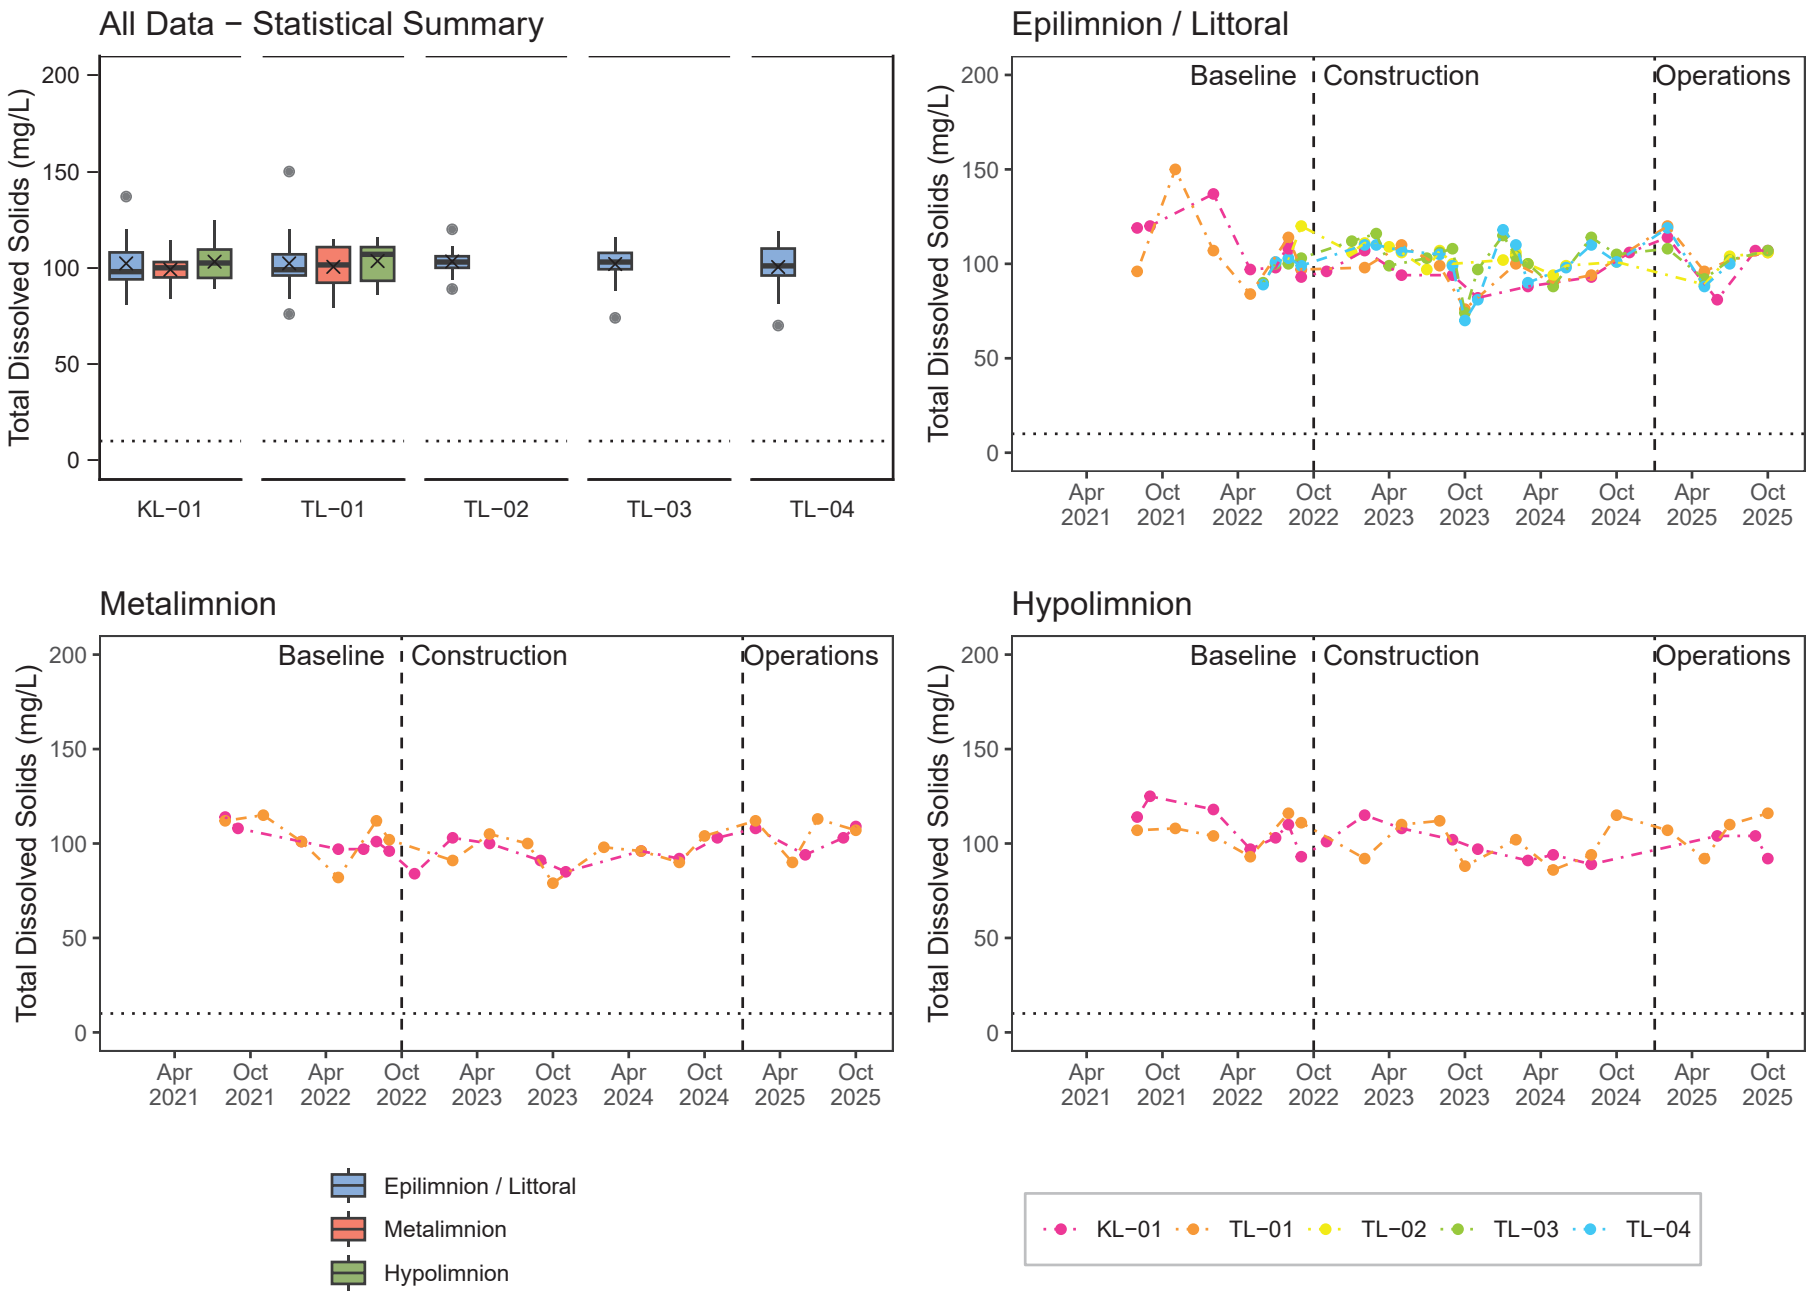
Notes: Dashed line indicates minimum detection limits.

Figure A9−4: Conductivity in AEMP Monitored Lakes, 2021 to 2025



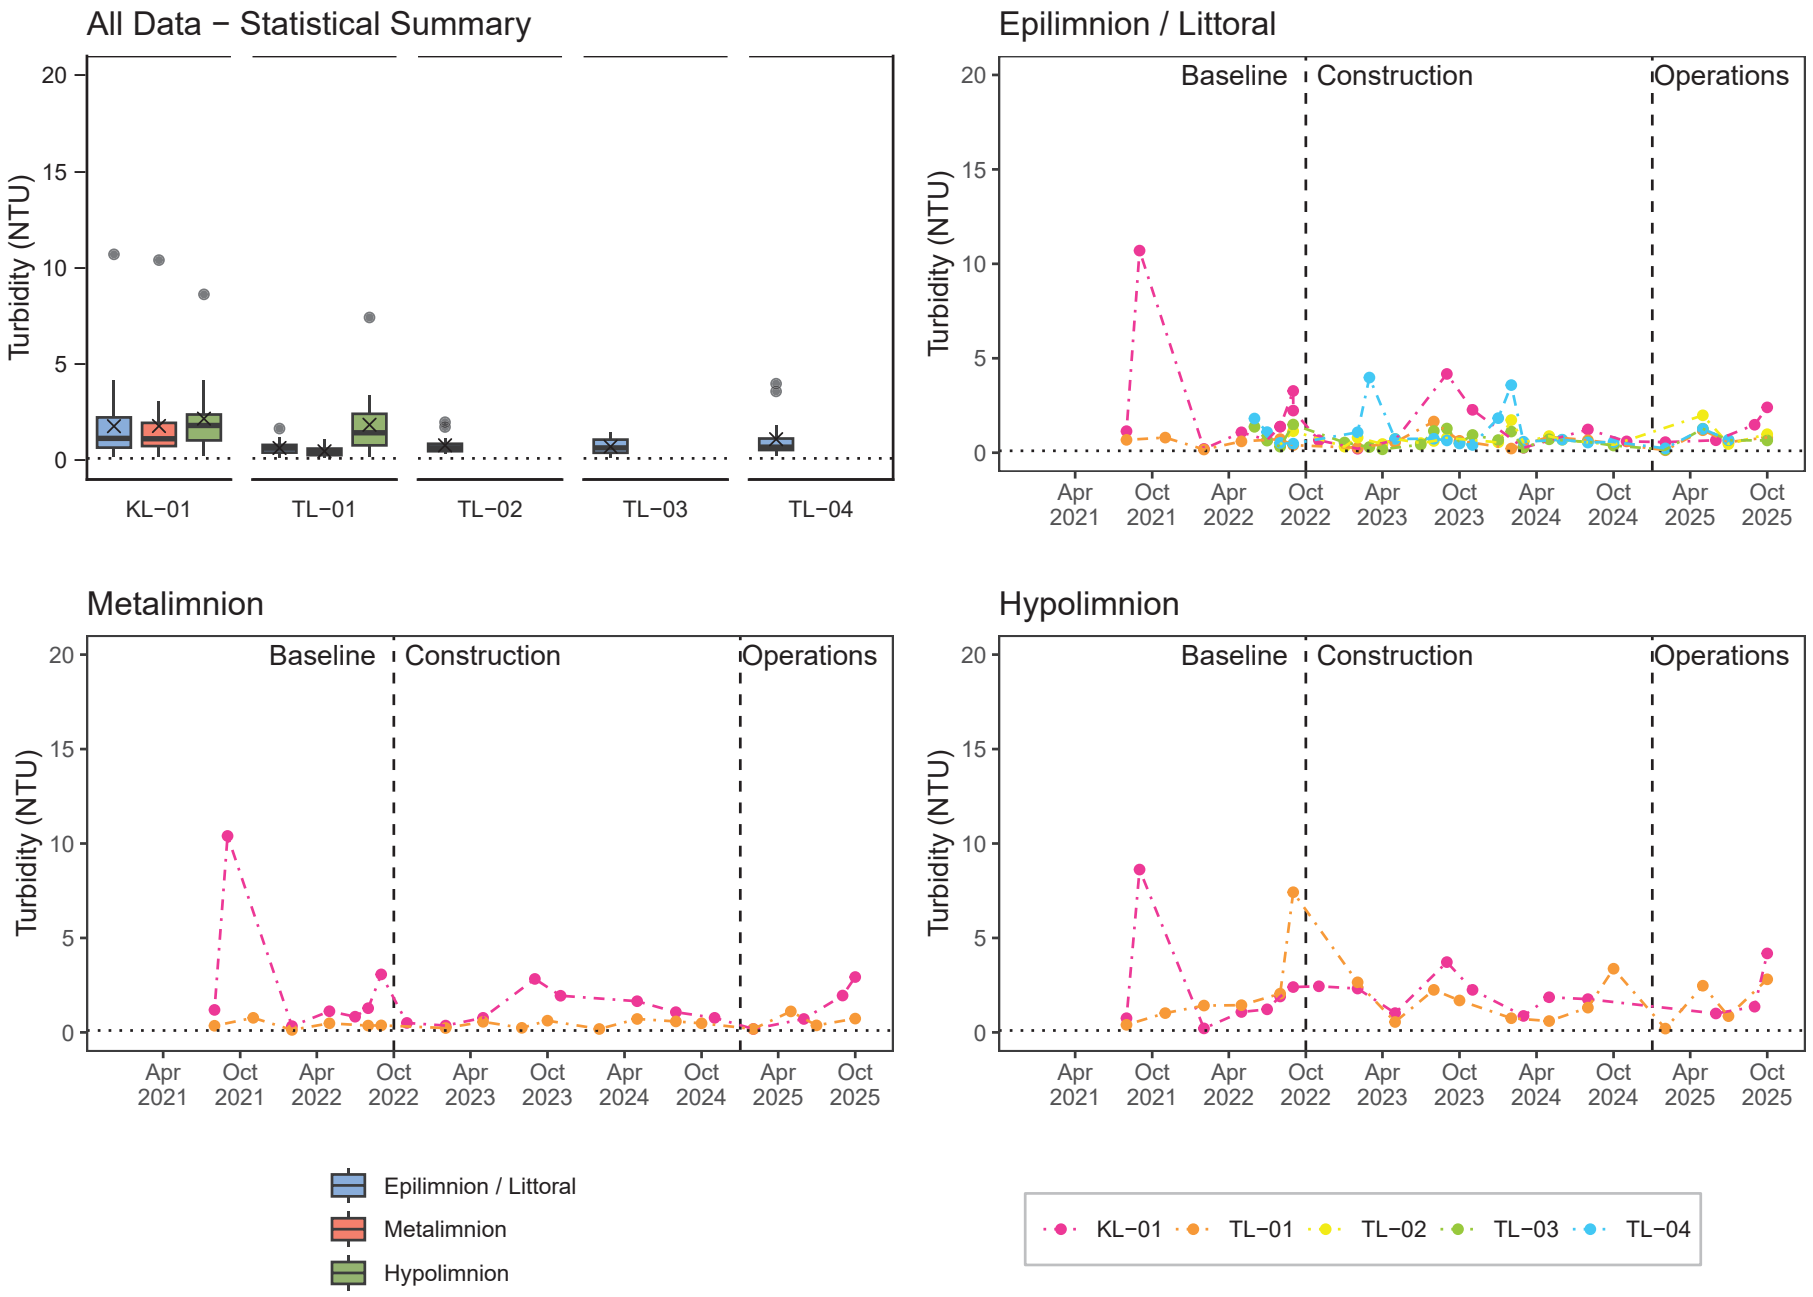
Notes: Dashed line indicates minimum detection limits.
Red dashed lines indicate classification ranges for hardness concentrations (Briggs et al. 1977):
< 60 mg/L, soft; 61 − 120 mg/L, moderately hard, 121−180 mg/L, hard; > 180 mg/L, very hard.

Figure A9−5: Hardness in AEMP Monitored Lakes, 2021 to 2025



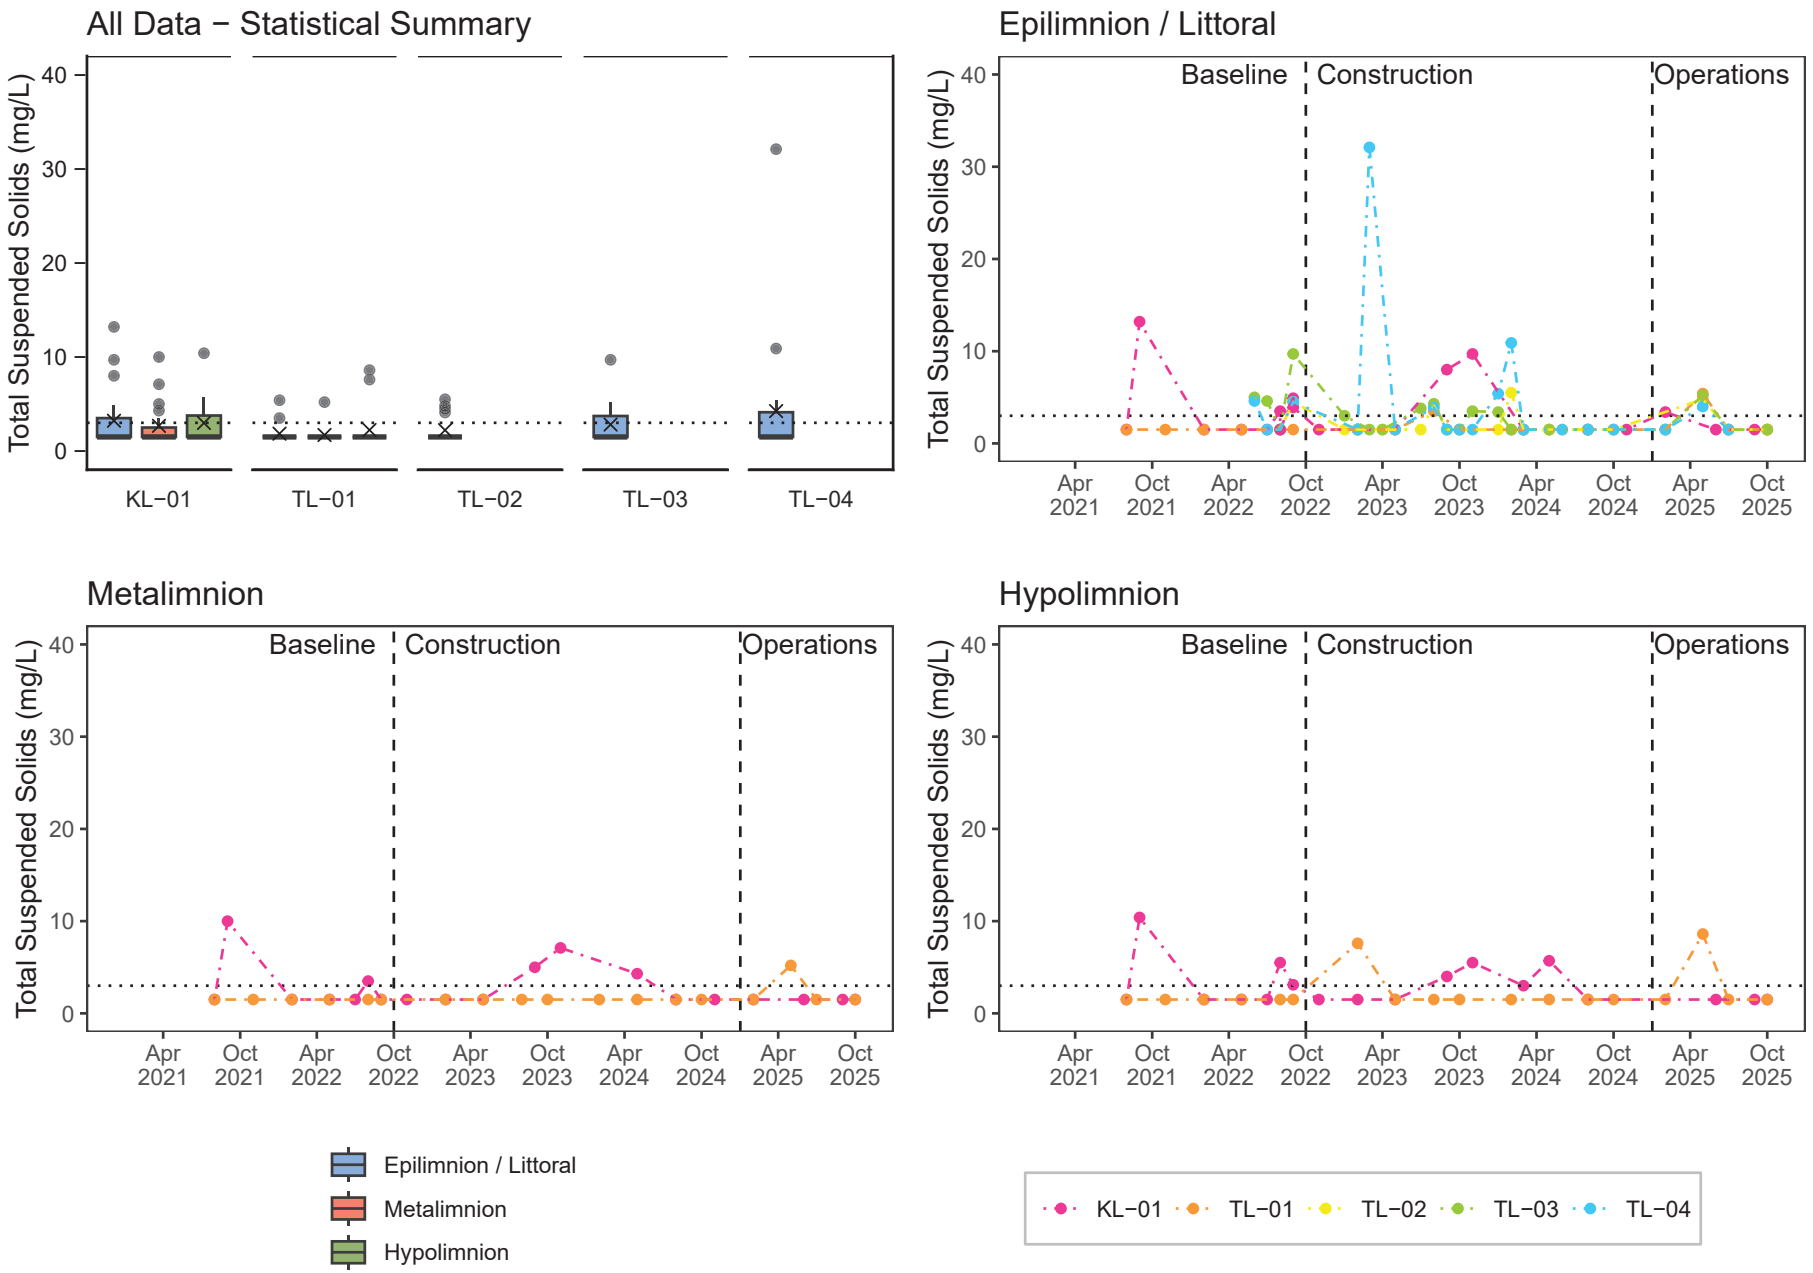
Notes: Dashed line indicates minimum detection limits.
Water quality guidelines for dissolved solids are dependent on background levels.

Figure A9−6: Total Dissolved Solids in AEMP Monitored Lakes, 2021 to 2025



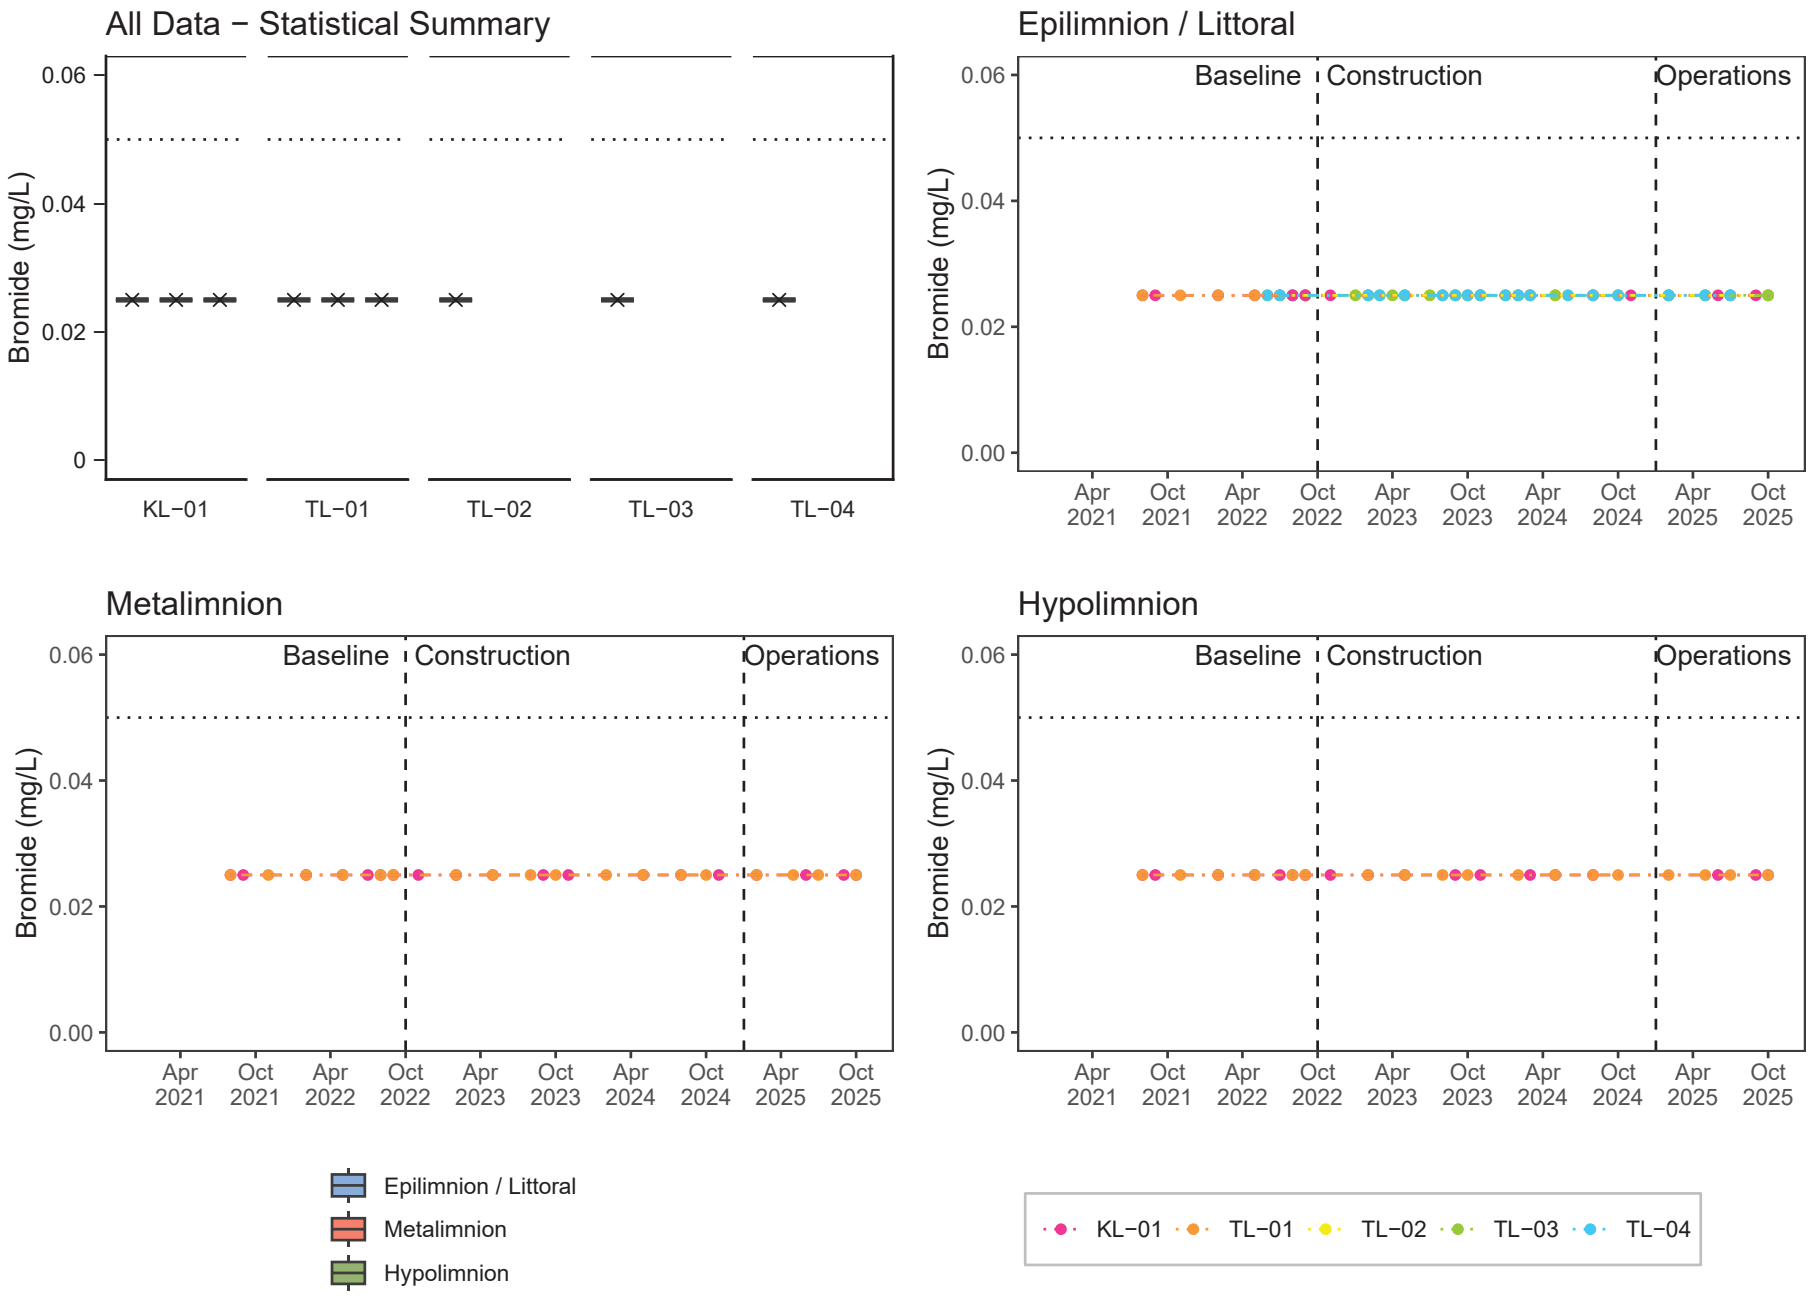
Notes: Dashed line indicates minimum detection limits.
BC WQG−AL is specific to site baseline conditions.

Figure A9−7: Turbidity in AEMP Monitored Lakes, 2021 to 2025



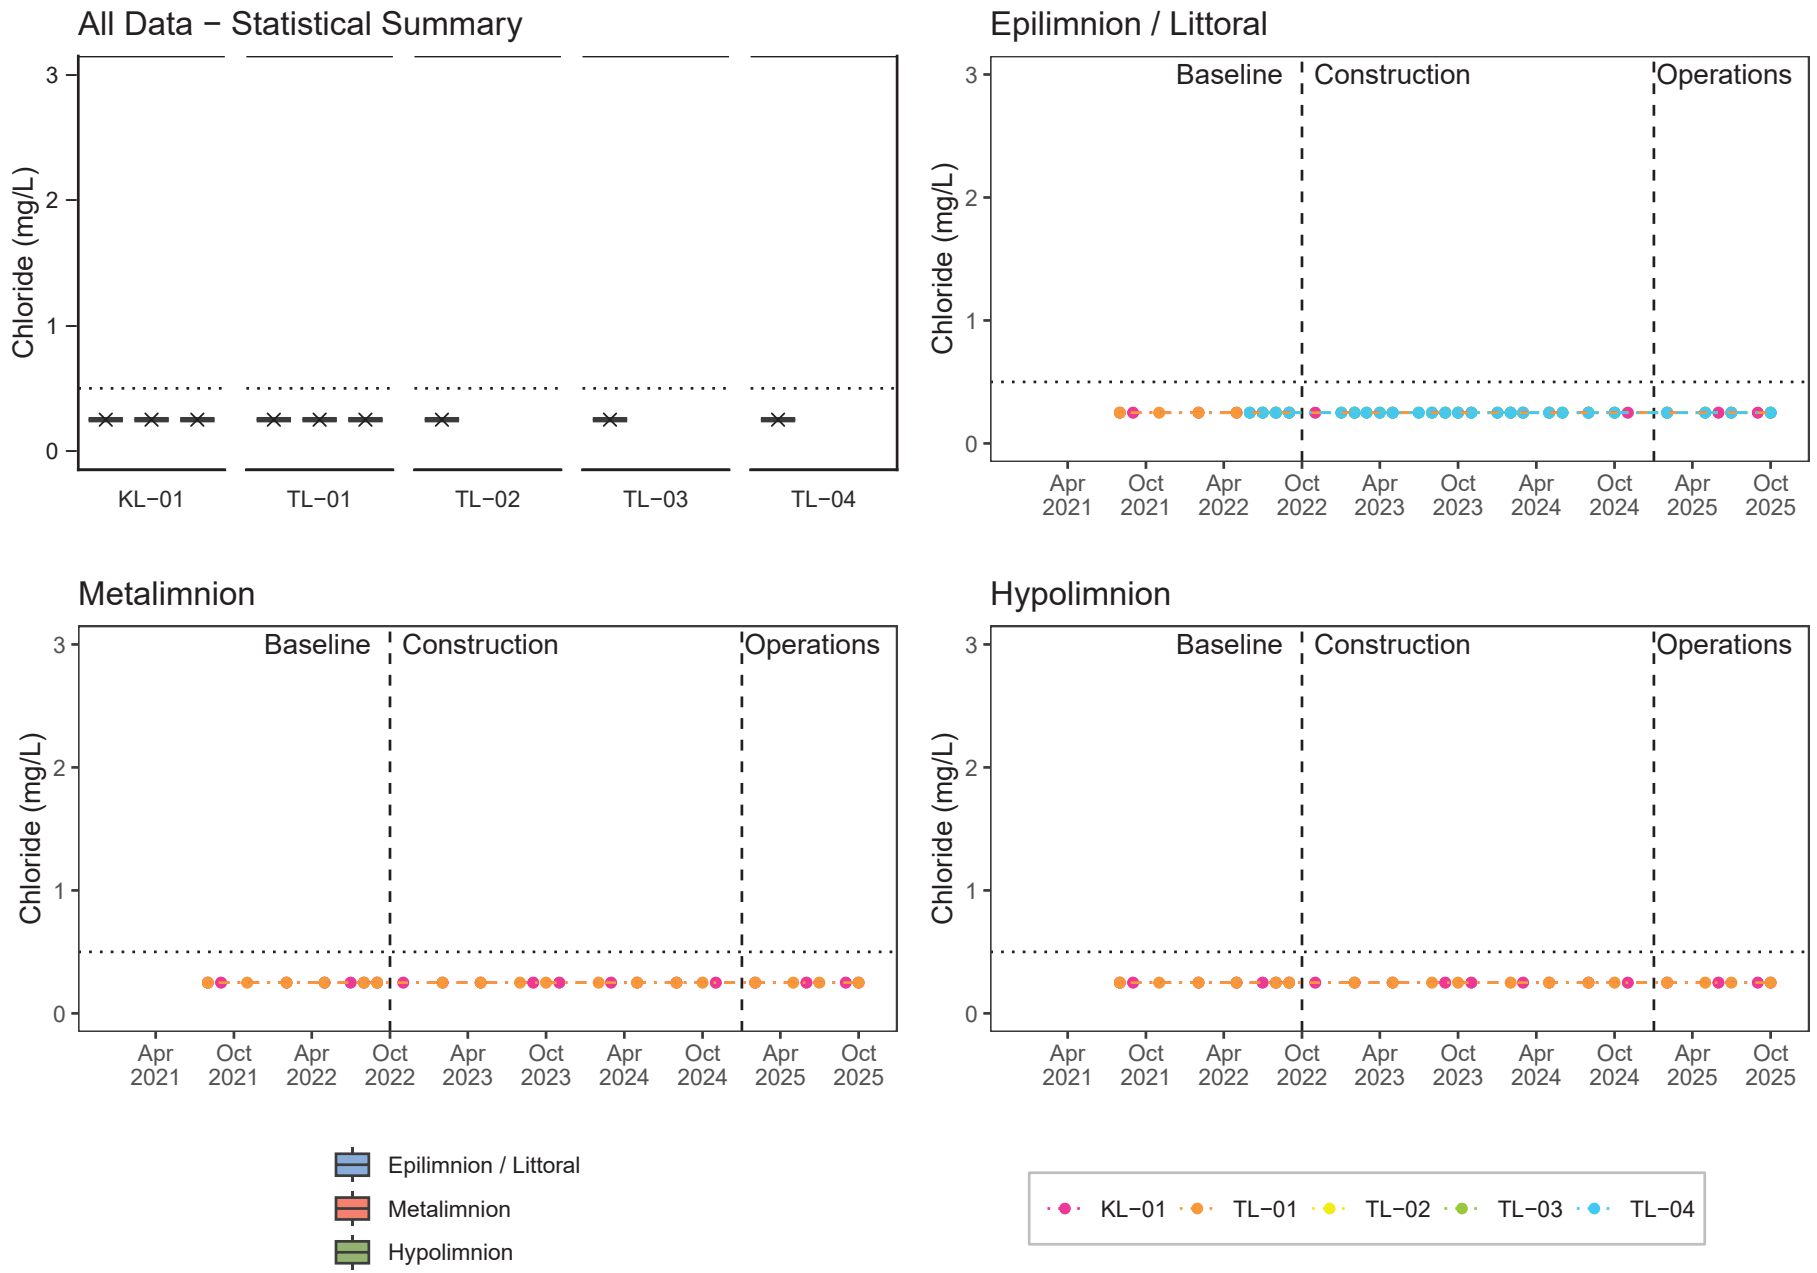
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.
Water quality guidelines for suspended solids are dependent on background levels.

Figure A9−8: Total Suspended Solids in AEMP Monitored Lakes, 2021 to 2025



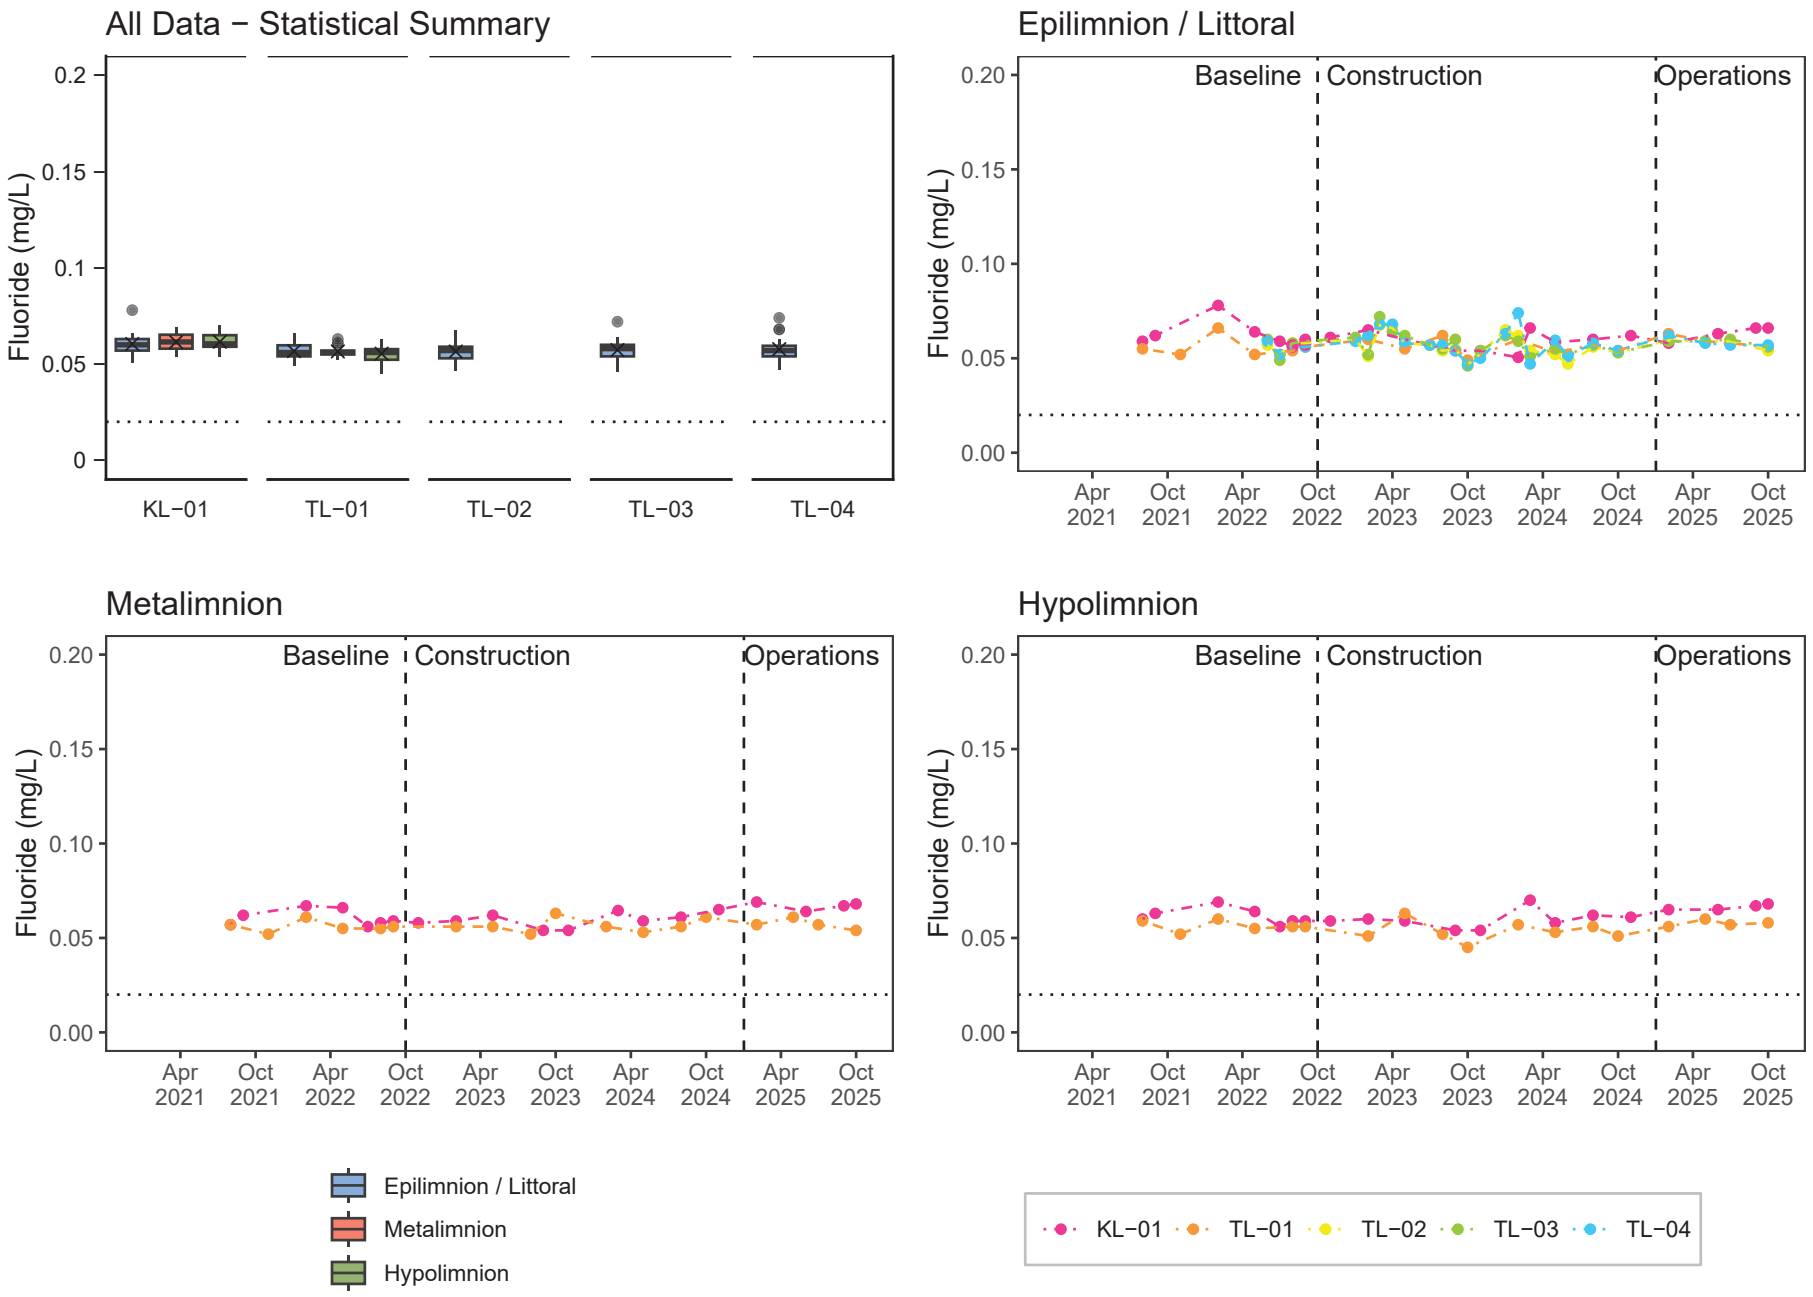
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−9: Bromide in AEMP Monitored Lakes, 2021 to 2025



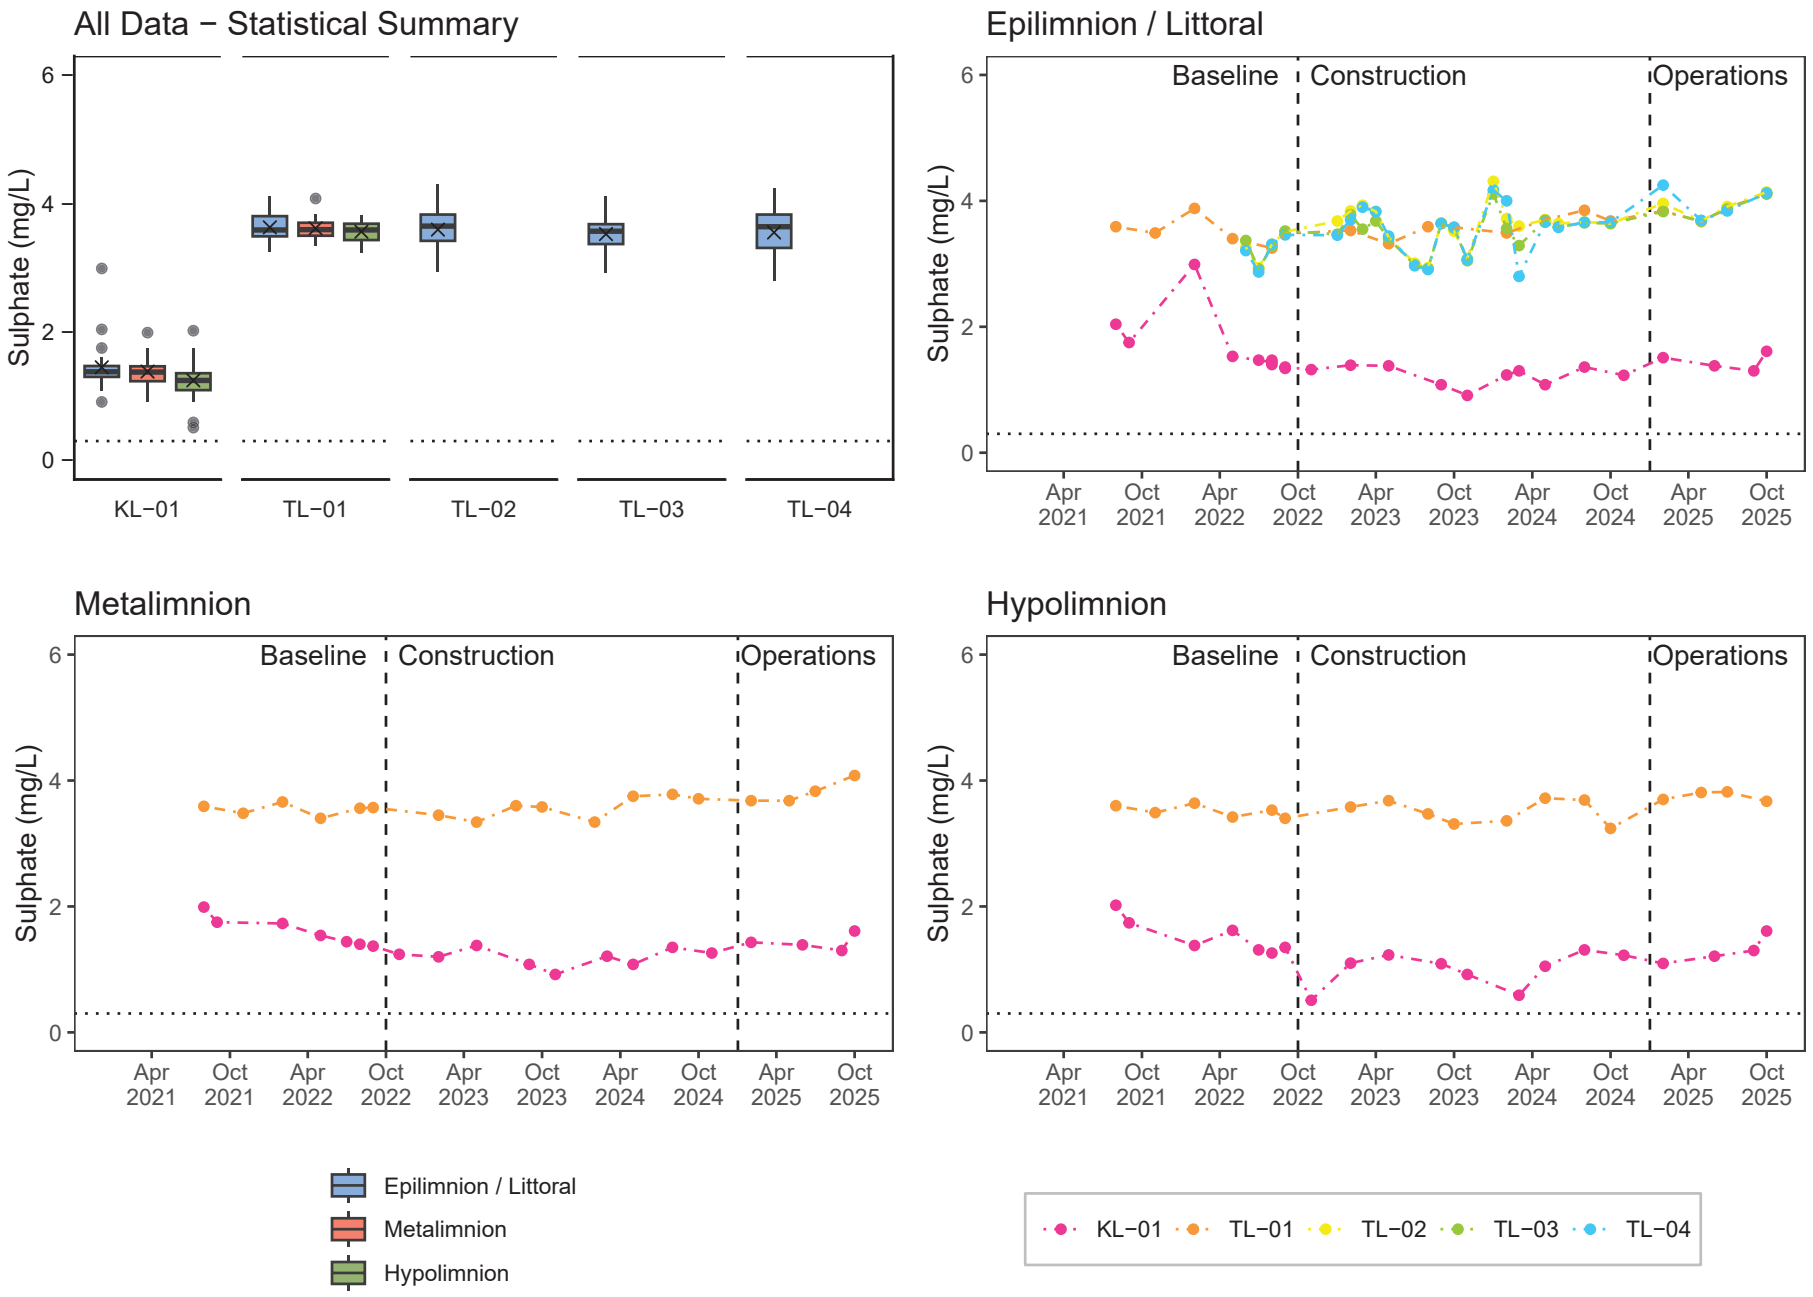
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.
BC WQG−AL long−term chronic guideline for chloride is 150 mg/L.

Figure A9−10: Chloride in AEMP Monitored Lakes, 2021 to 2025



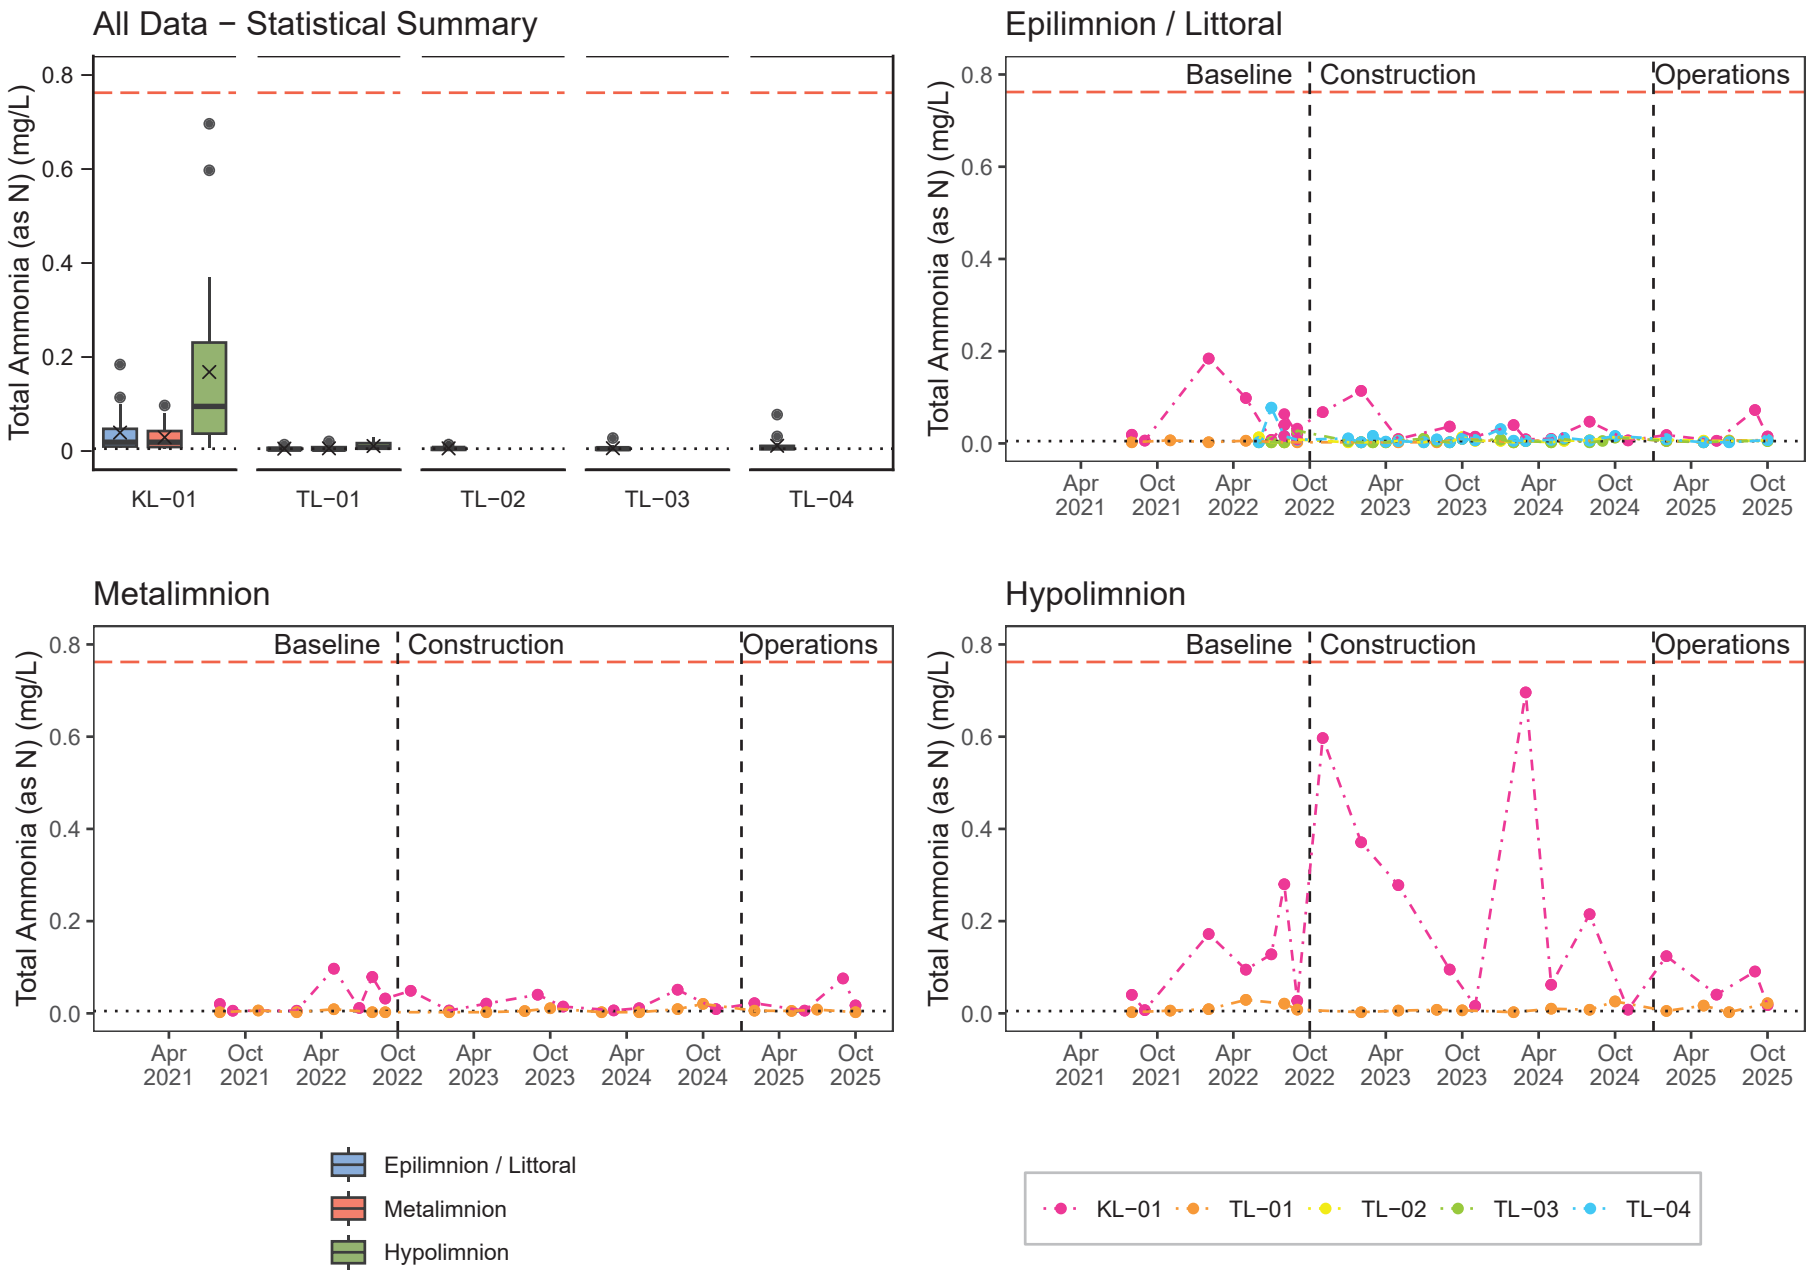
Notes: Dashed line indicates minimum detection limits.
Median BC WQG−AL short−term acute guideline for fluoride for Project lakes is 1.18 mg/L.

Figure A9−11: Fluoride in AEMP Monitored Lakes, 2021 to 2025



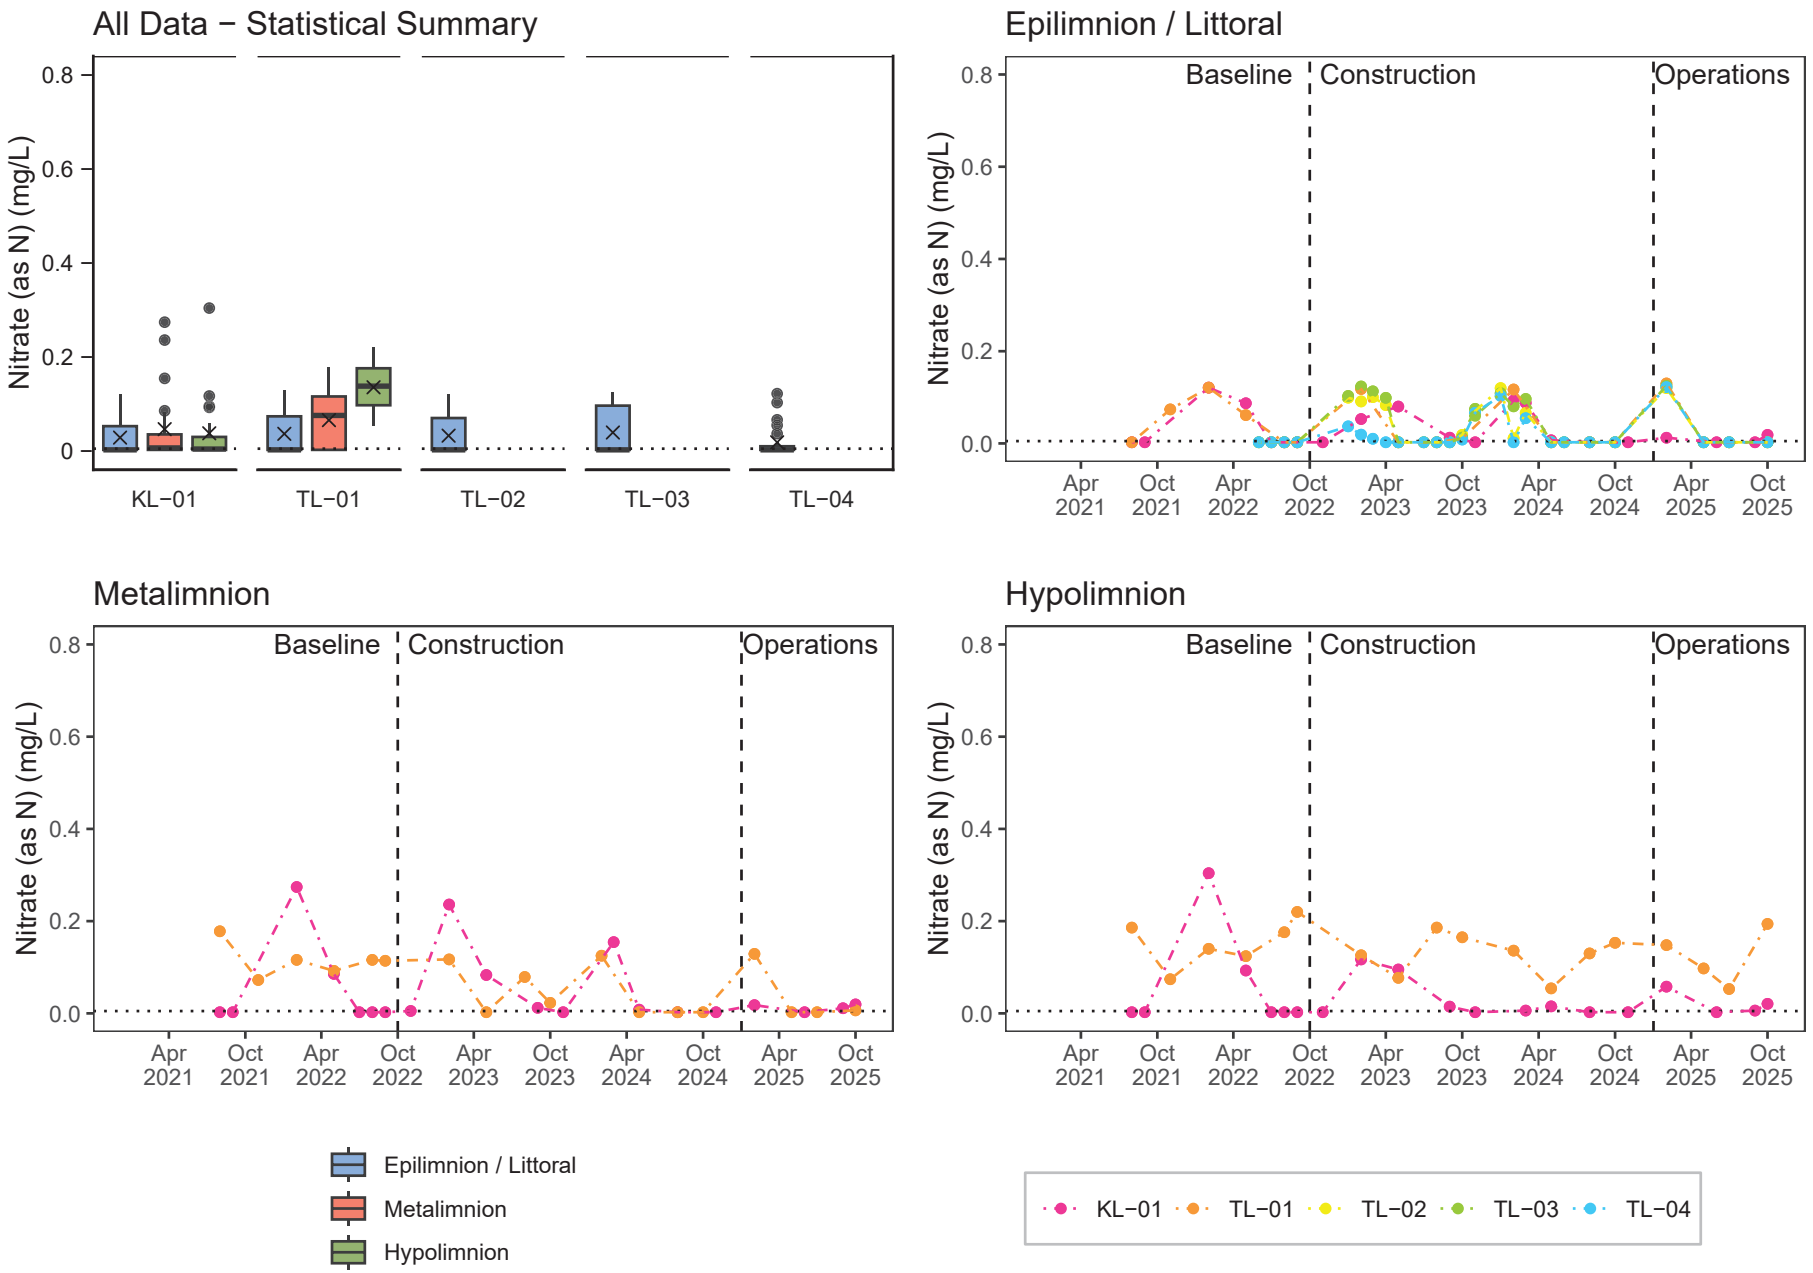
Notes: Dashed line indicates minimum detection limits.
Median BC WQG−AL long−term chronic guideline for sulphate for Project lakes is 218 mg/L.

Figure A9−12: Sulphate in AEMP Monitored Lakes, 2021 to 2025



Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.
Median pH and temperature dependent BC WQG−AL long−term guideline for total ammonia−N is 0.762 mg/L.

Figure A9−13: Total Ammonia−N in AEMP Monitored Lakes, 2021 to 2025

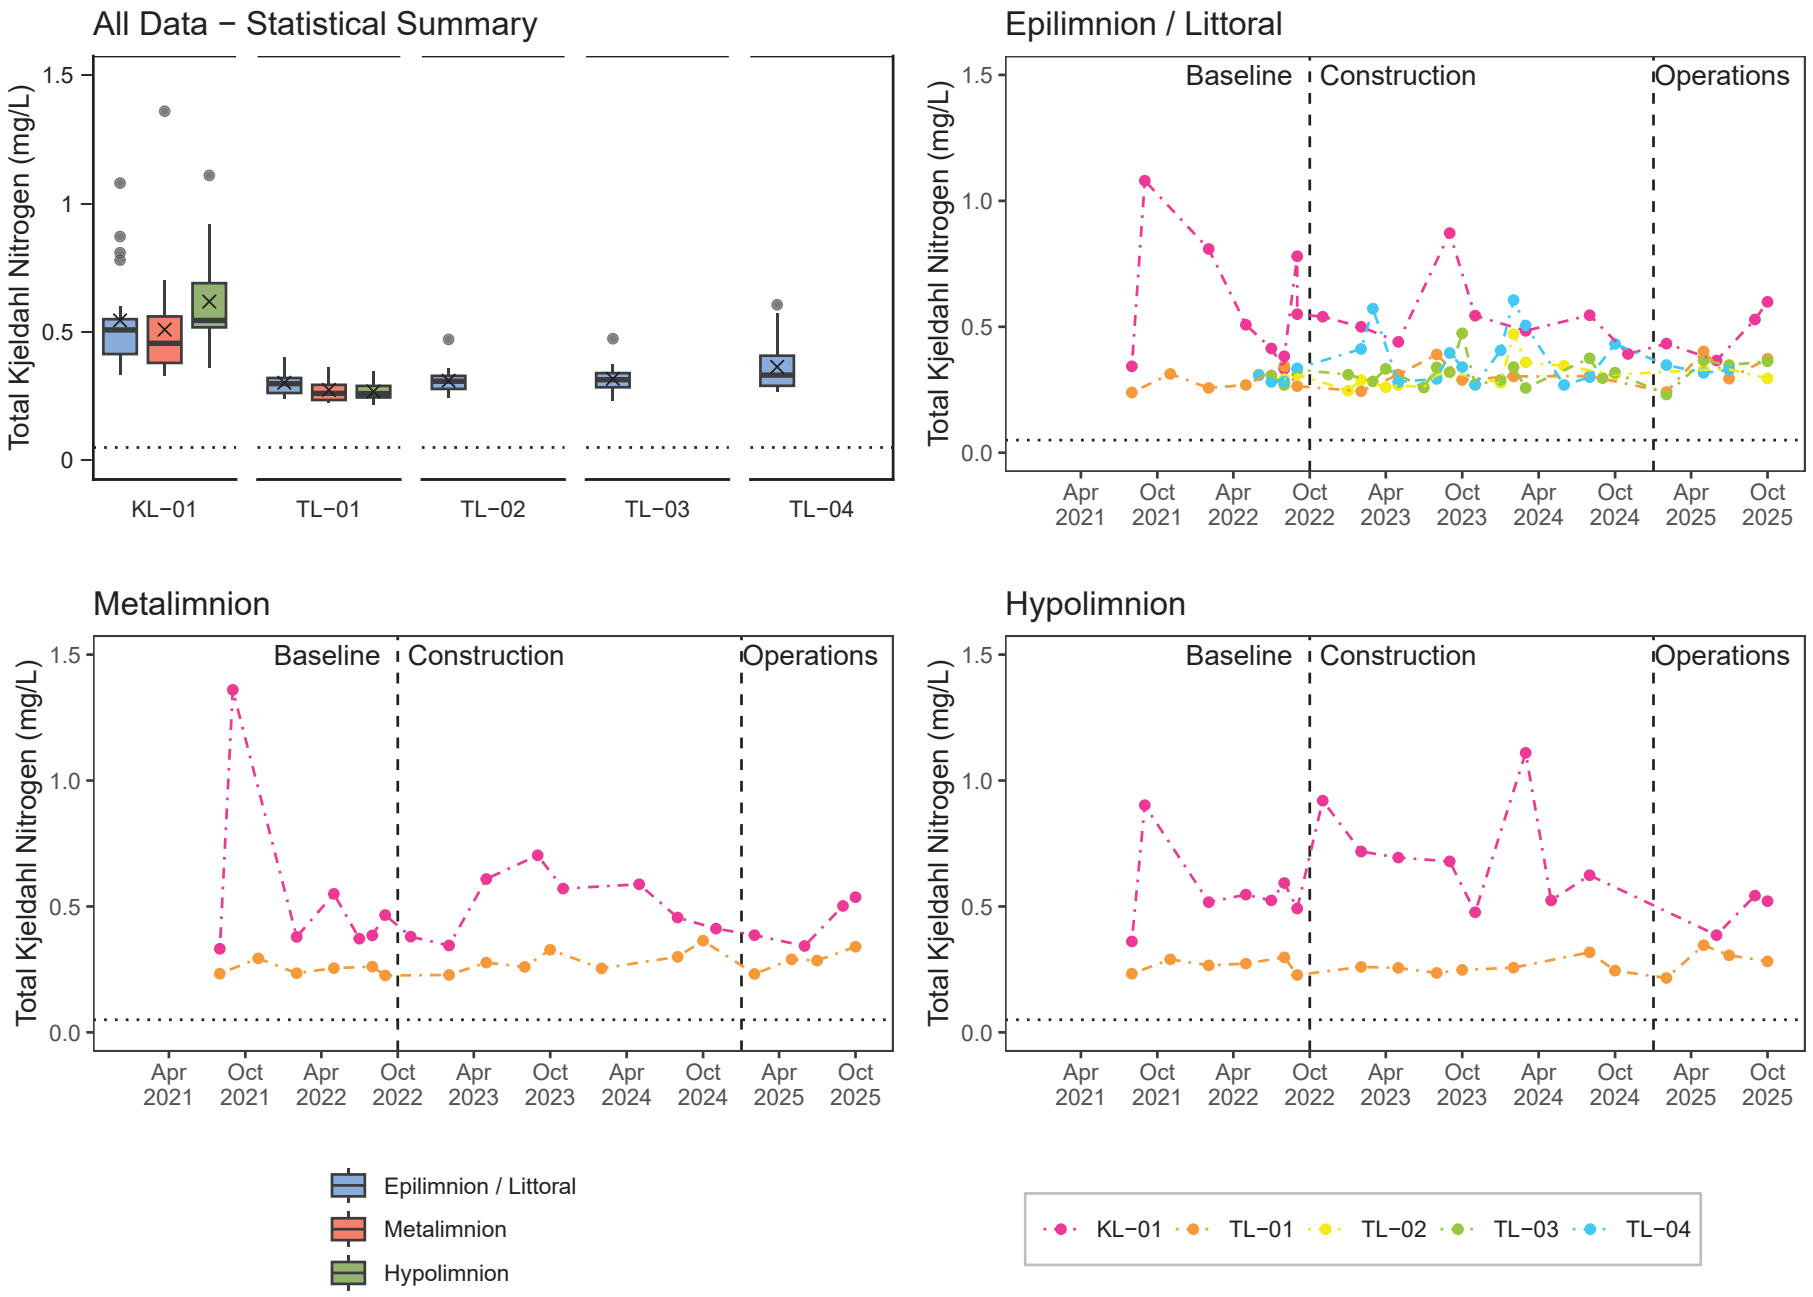


Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.
BC WQG−AL long−term chronic guideline for nitrate−N is 3 mg/L.

Figure A9−14: Nitrate−N in AEMP Monitored Lakes, 2021 to 2025

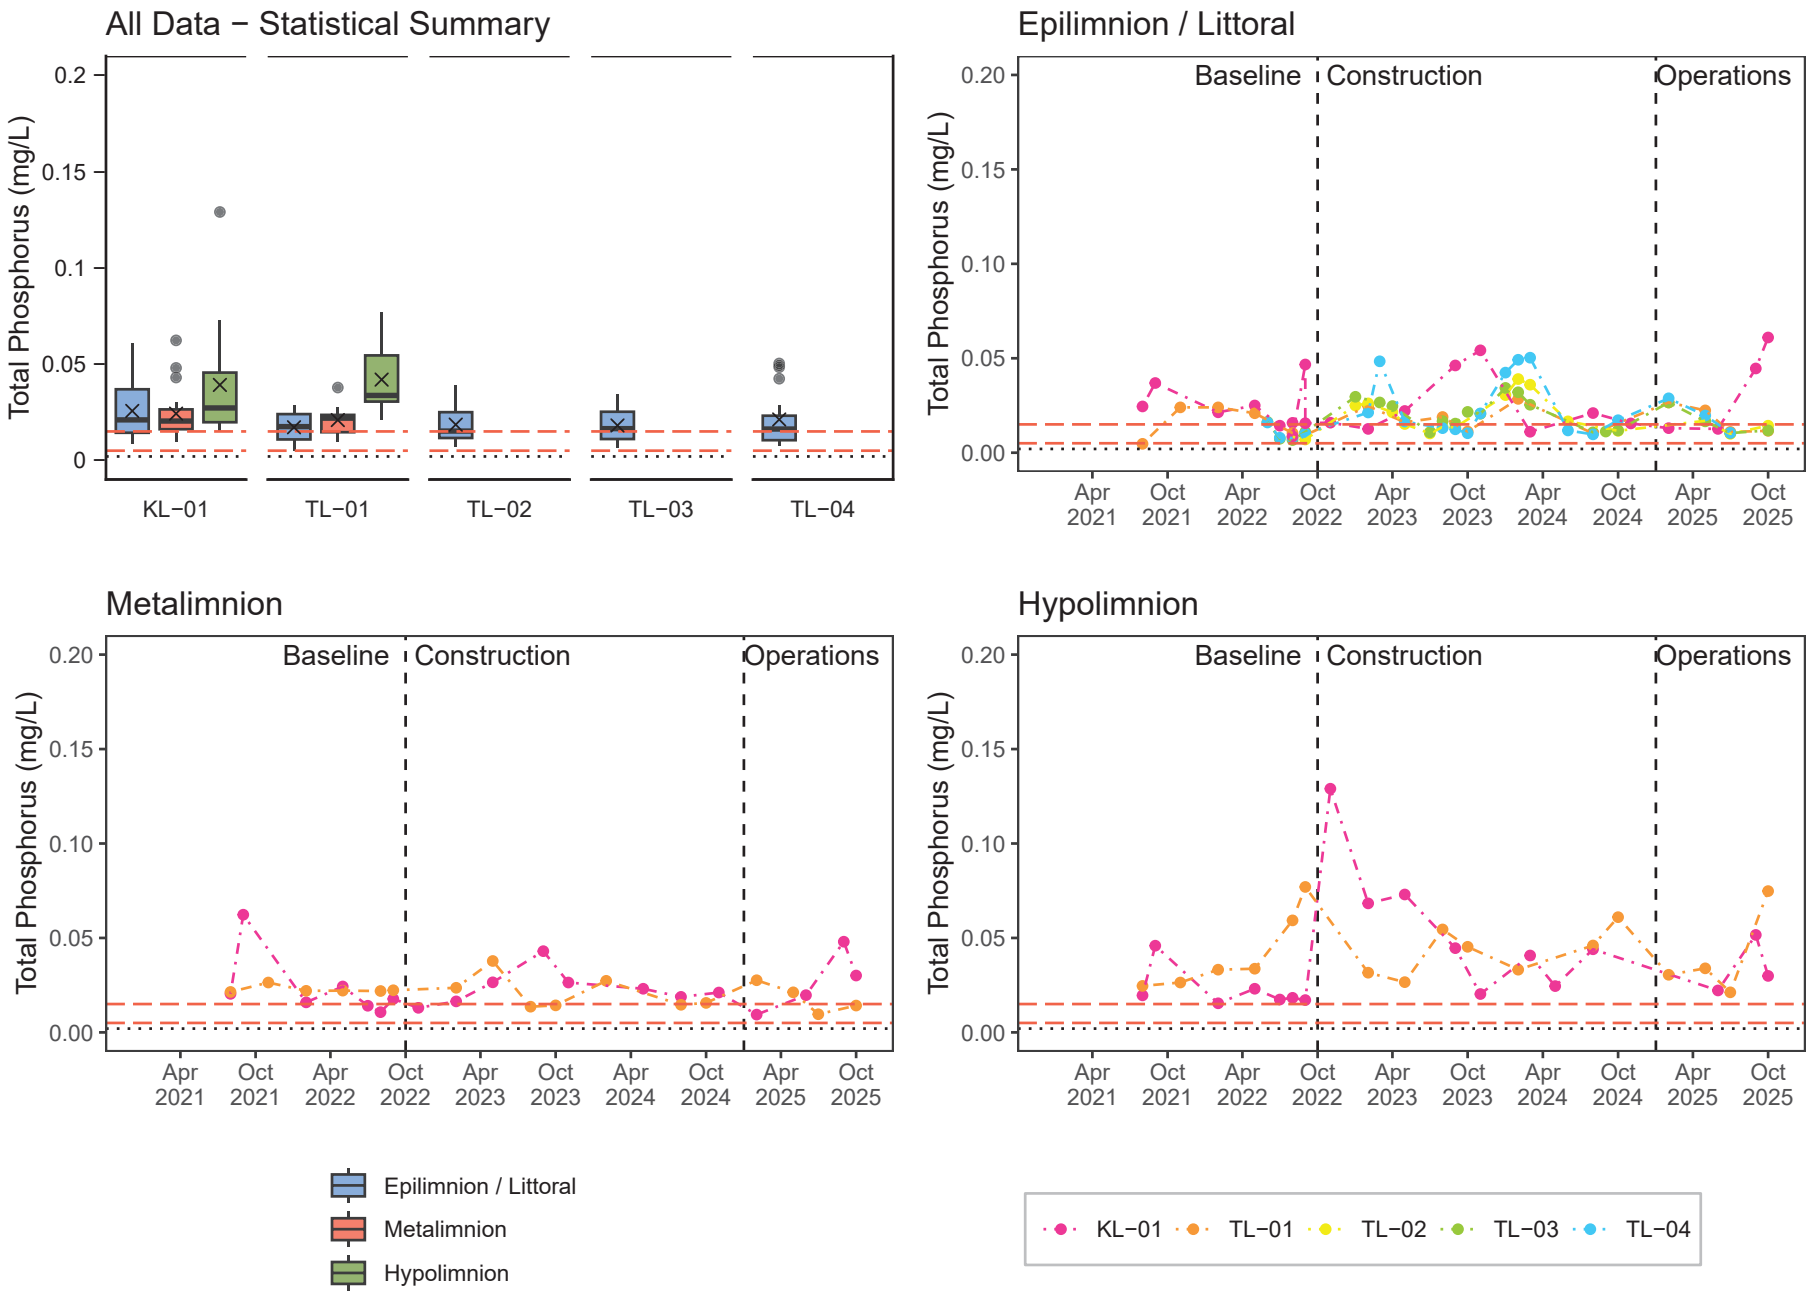
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.
Median BC WQG−AL long−term chronic guideline for nitrite for Project lakes is 0.02 mg/L.

Figure A9−15: Nitrite−N in AEMP Monitored Lakes, 2021 to 2025



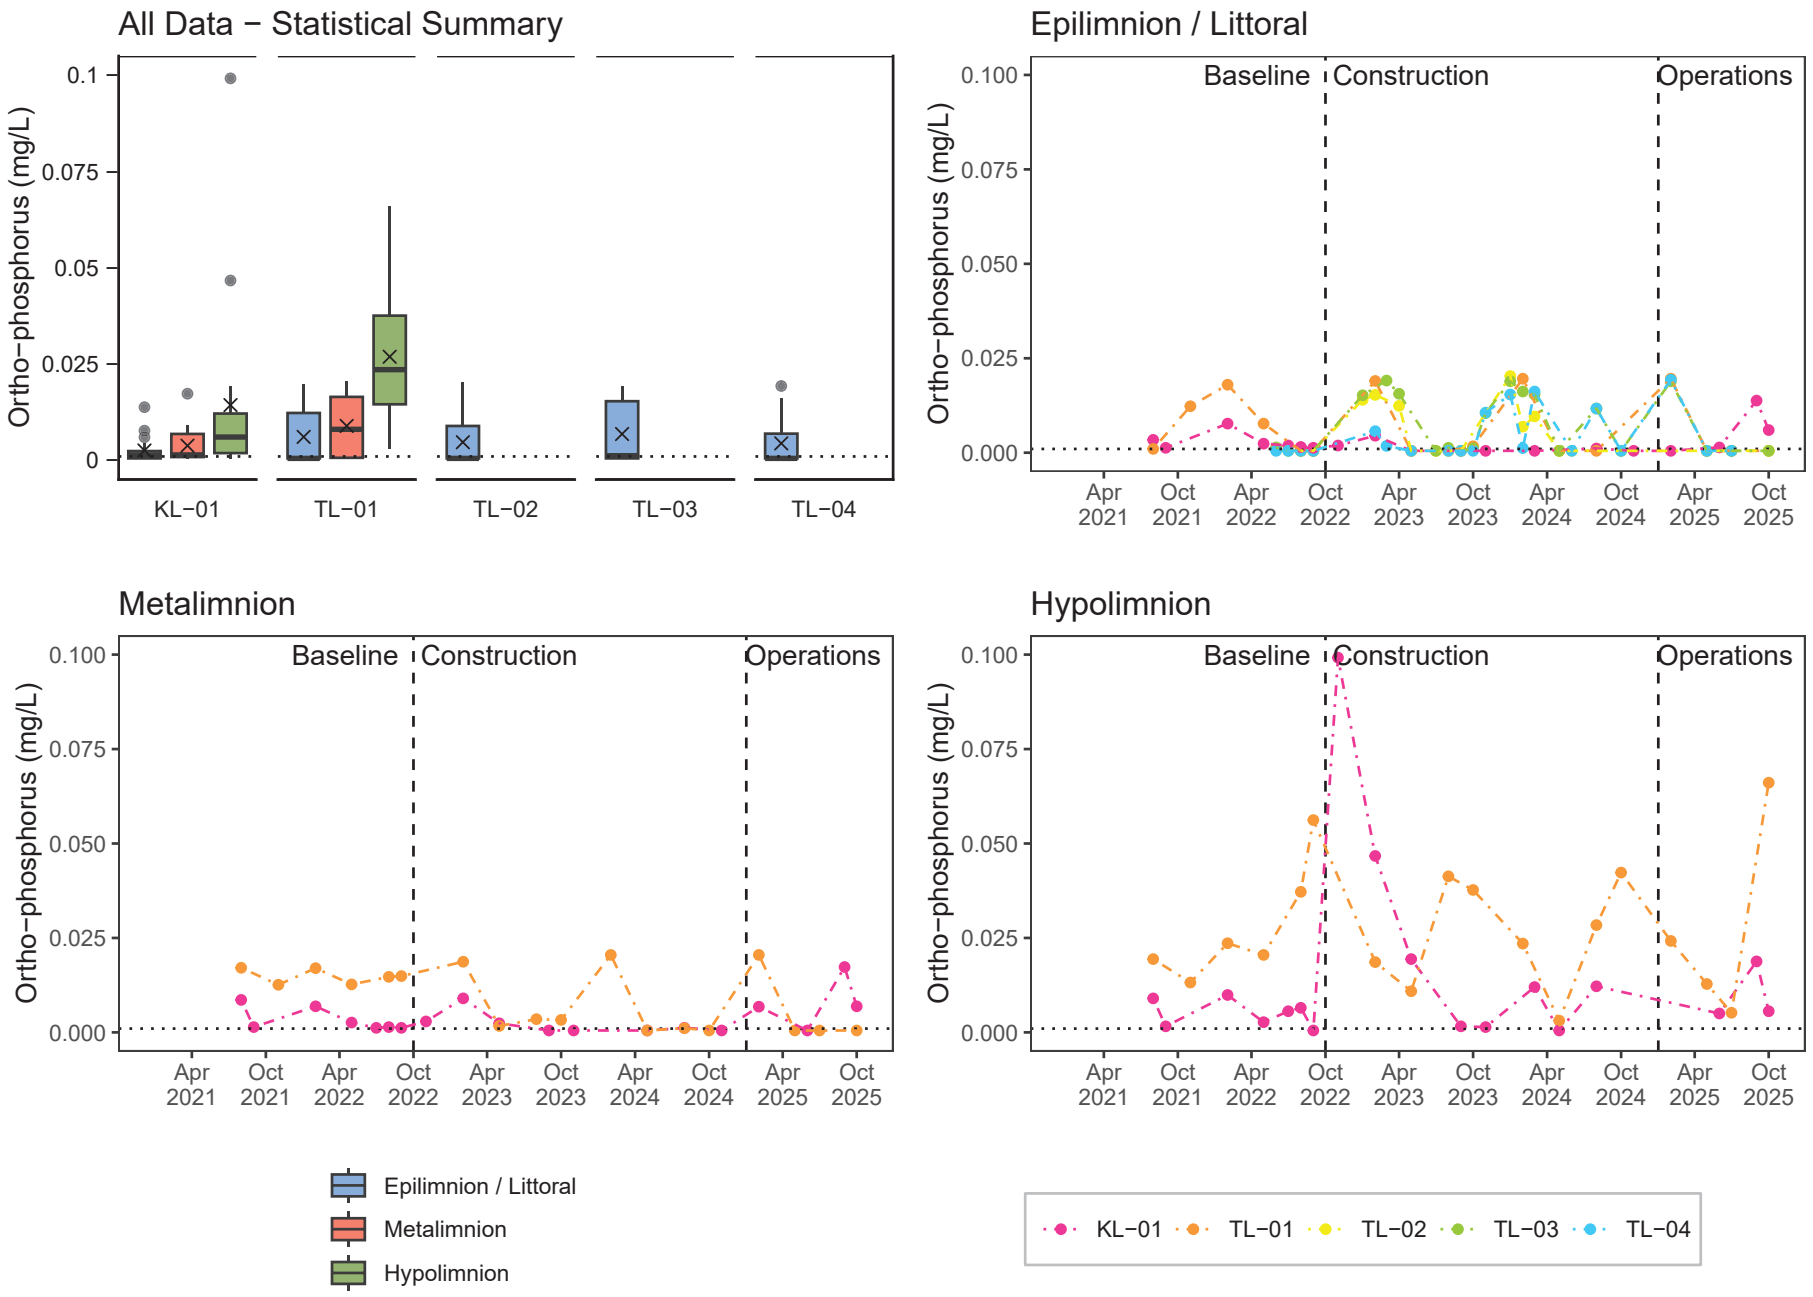
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−16: Total Kjeldahl Nitrogen in AEMP Monitored Lakes, 2021 to 2025



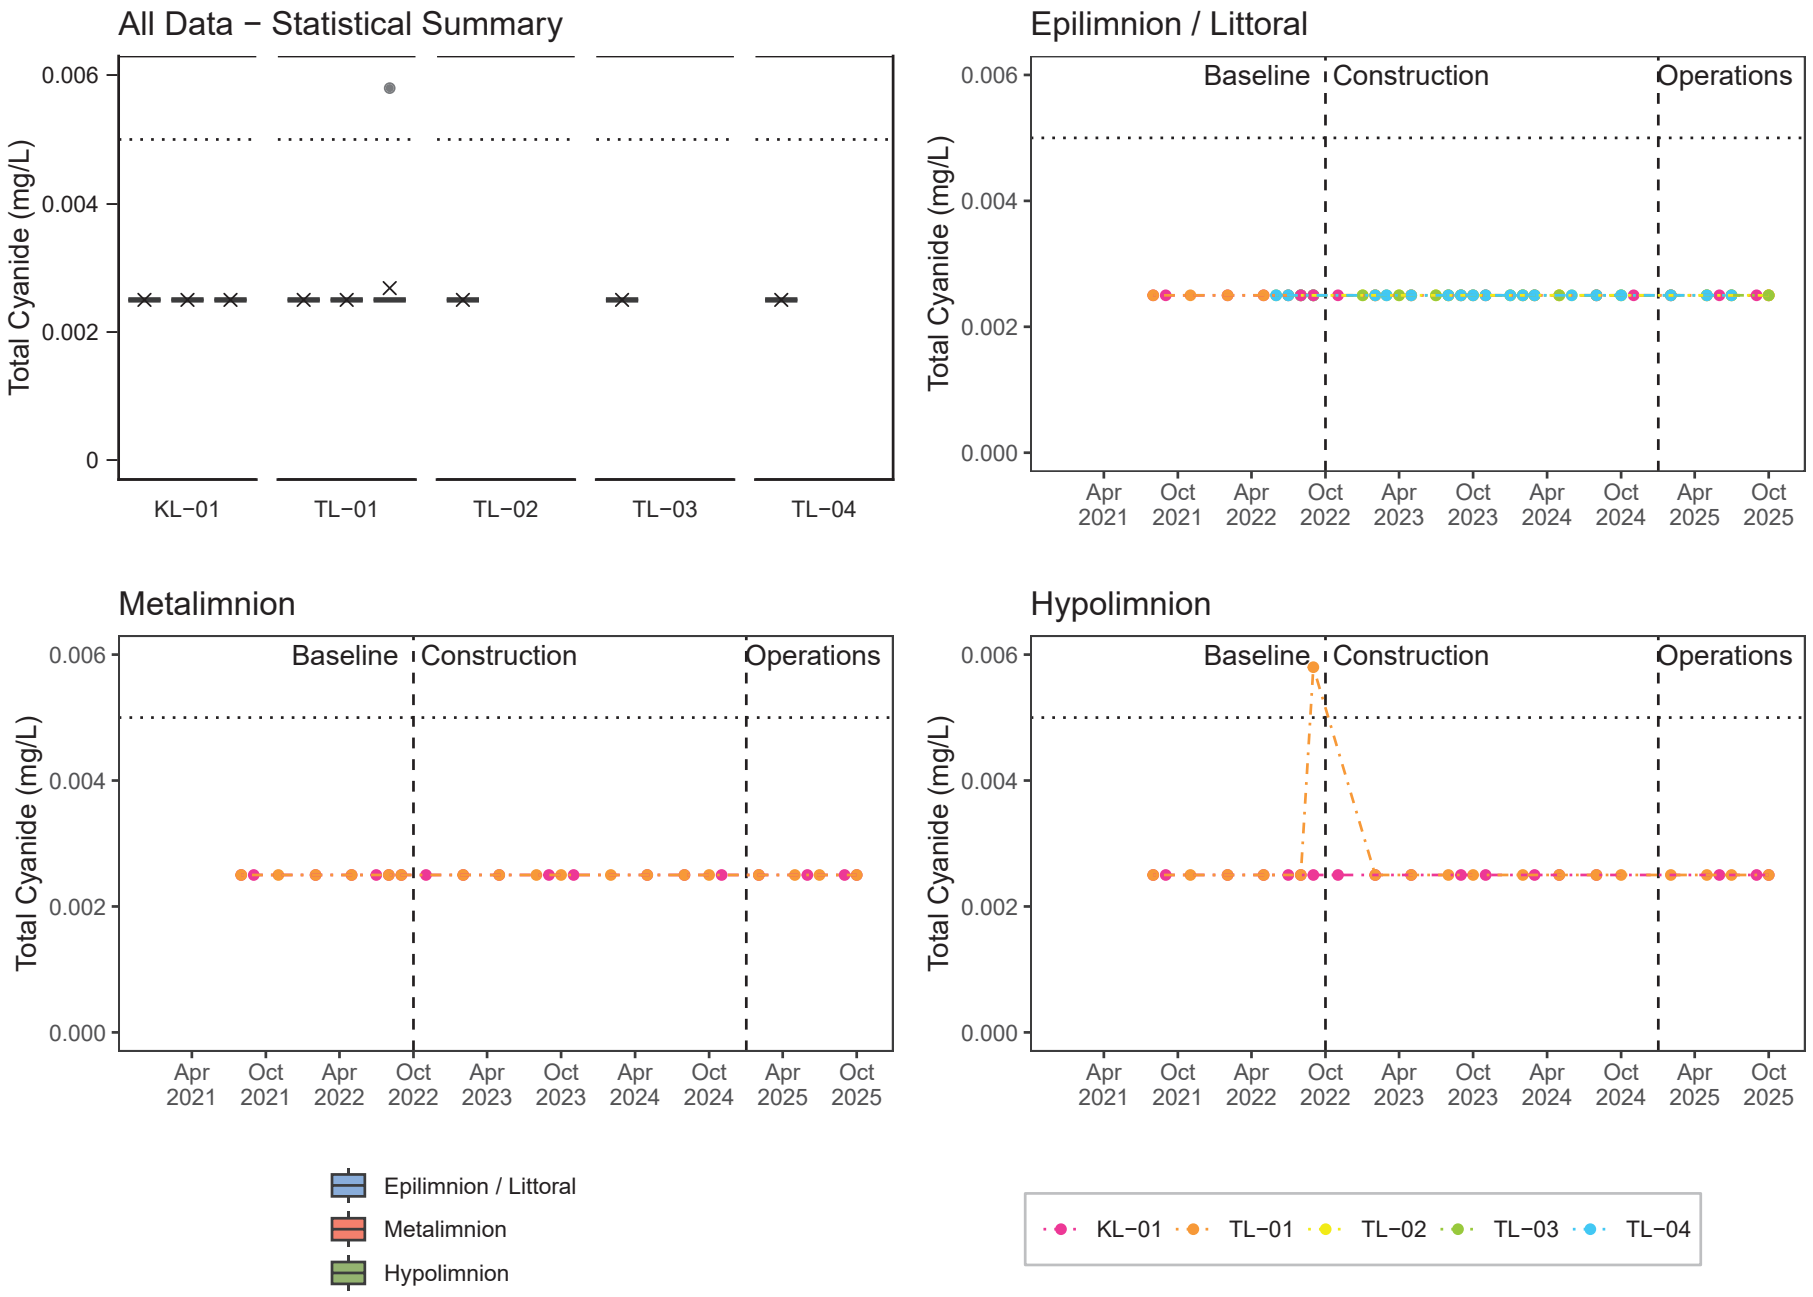
Notes: Dashed line indicates minimum detection limits.
Red dashed lines indicate BC WQG−AL ranges for total phosphorus in lakes.

Figure A9−17: Total Phosphorus in AEMP Monitored Lakes, 2021 to 2025



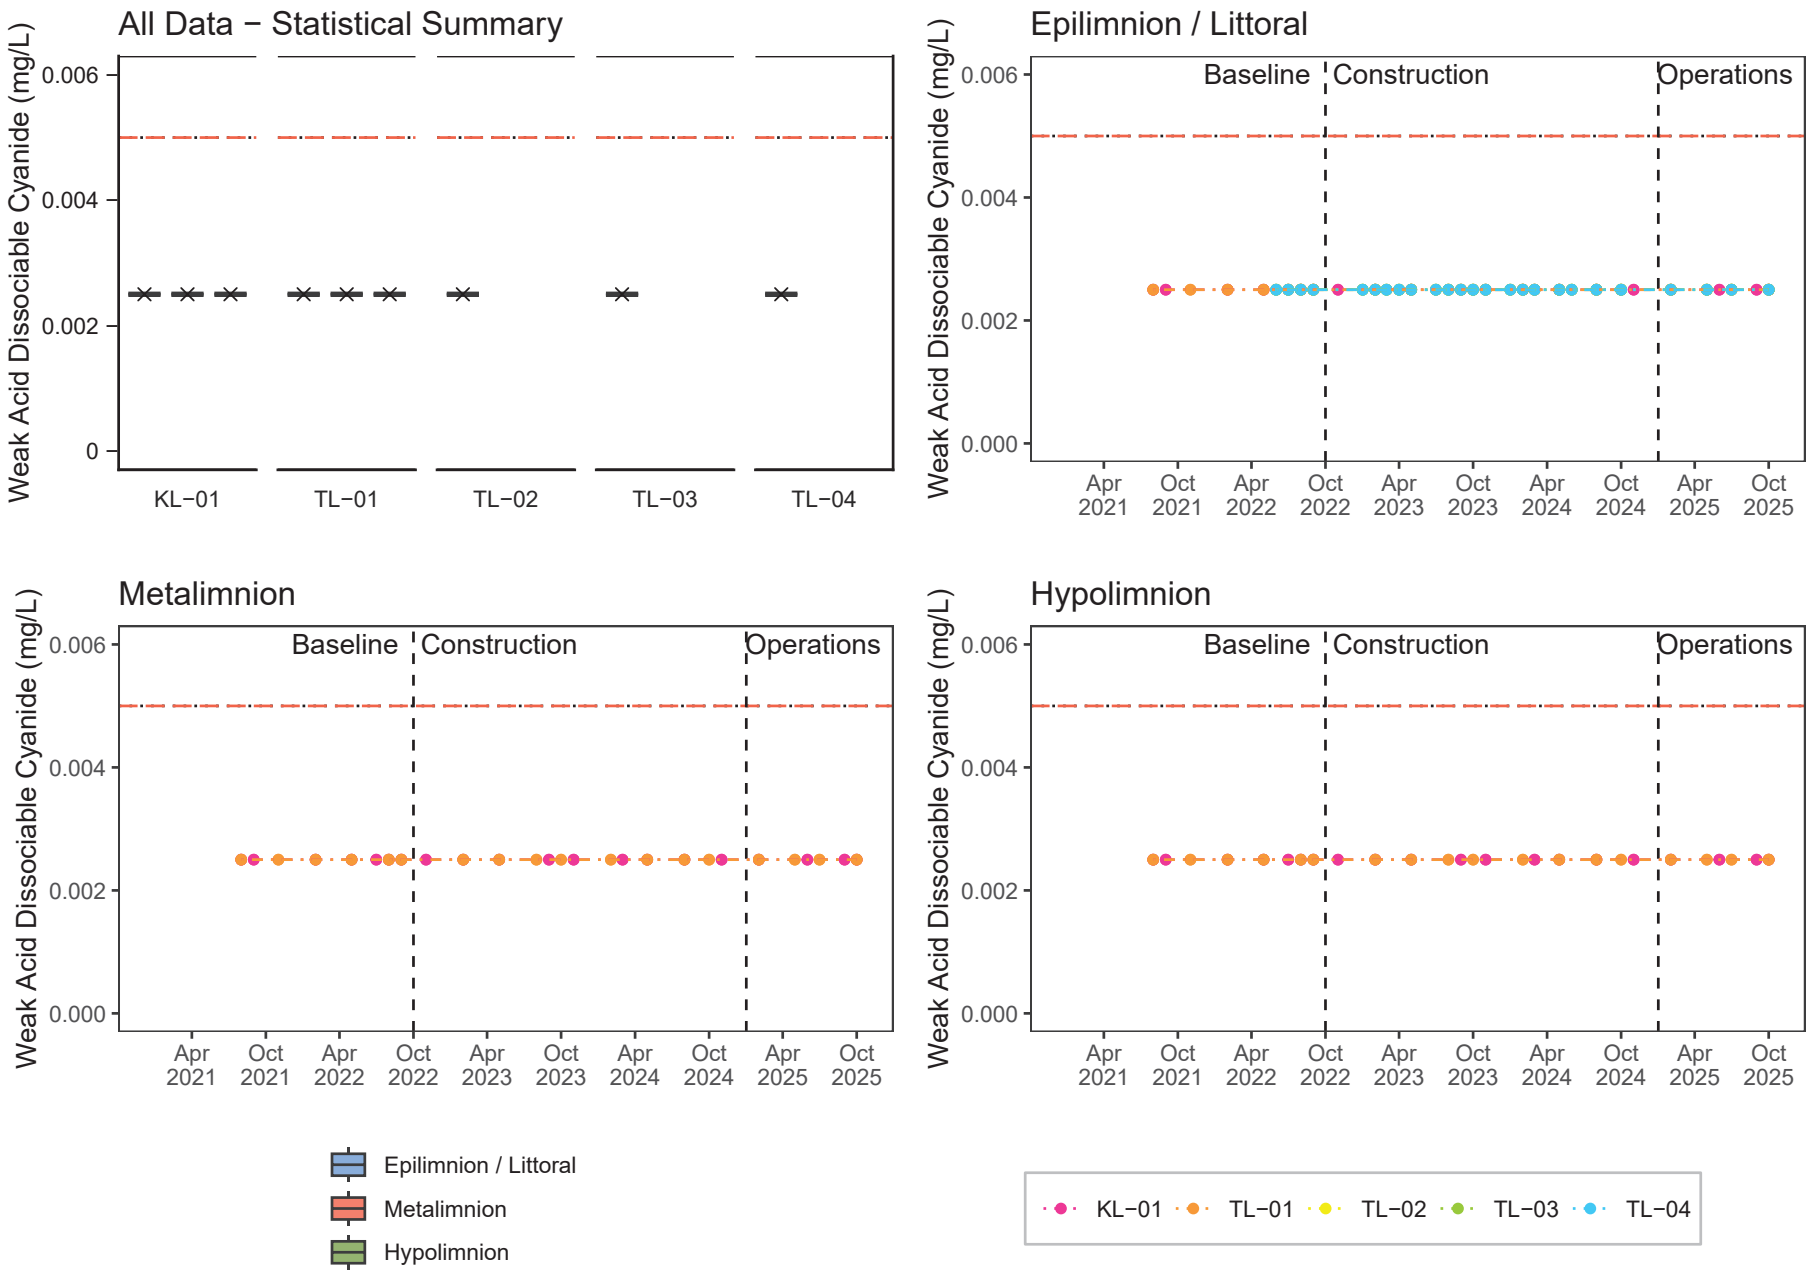
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−18: Orthophosphate in AEMP Monitored Lakes, 2021 to 2025



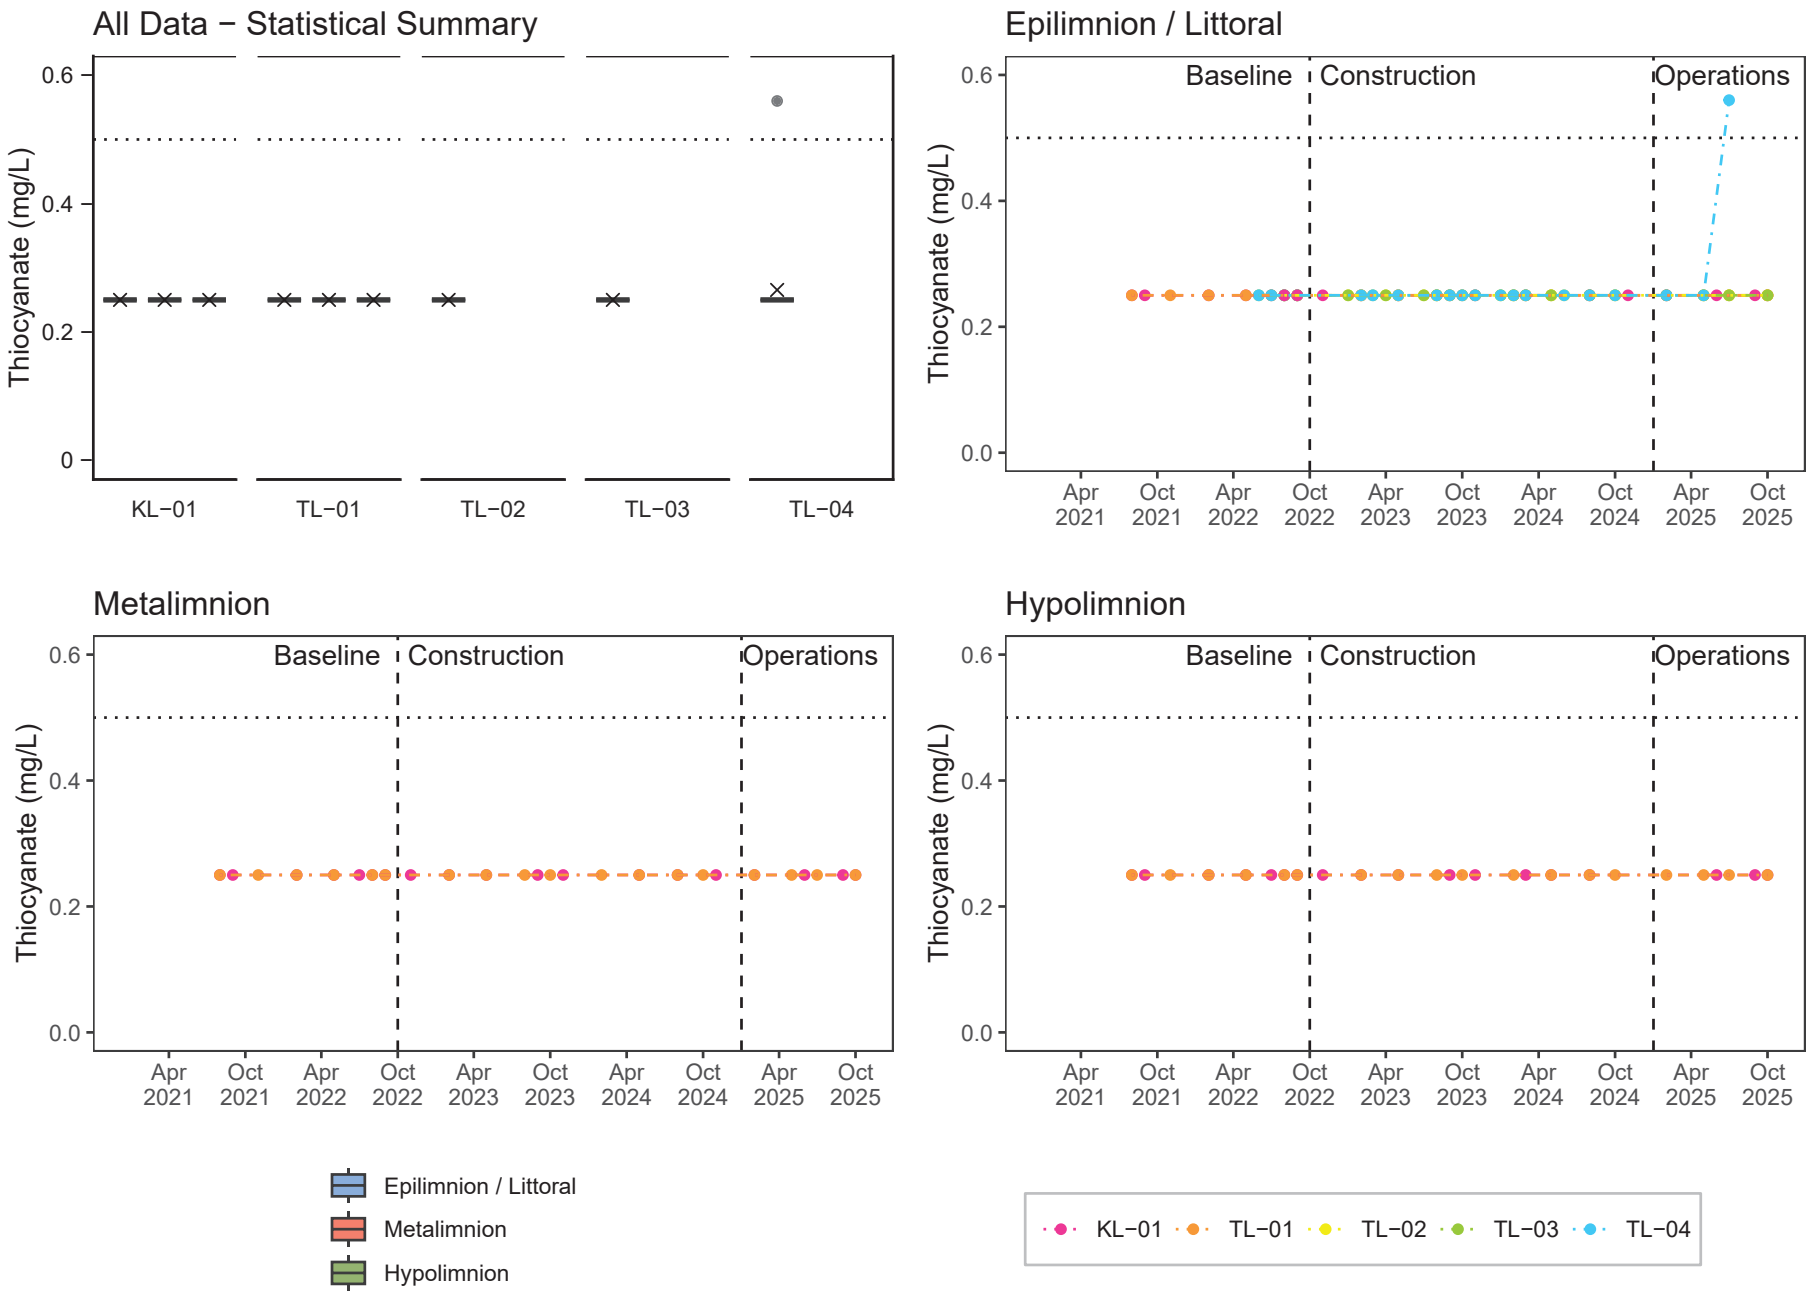
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−19: Total Cyanide in AEMP Monitored Lakes, 2021 to 2025



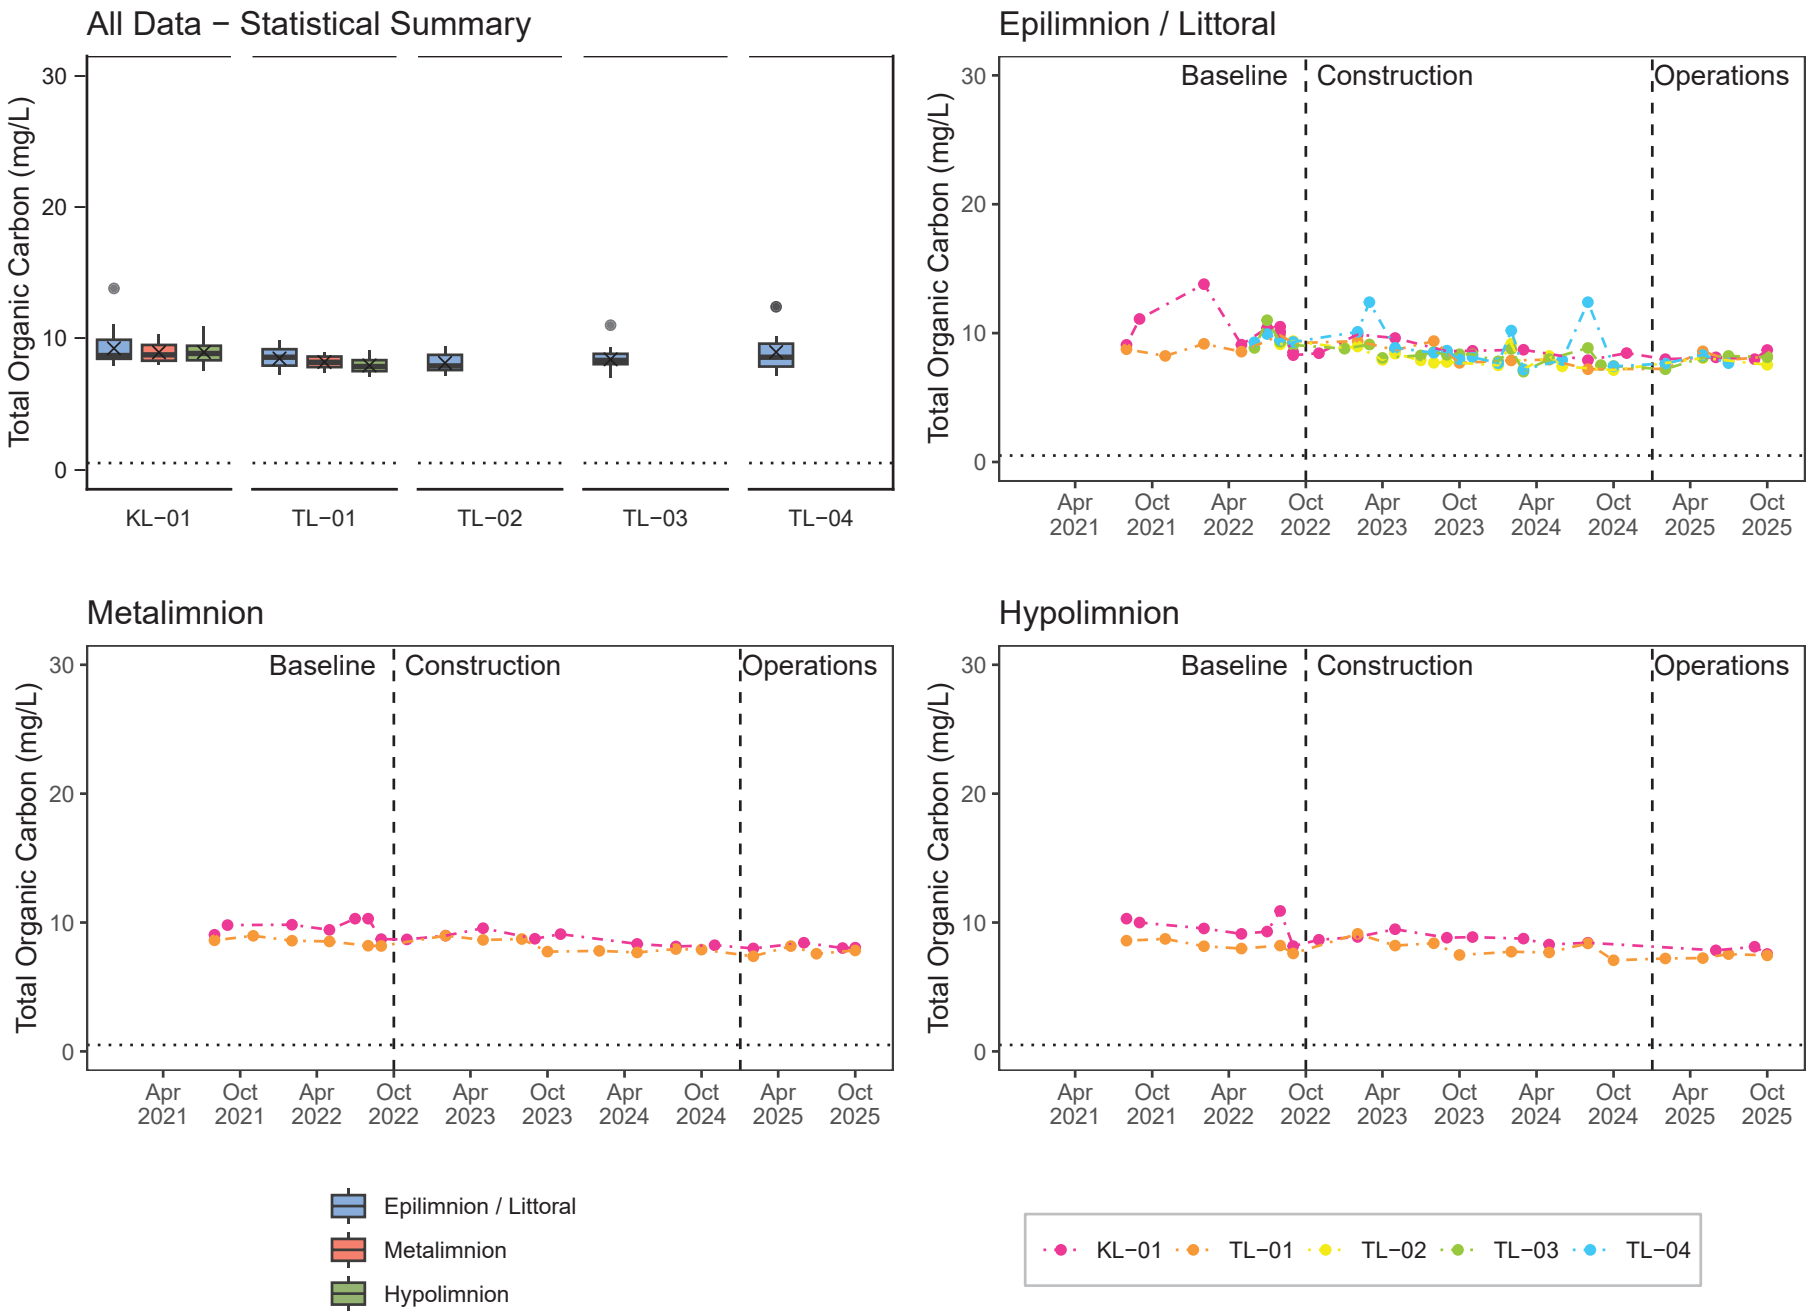
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.
BC WQG−AL long−term chronic guideline for weak acid dissociable cyanide is 0.005 mg/L.

Figure A9−20: Weak Acid Dissociable Cyanide in AEMP Monitored Lakes, 2021 to 2025



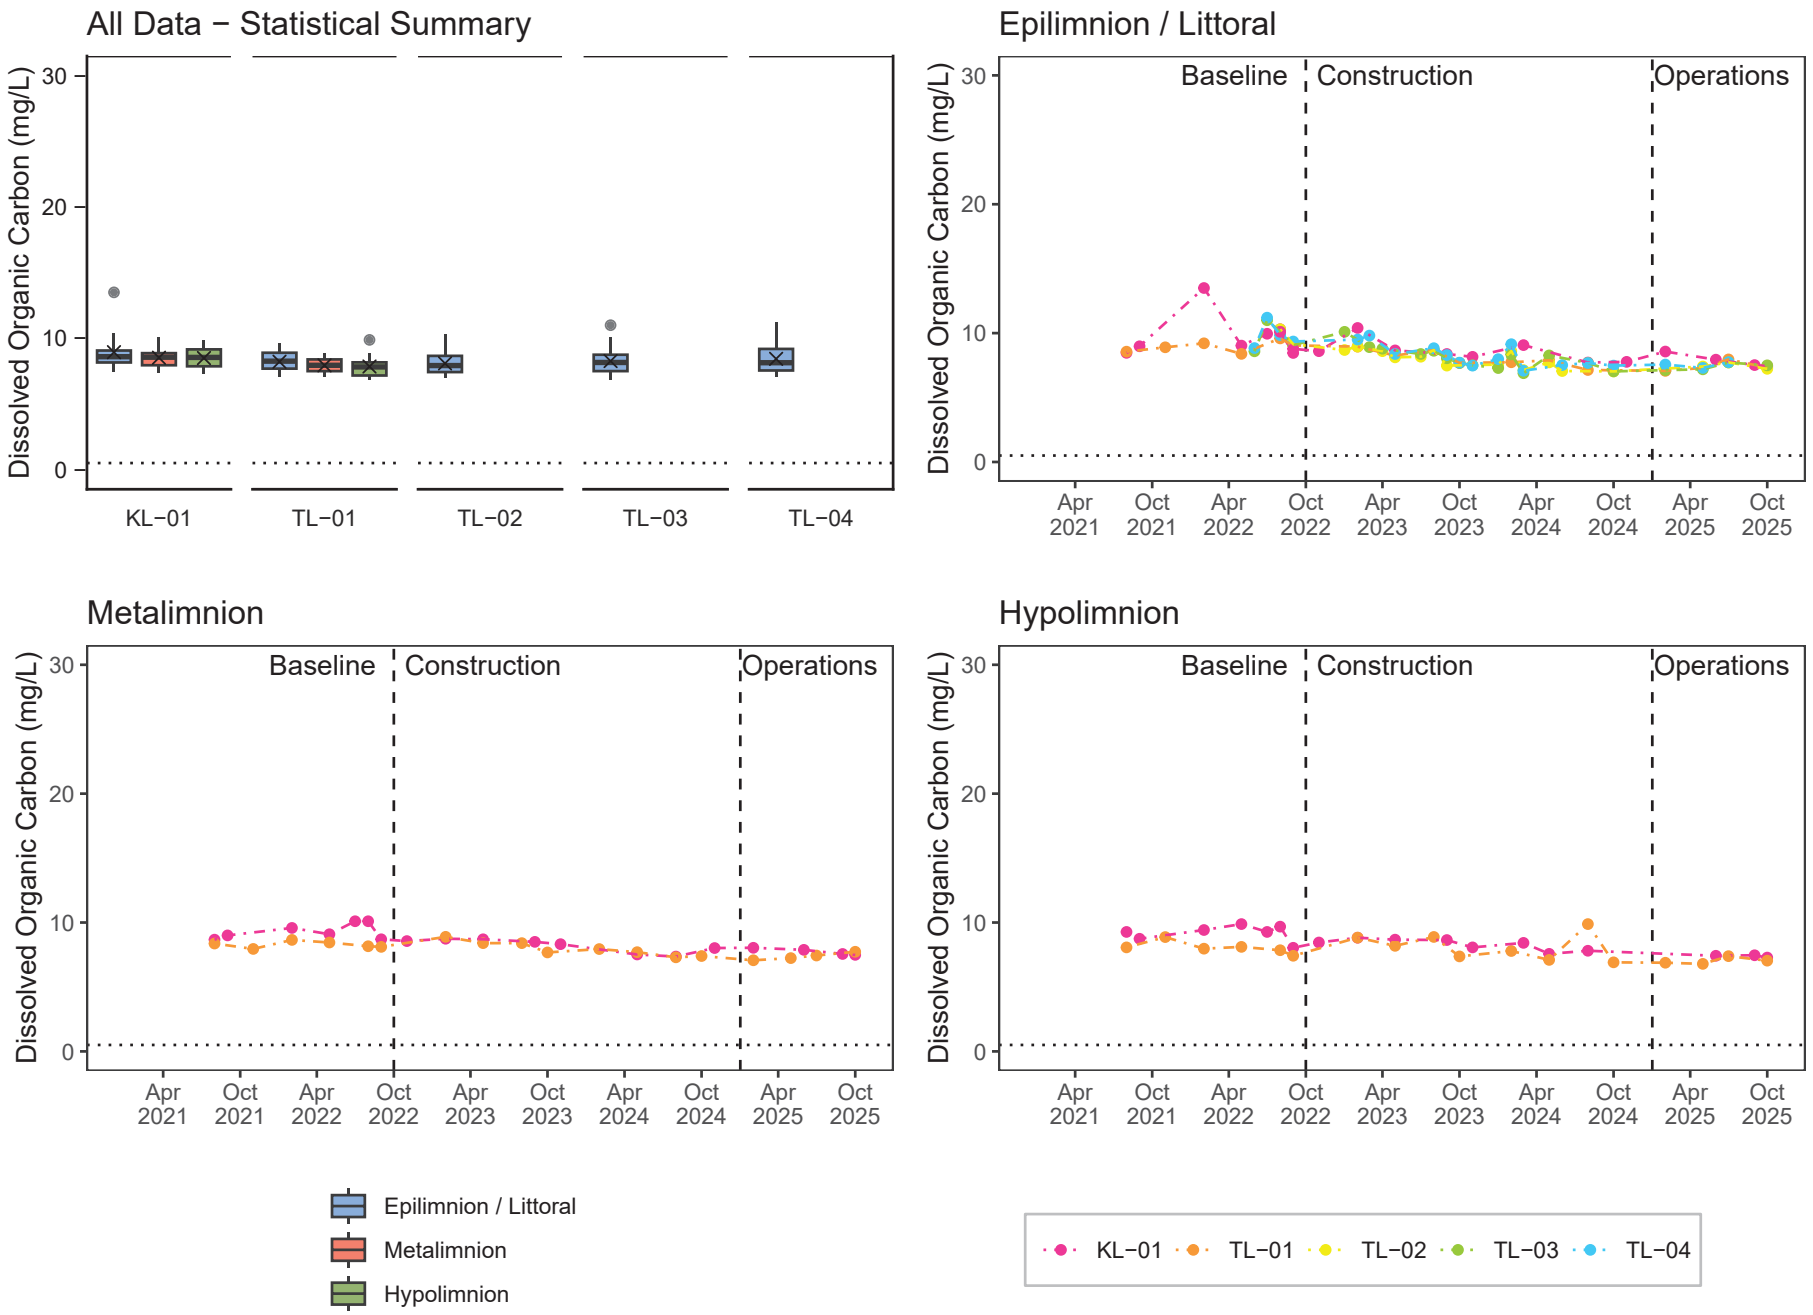
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−21: Thiocyanate in AEMP Monitored Lakes, 2021 to 2025



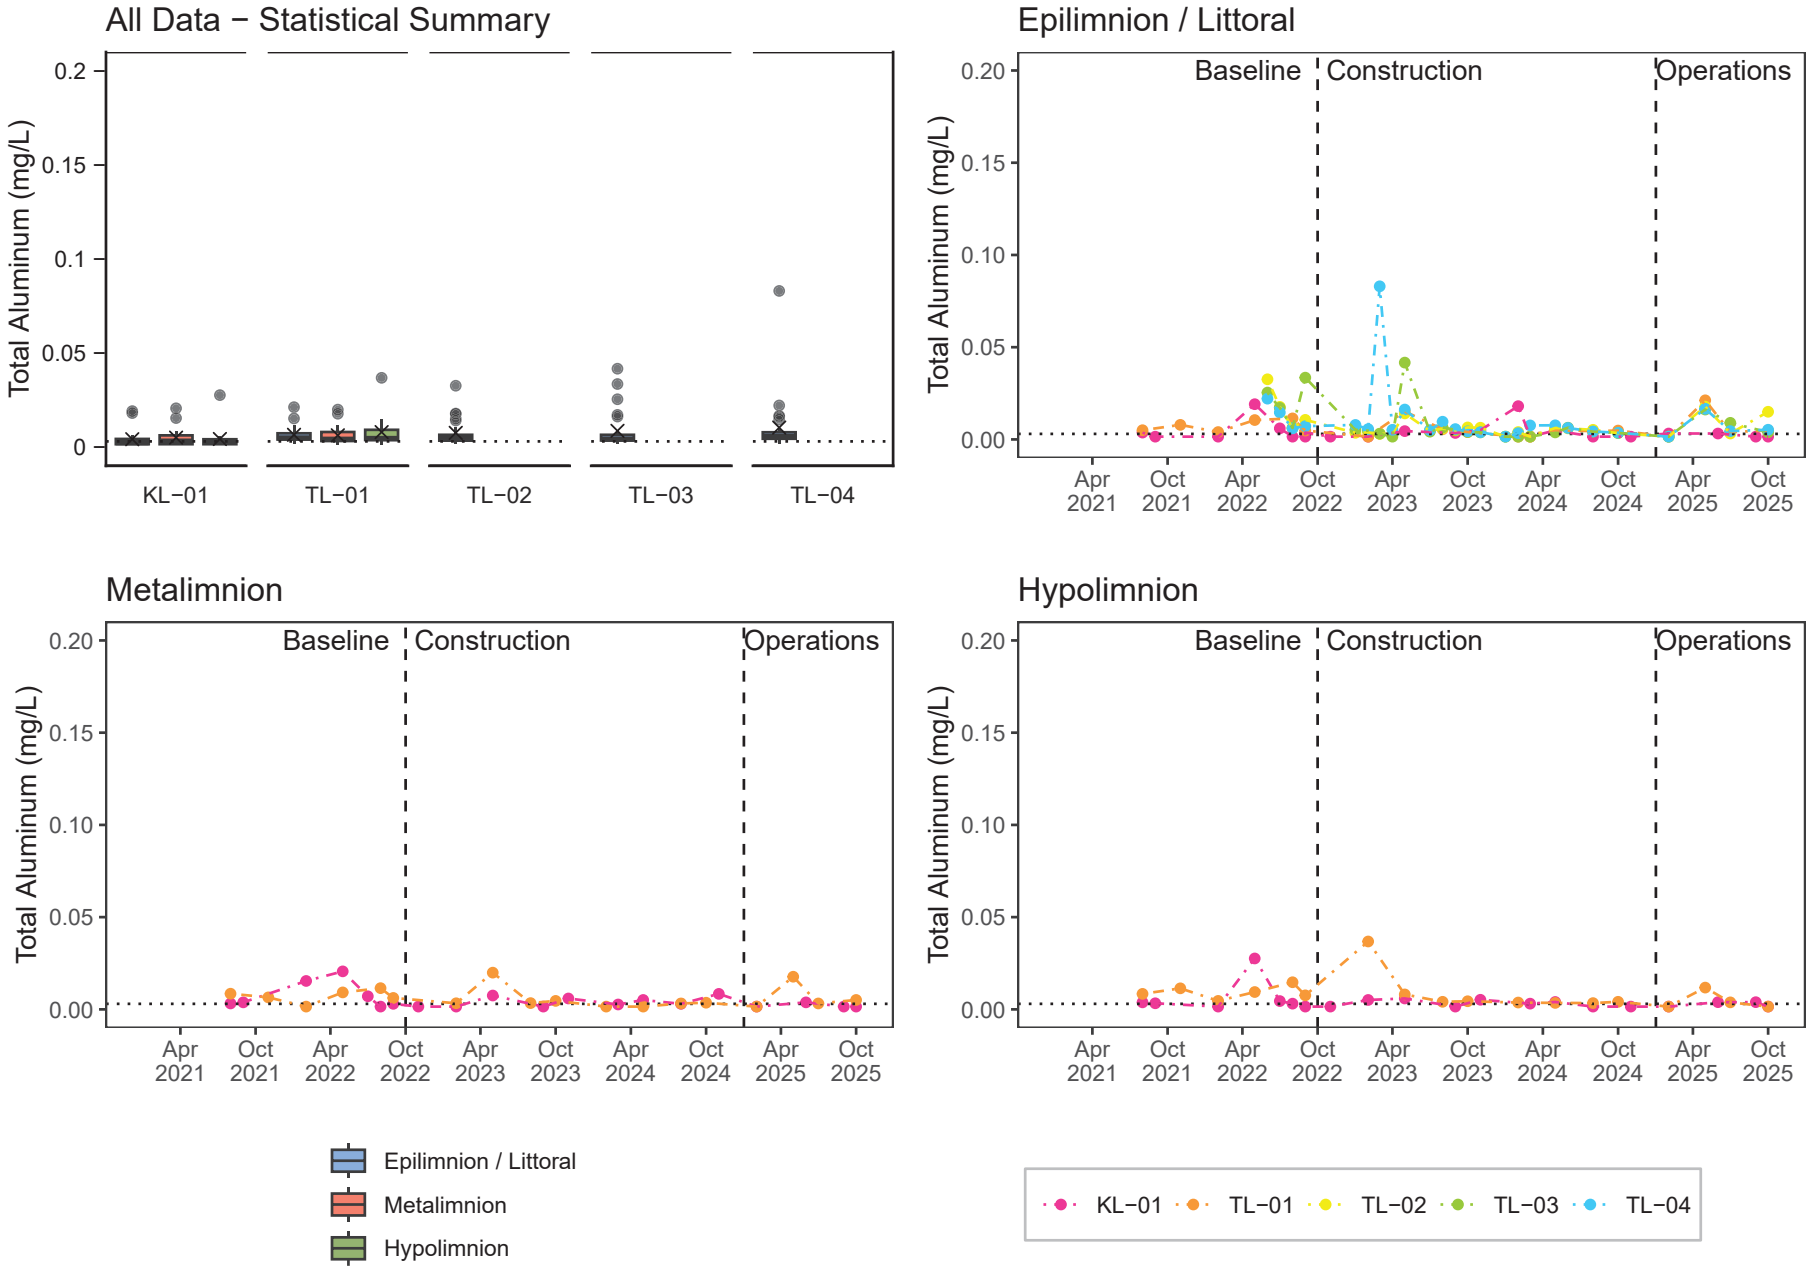
Notes: Dashed line indicates minimum detection limits.

Figure A9−22: Total Organic Carbon in AEMP Monitored Lakes, 2021 to 2025



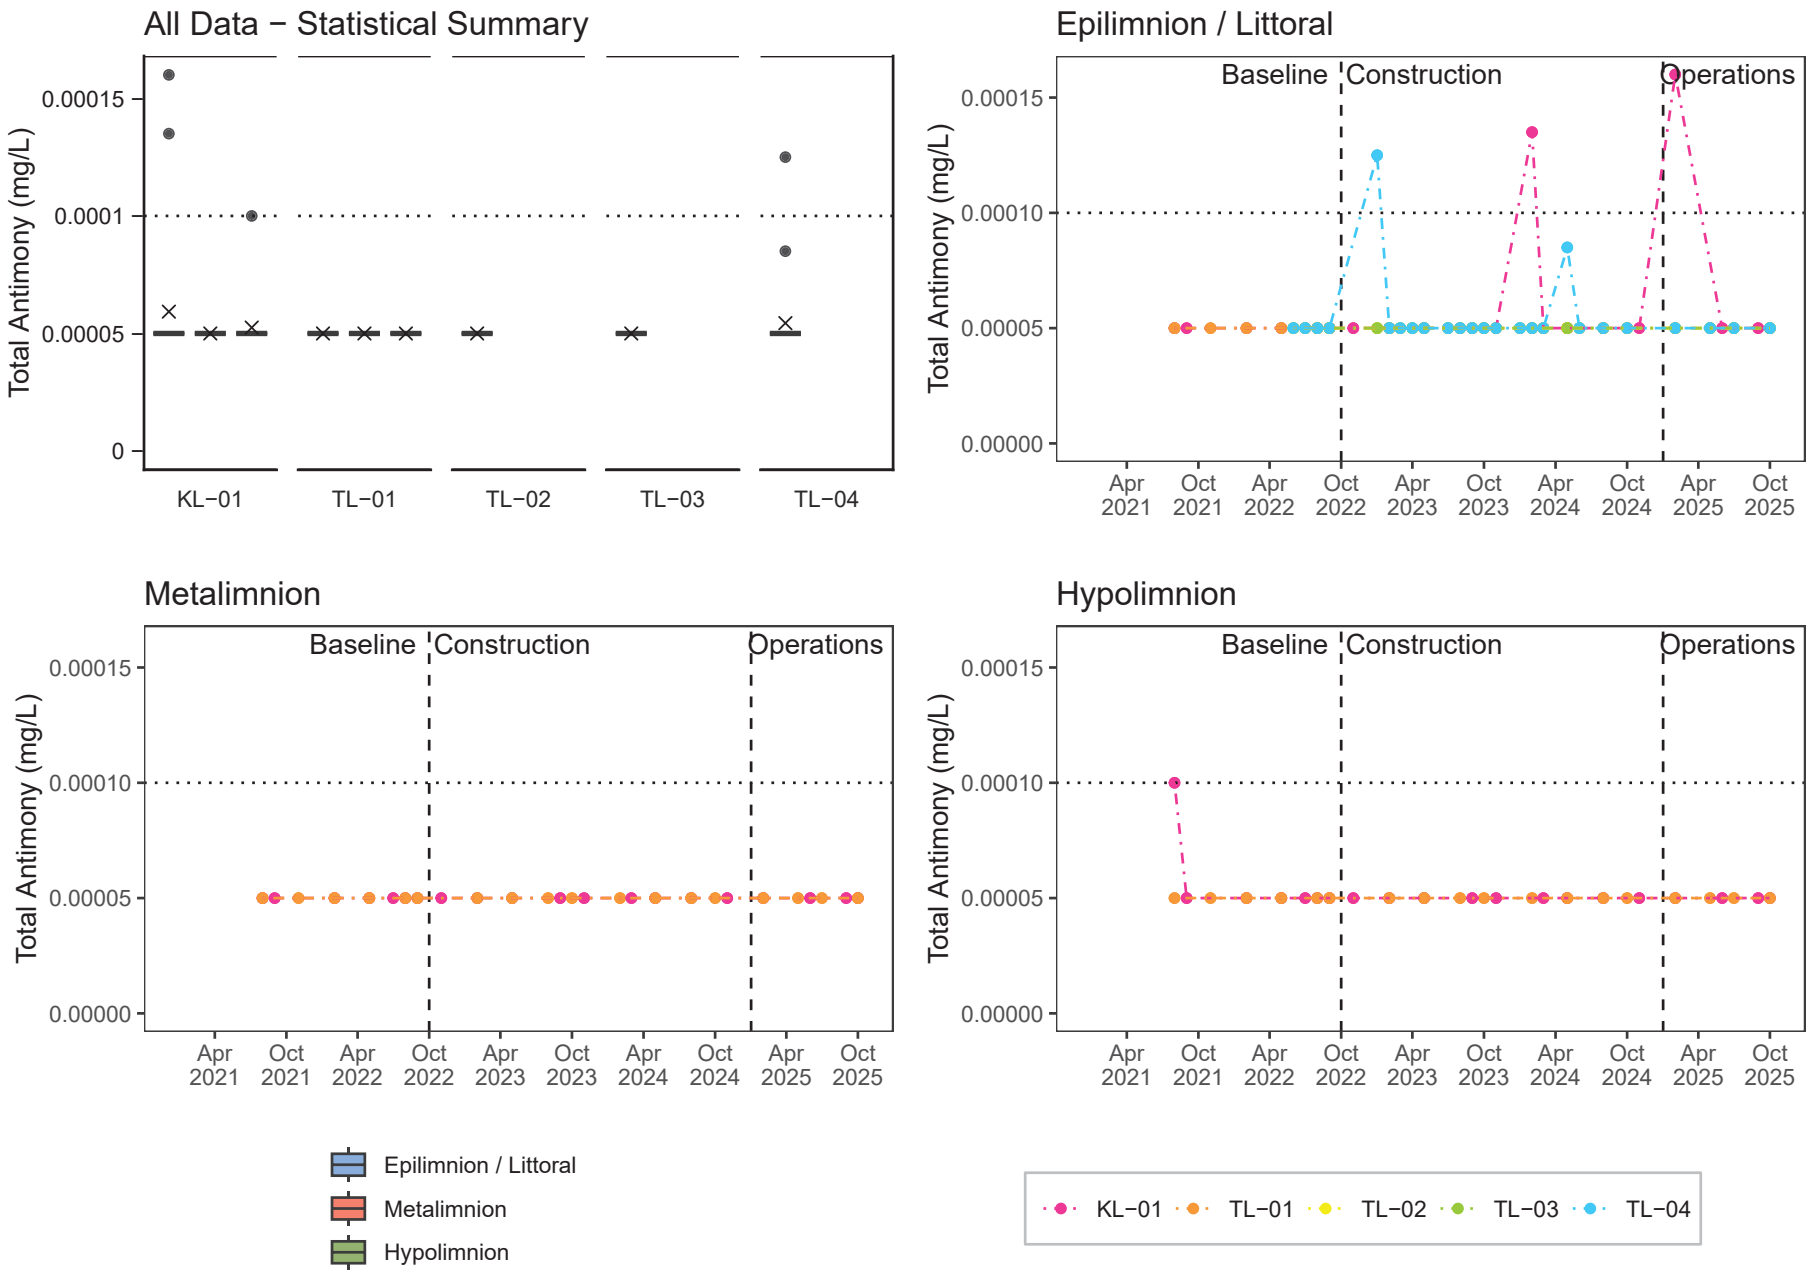
Notes: Dashed line indicates minimum detection limits.

Figure A9−23: Dissolved Organic Carbon in AEMP Monitored Lakes, 2021 to 2025



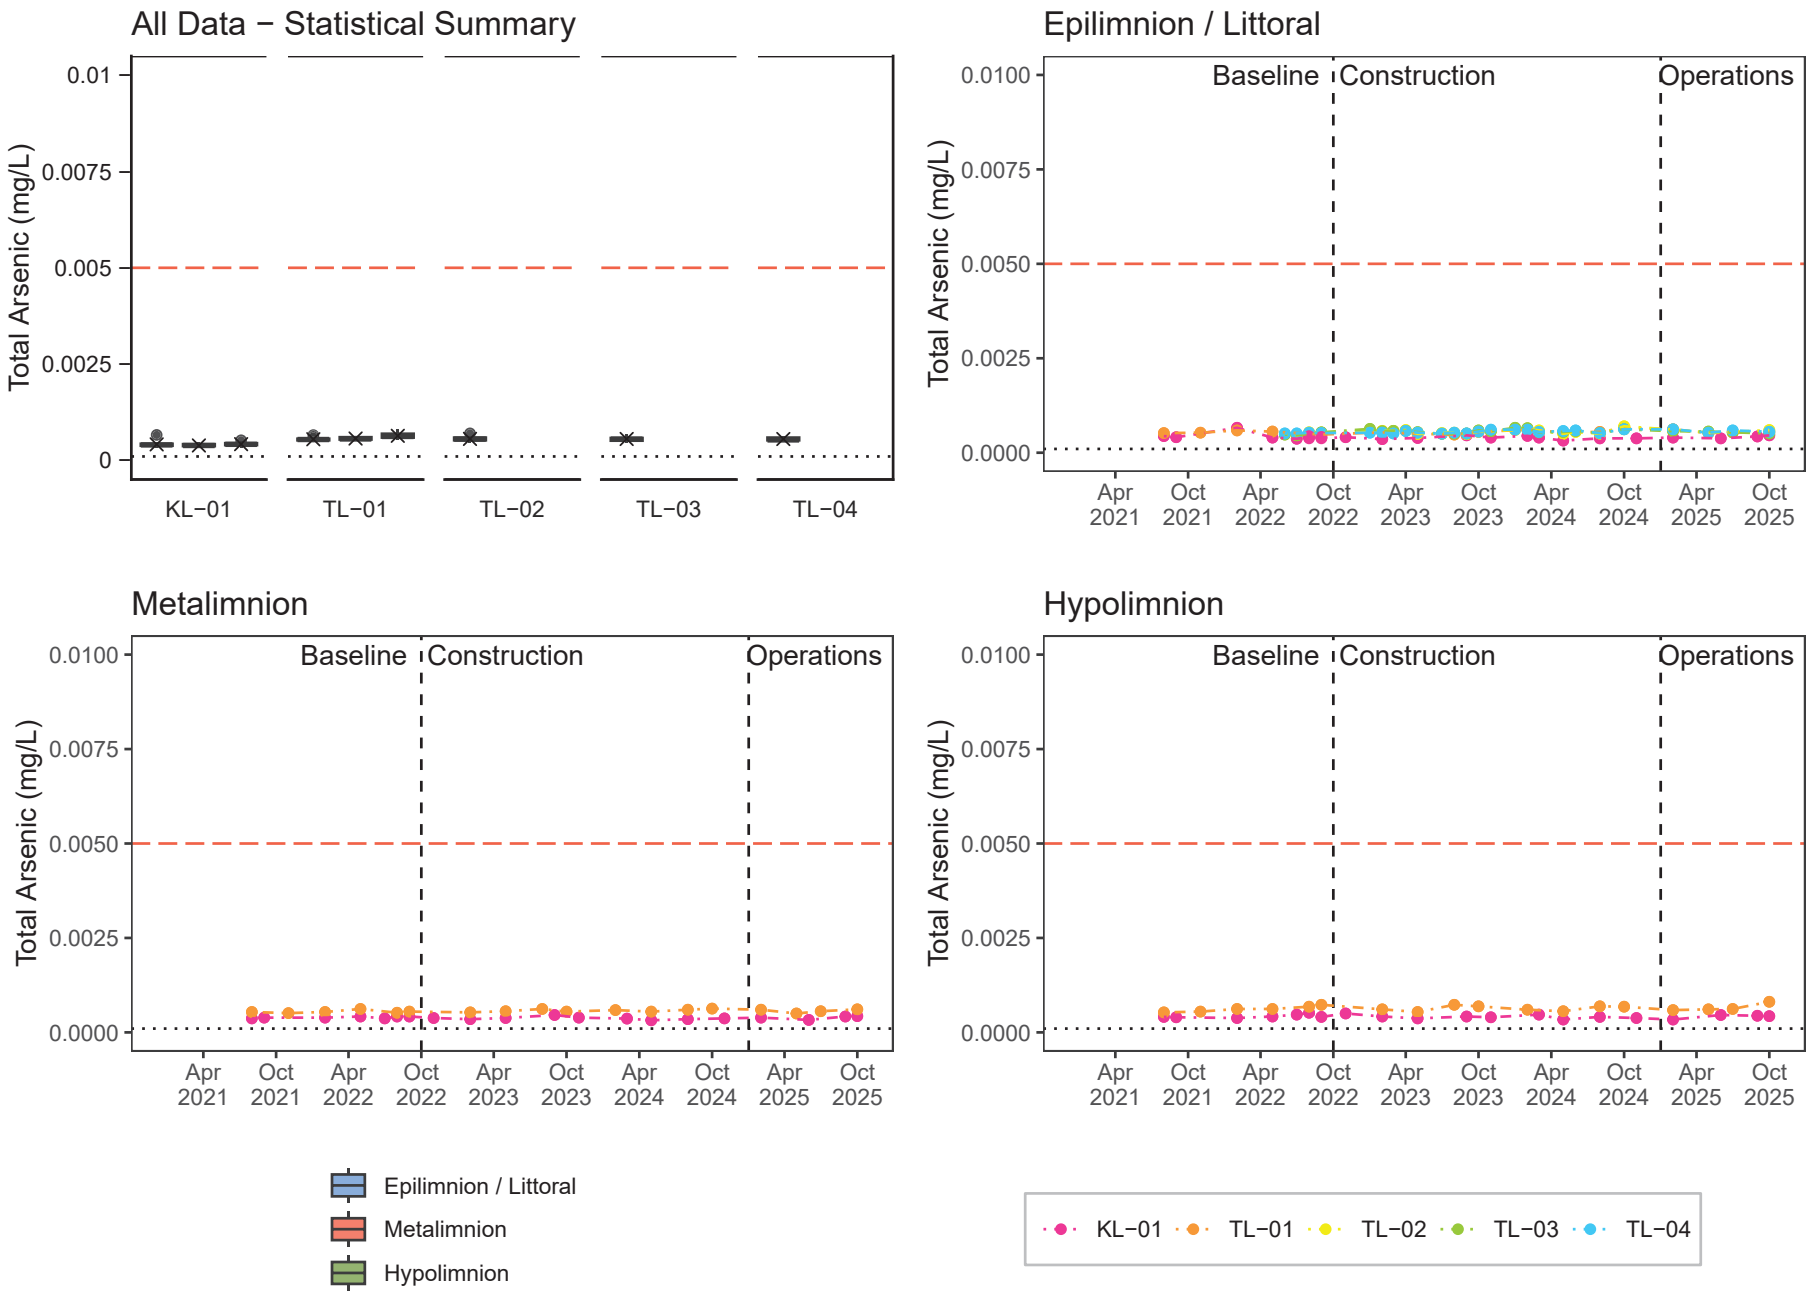
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.
Median BC WQG−AL long−term chronic guideline for total aluminum for Project lakes is 0.55 mg/L.

Figure A9−24: Total Aluminum in AEMP Monitored Lakes, 2021 to 2025



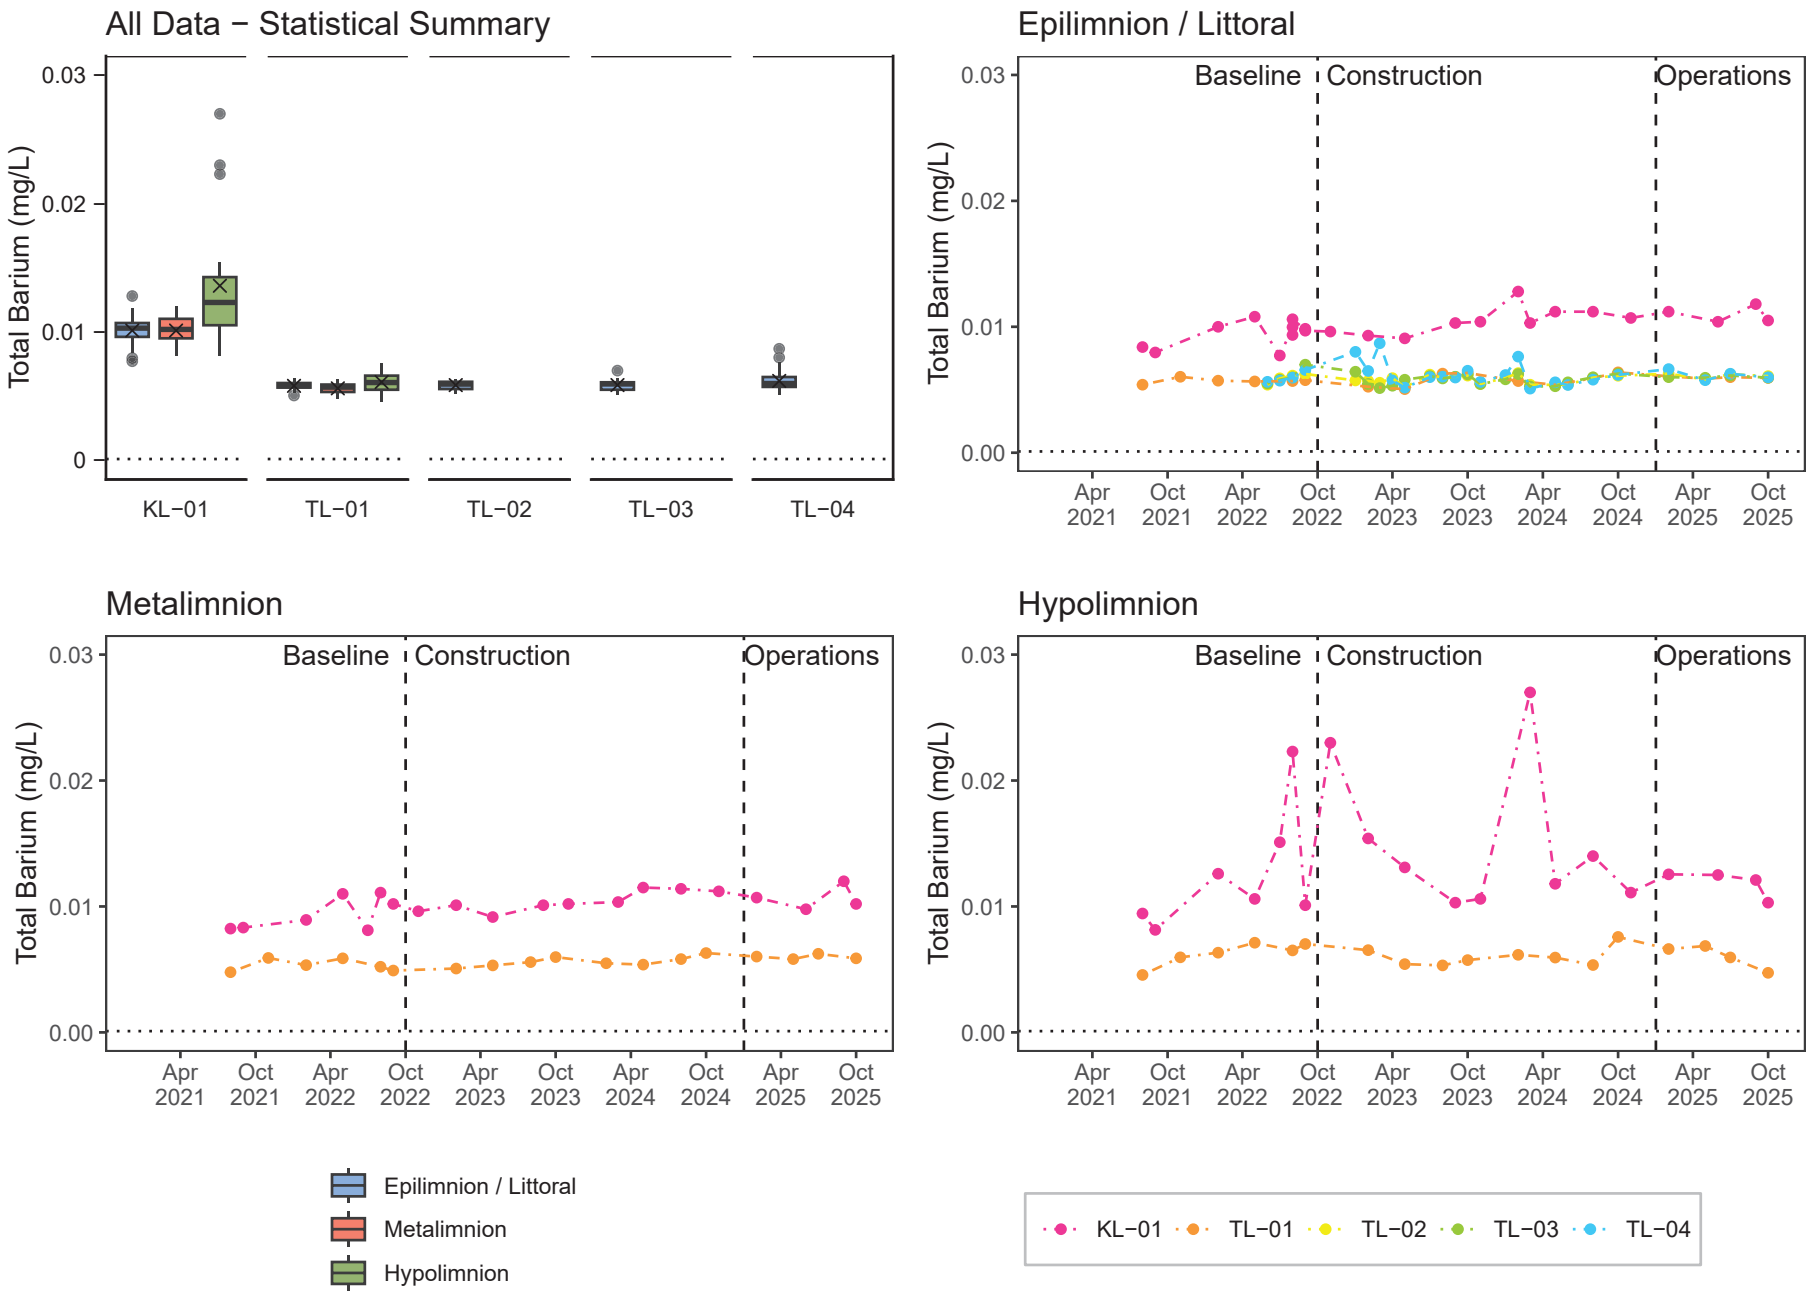
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.
BC WQG−AL long−term 30−day guideline for total antimony is 0.074 mg/L.

Figure A9−25: Total Antimony in AEMP Monitored Lakes, 2021 to 2025



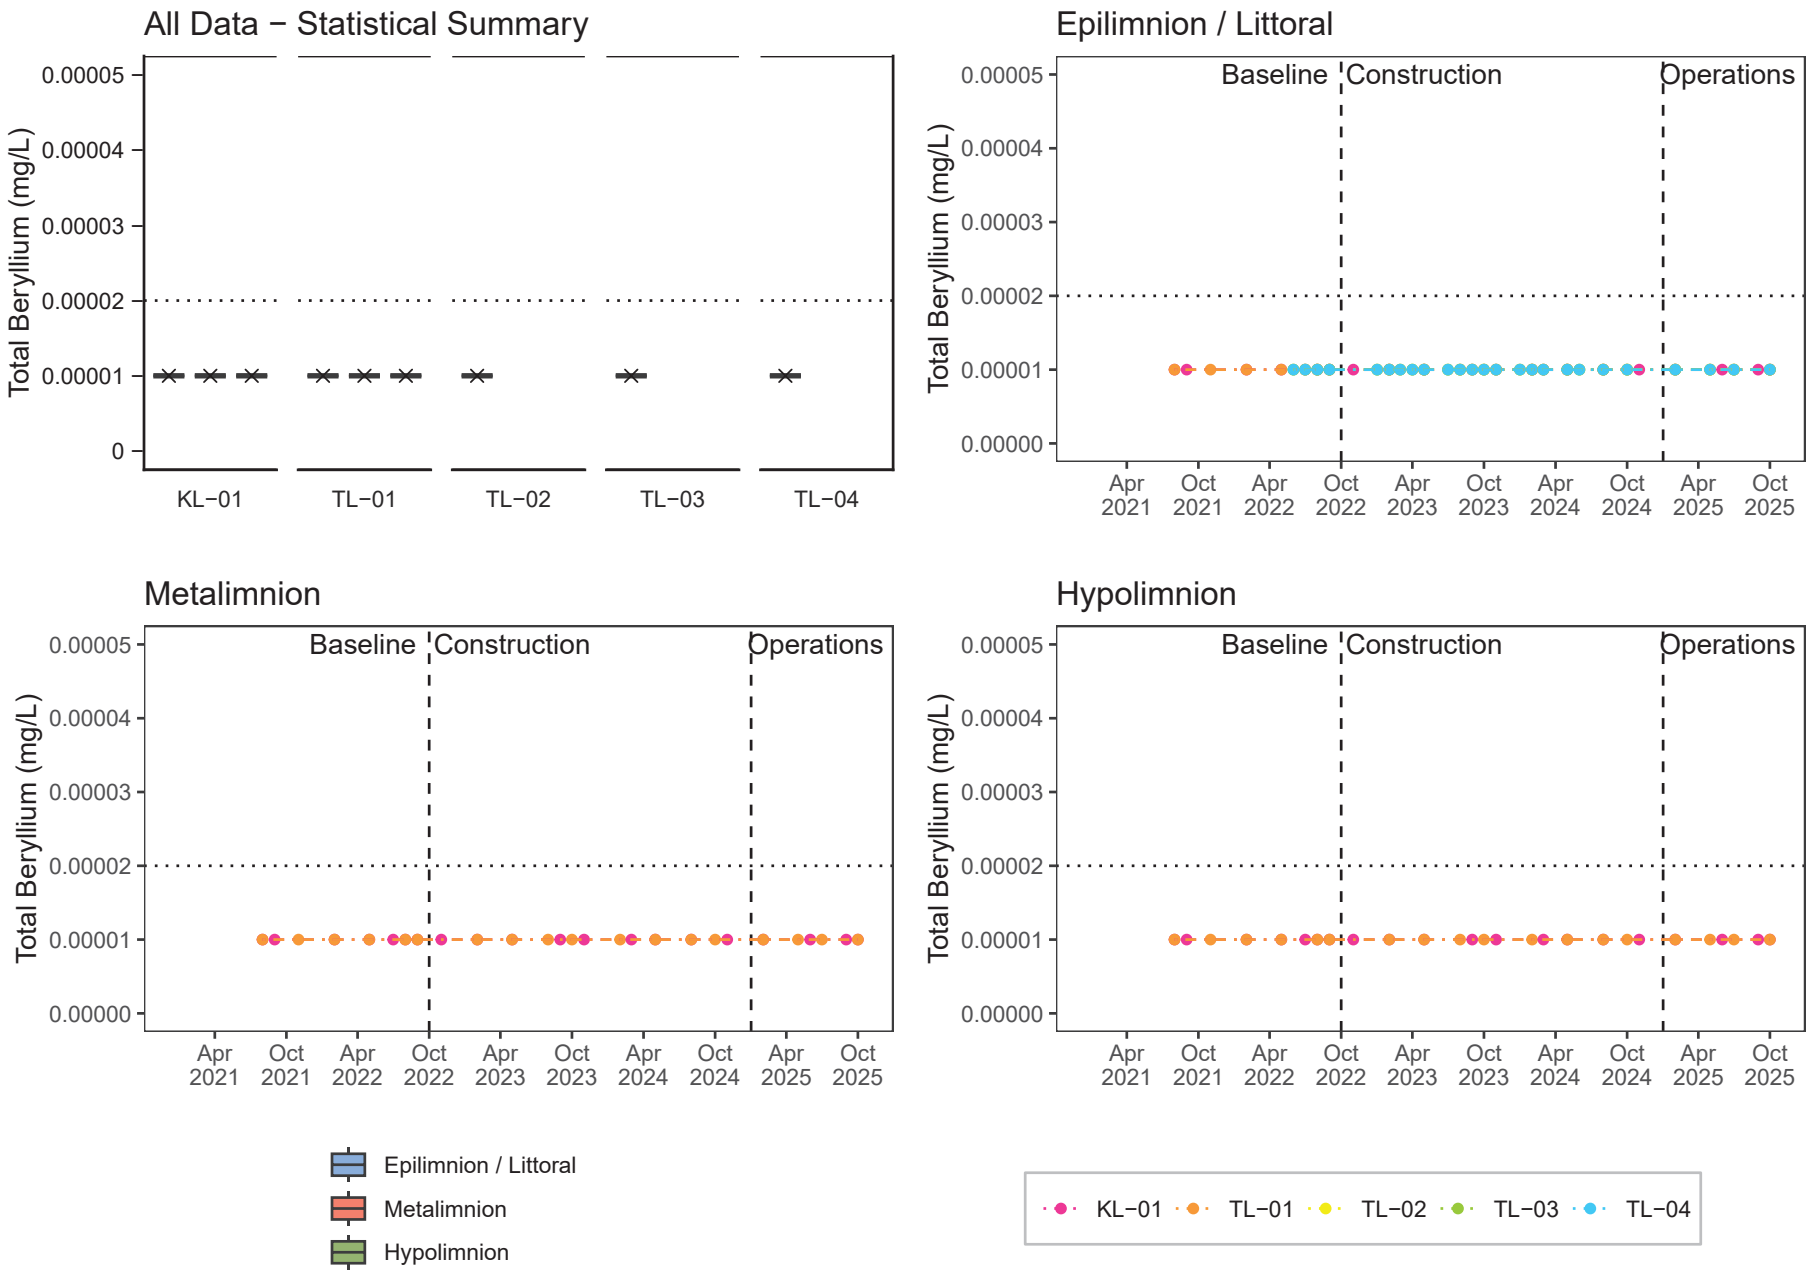
Notes: Dashed line indicates minimum detection limits.
BC WQG−AL long−term chronic guideline for total arsenic is 0.005 mg/L for a 30−day period.

Figure A9−26: Total Arsenic in AEMP Monitored Lakes, 2021 to 2025



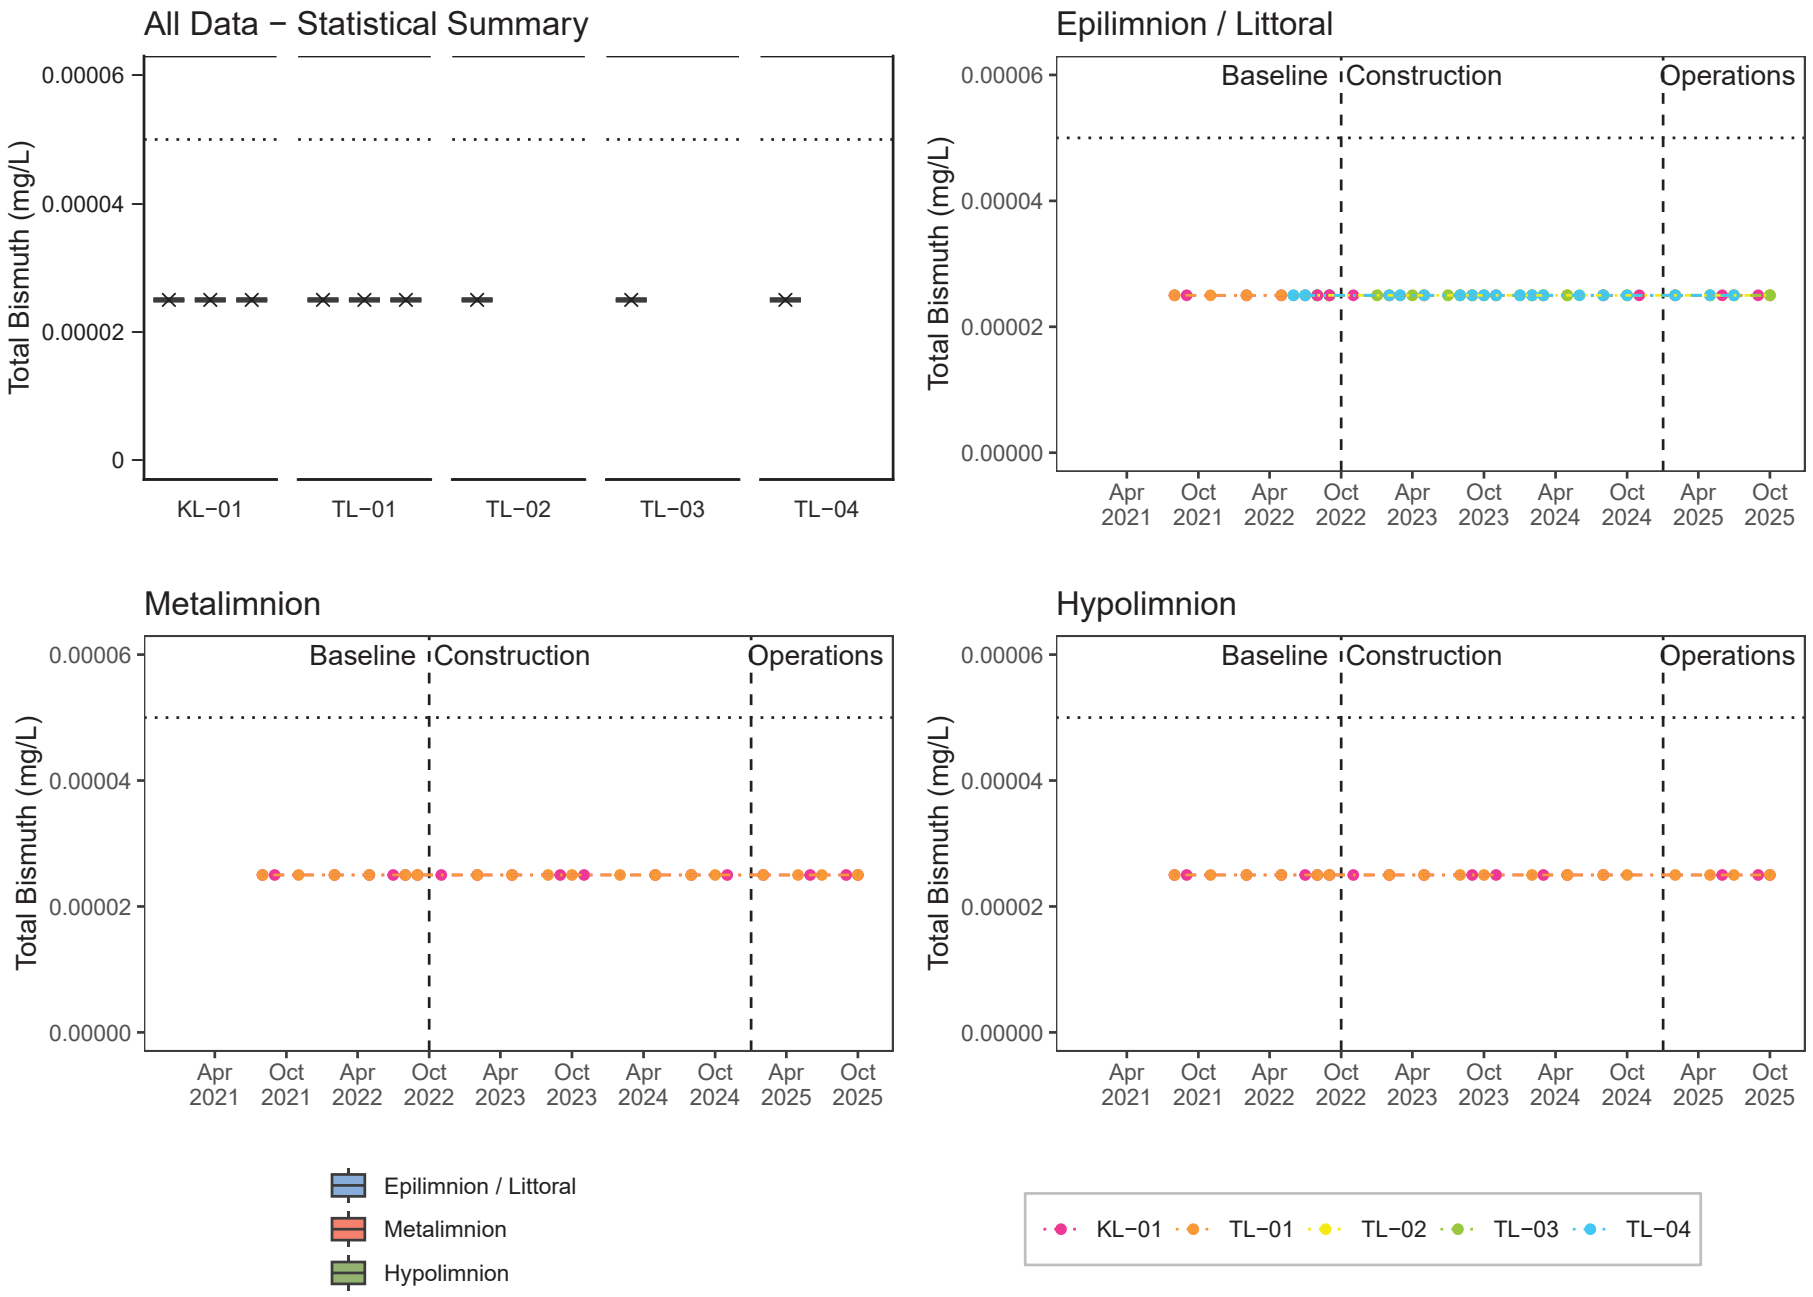
Notes: Dashed line indicates minimum detection limits.
BC WQG−AL working long−term chronic guideline for total barium is 1 mg/L.

Figure A9−27: Total Barium in AEMP Monitored Lakes, 2021 to 2025



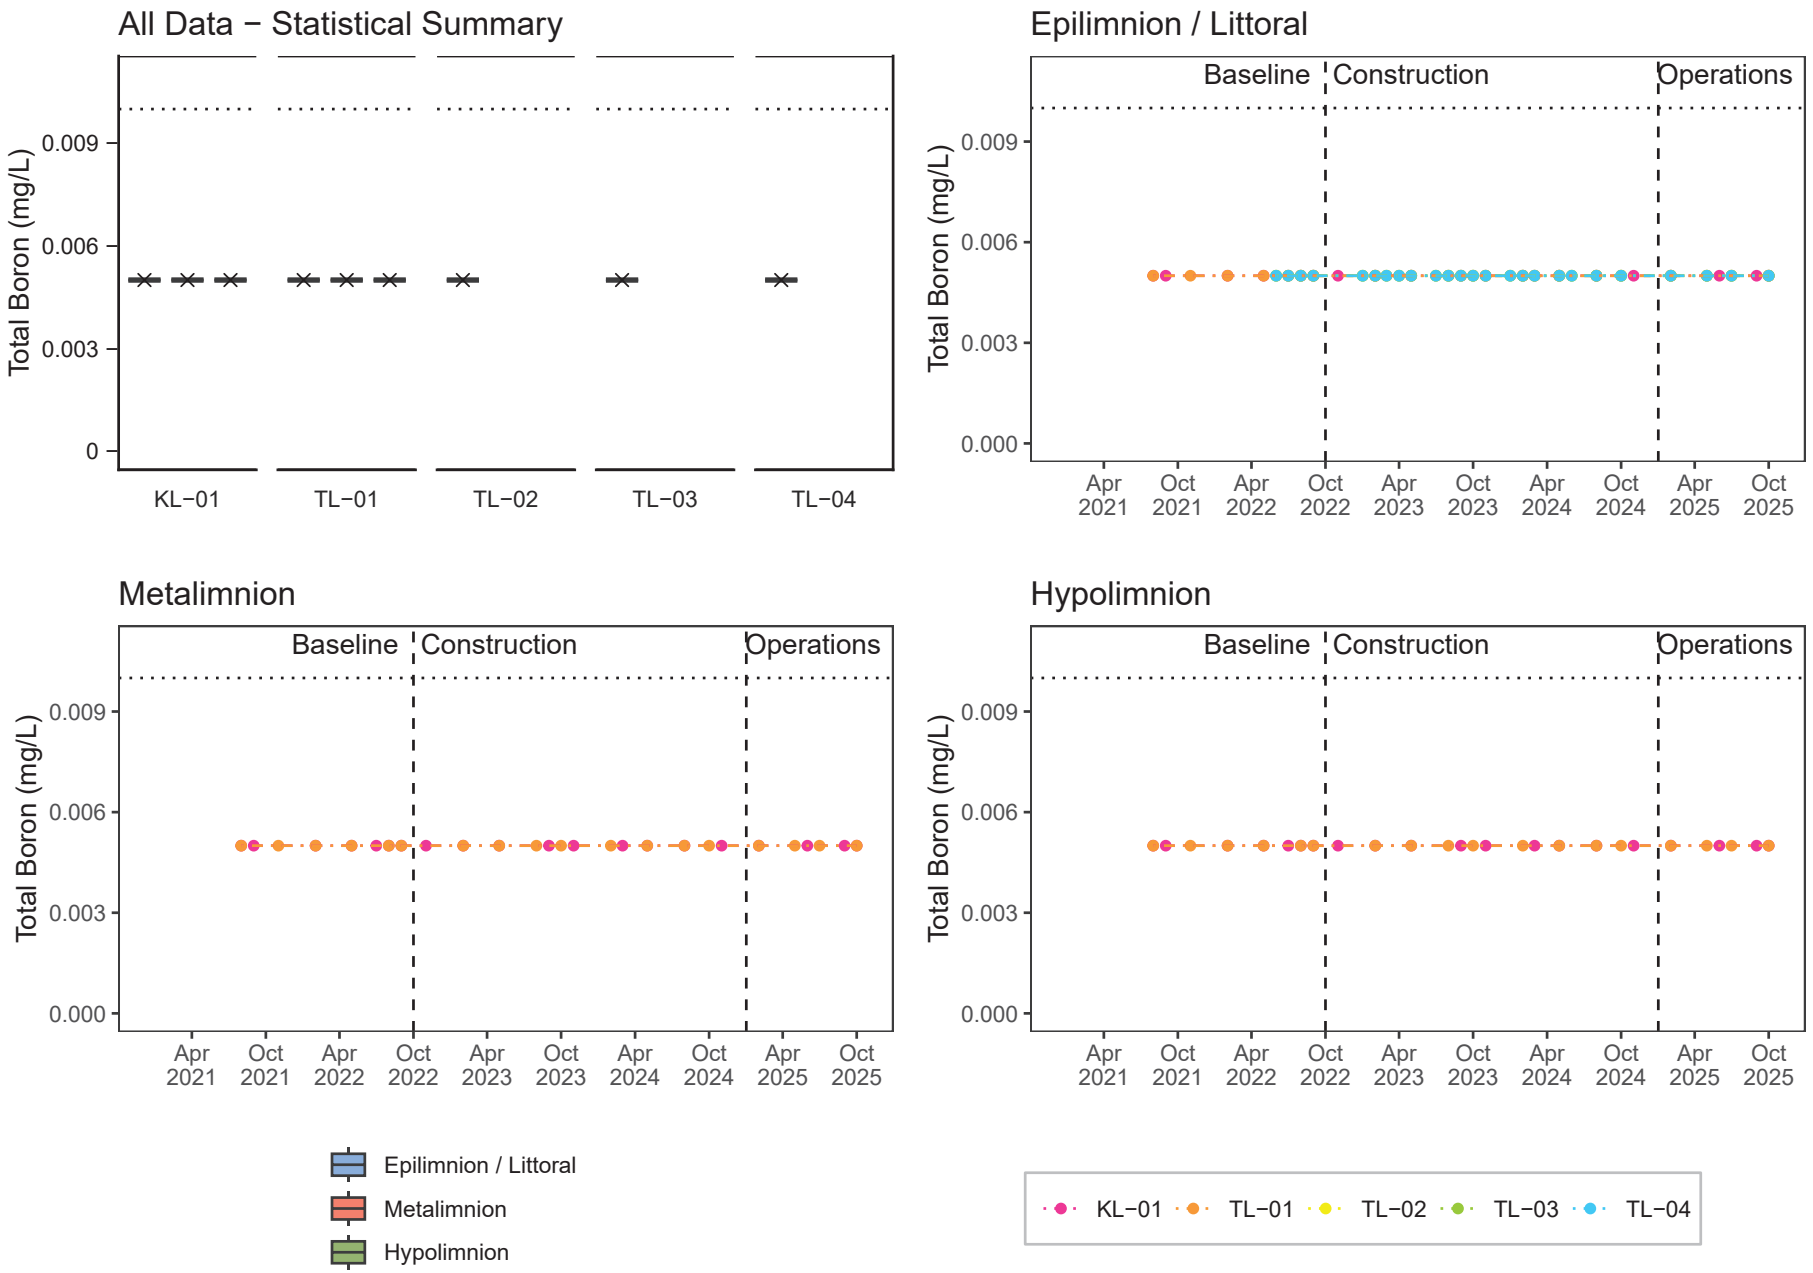
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.
BC WQG−AL working long−term chronic guideline for total beryllium is 0.00013 mg/L.

Figure A9−28: Total Beryllium in AEMP Monitored Lakes, 2021 to 2025



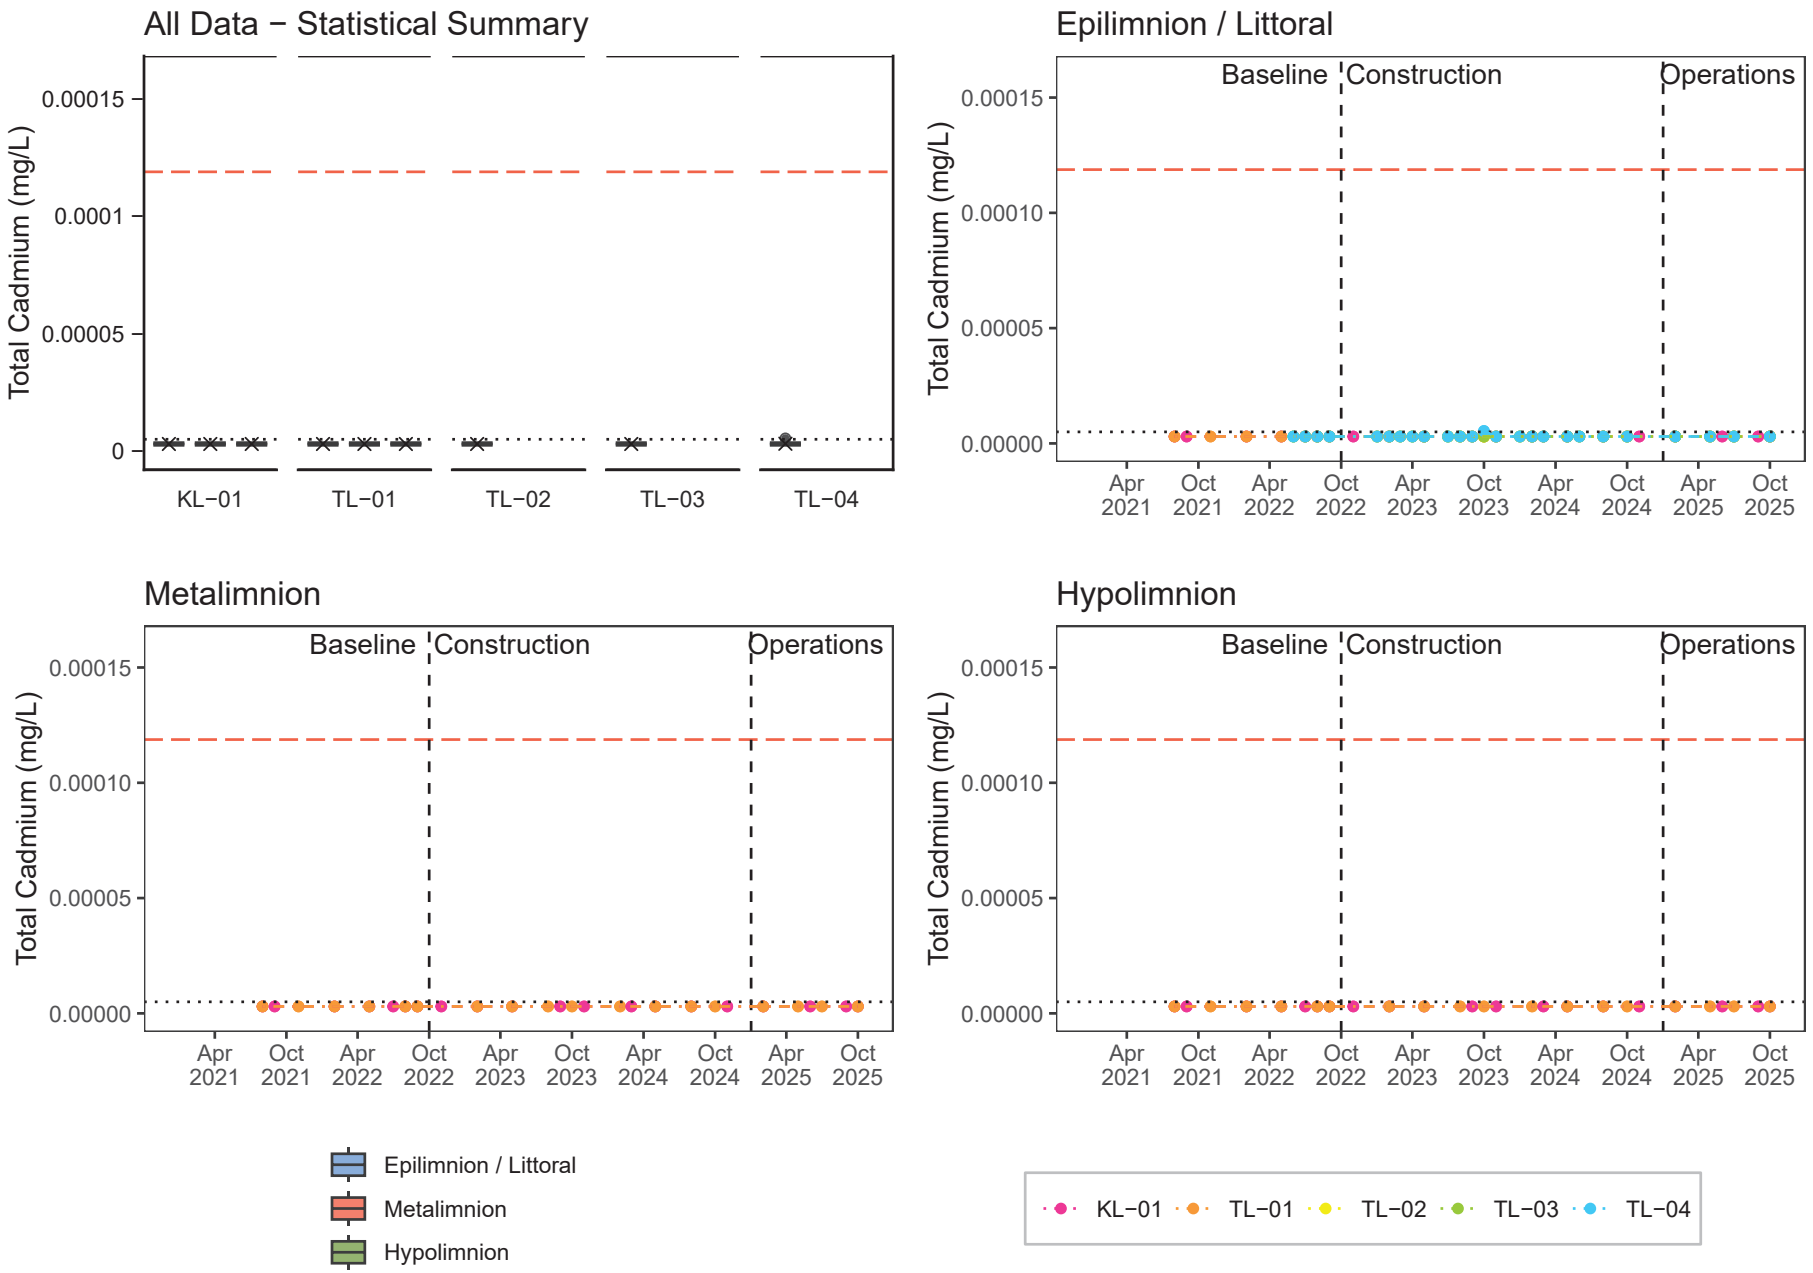
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−29: Total Bismuth in AEMP Monitored Lakes, 2021 to 2025



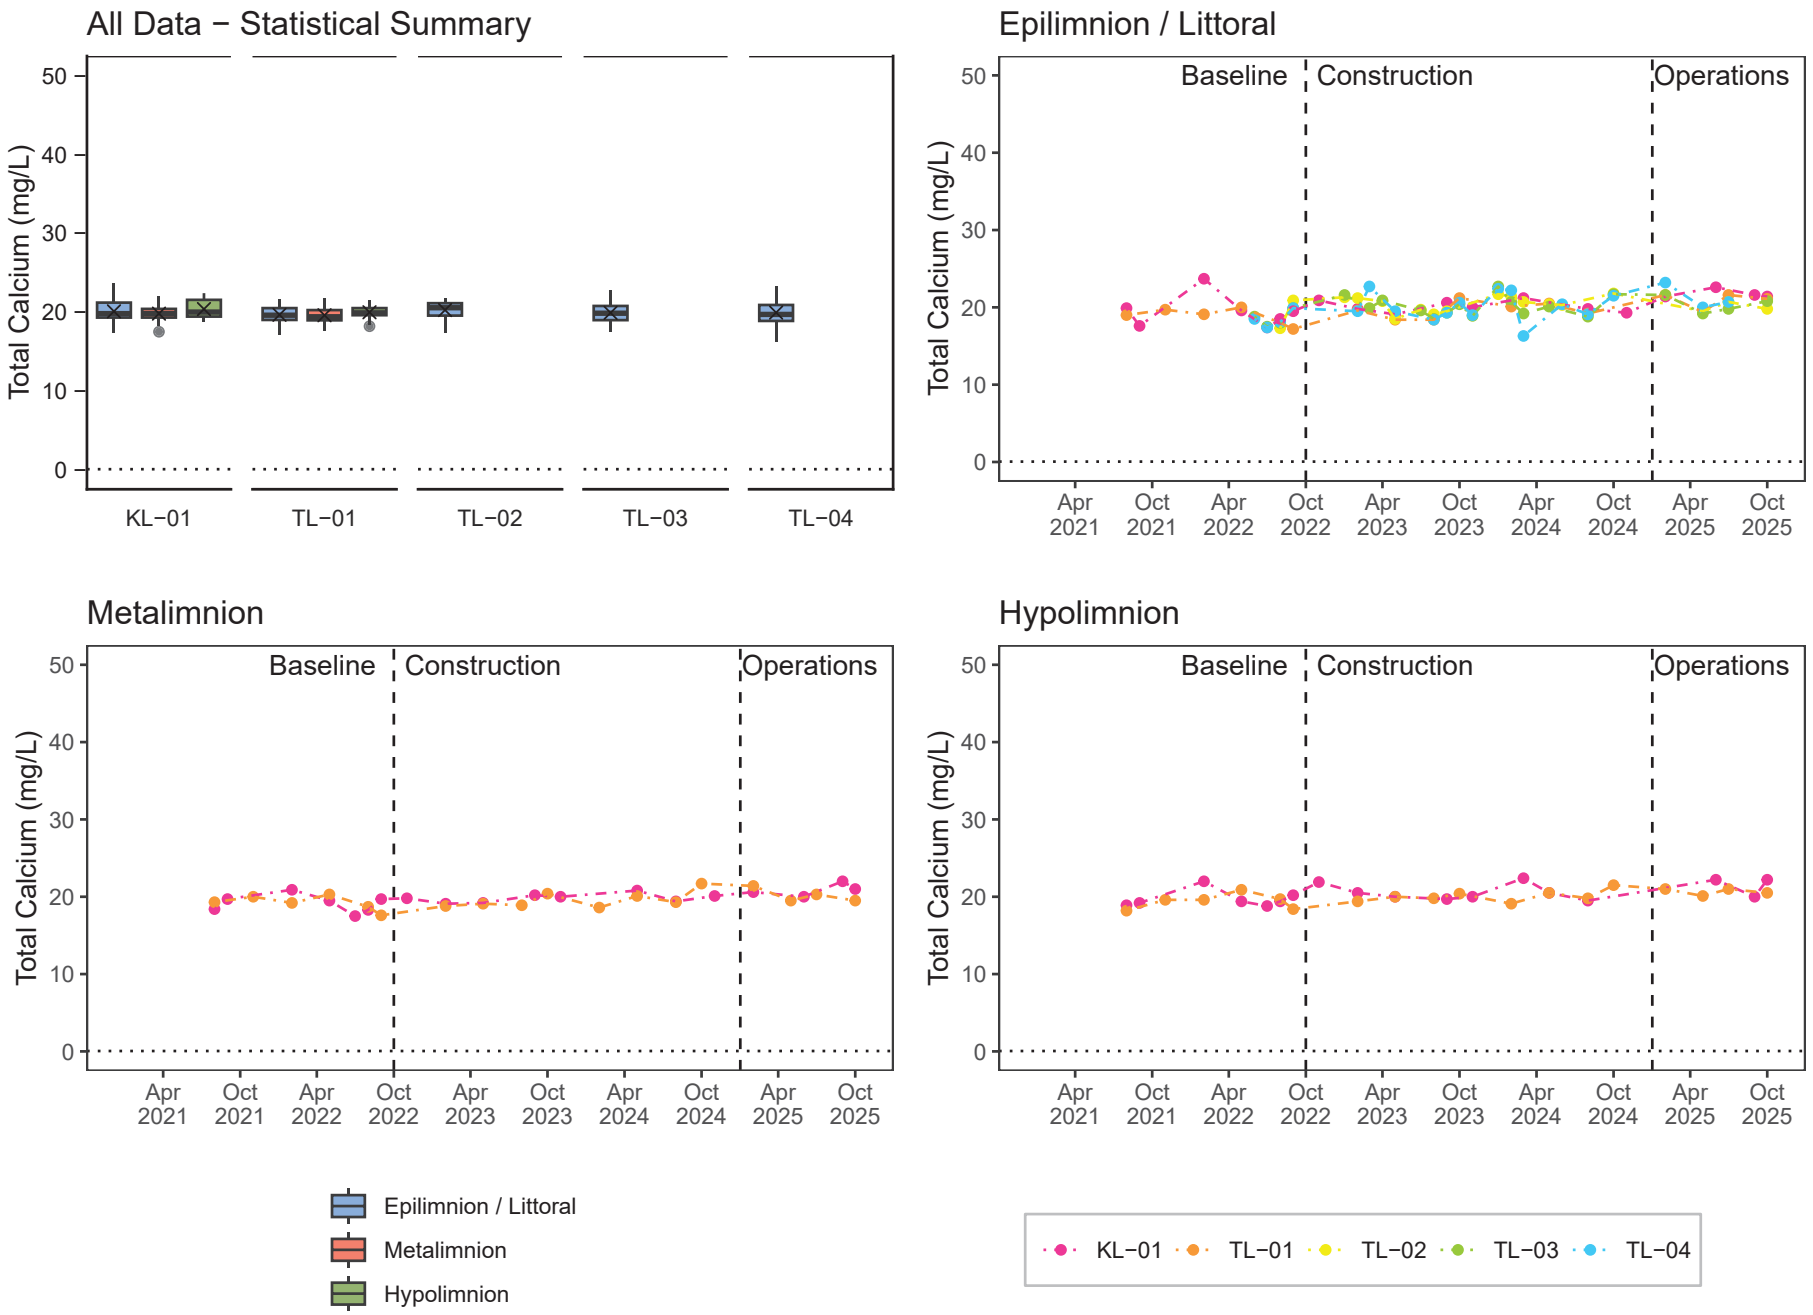
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.
BC WQG−AL working long−term chronic guideline for total boron is 1.2 mg/L.

Figure A9−30: Total Boron in AEMP Monitored Lakes, 2021 to 2025



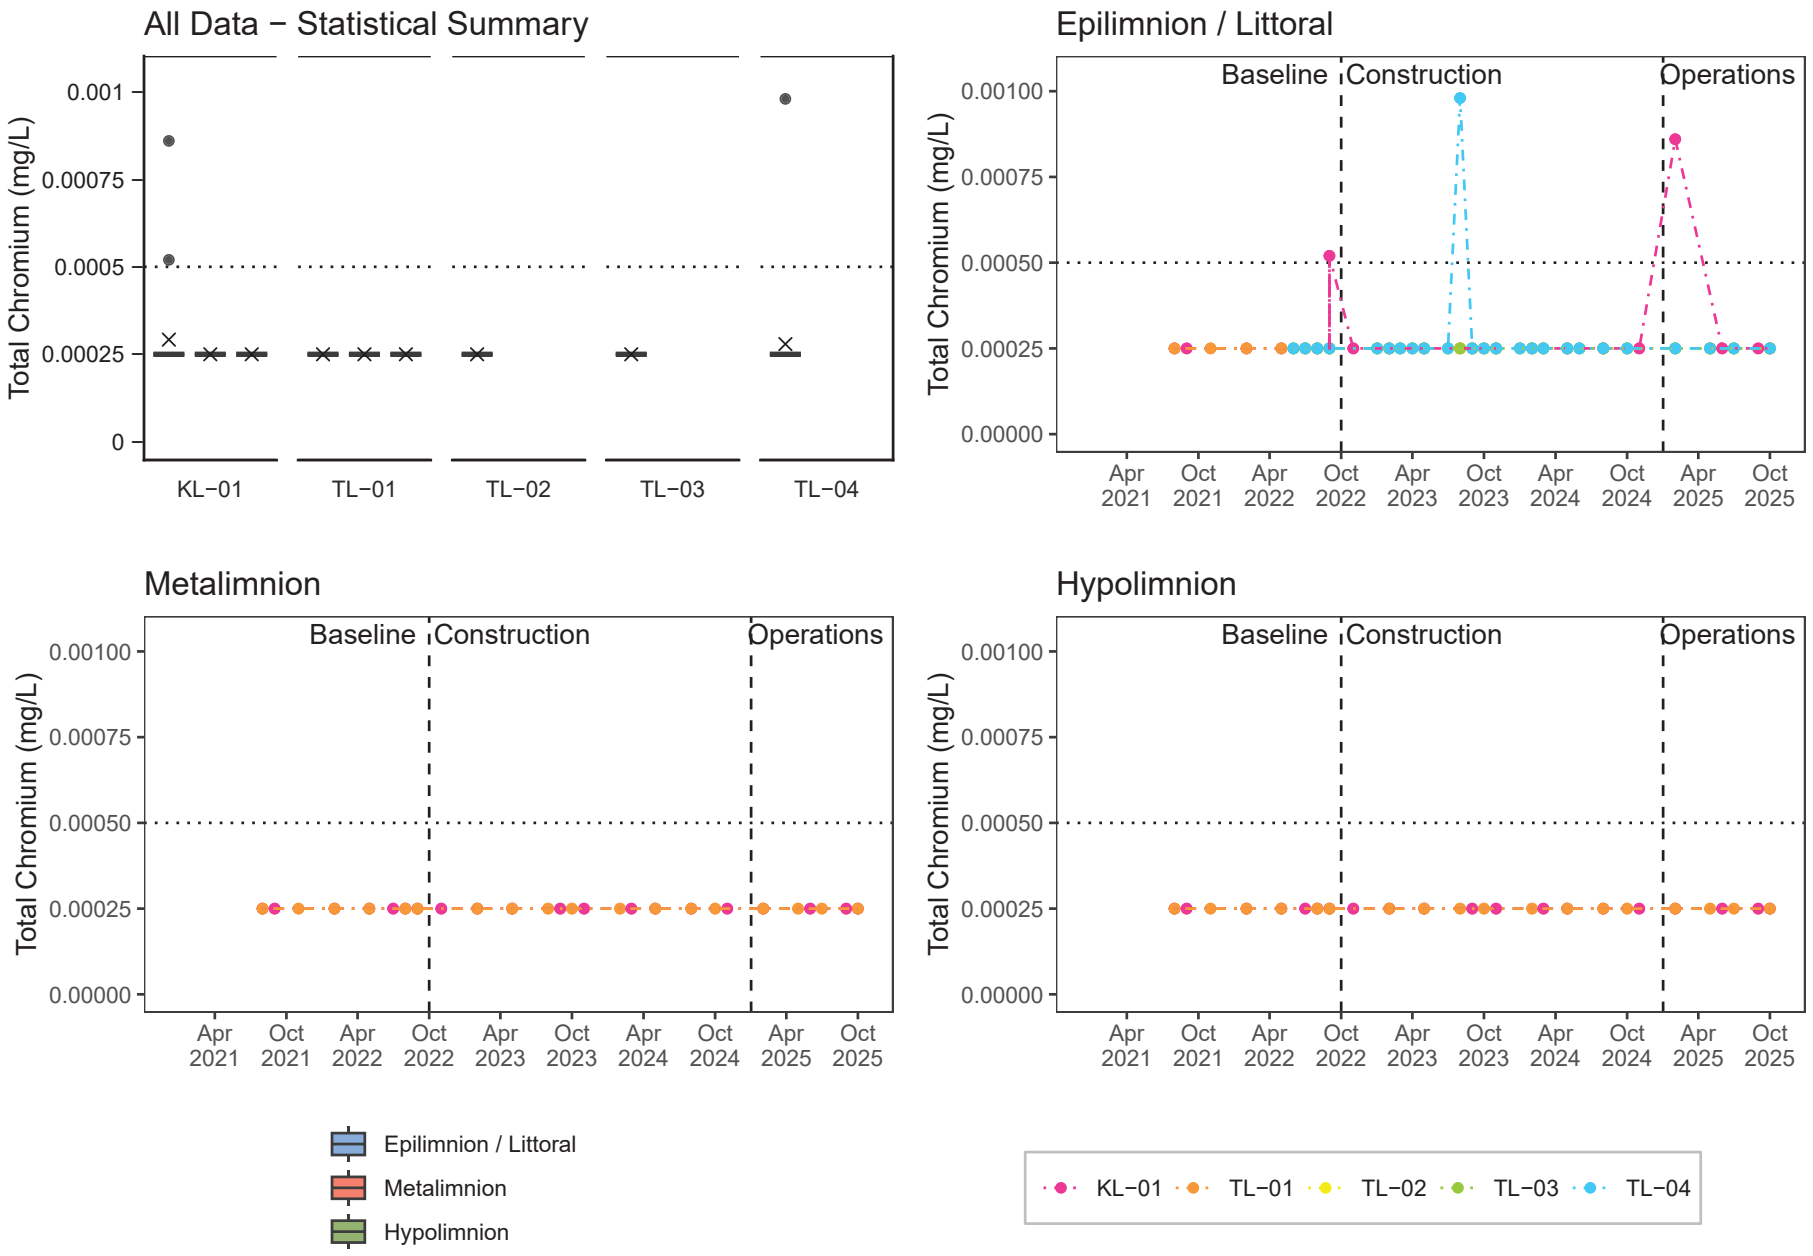
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.
Median CCME WQG−AL long−term chronic guideline for total cadmium for Project lakes is 0.00012 mg/L.

Figure A9−31: Total Cadmium in AEMP Monitored Lakes, 2021 to 2025



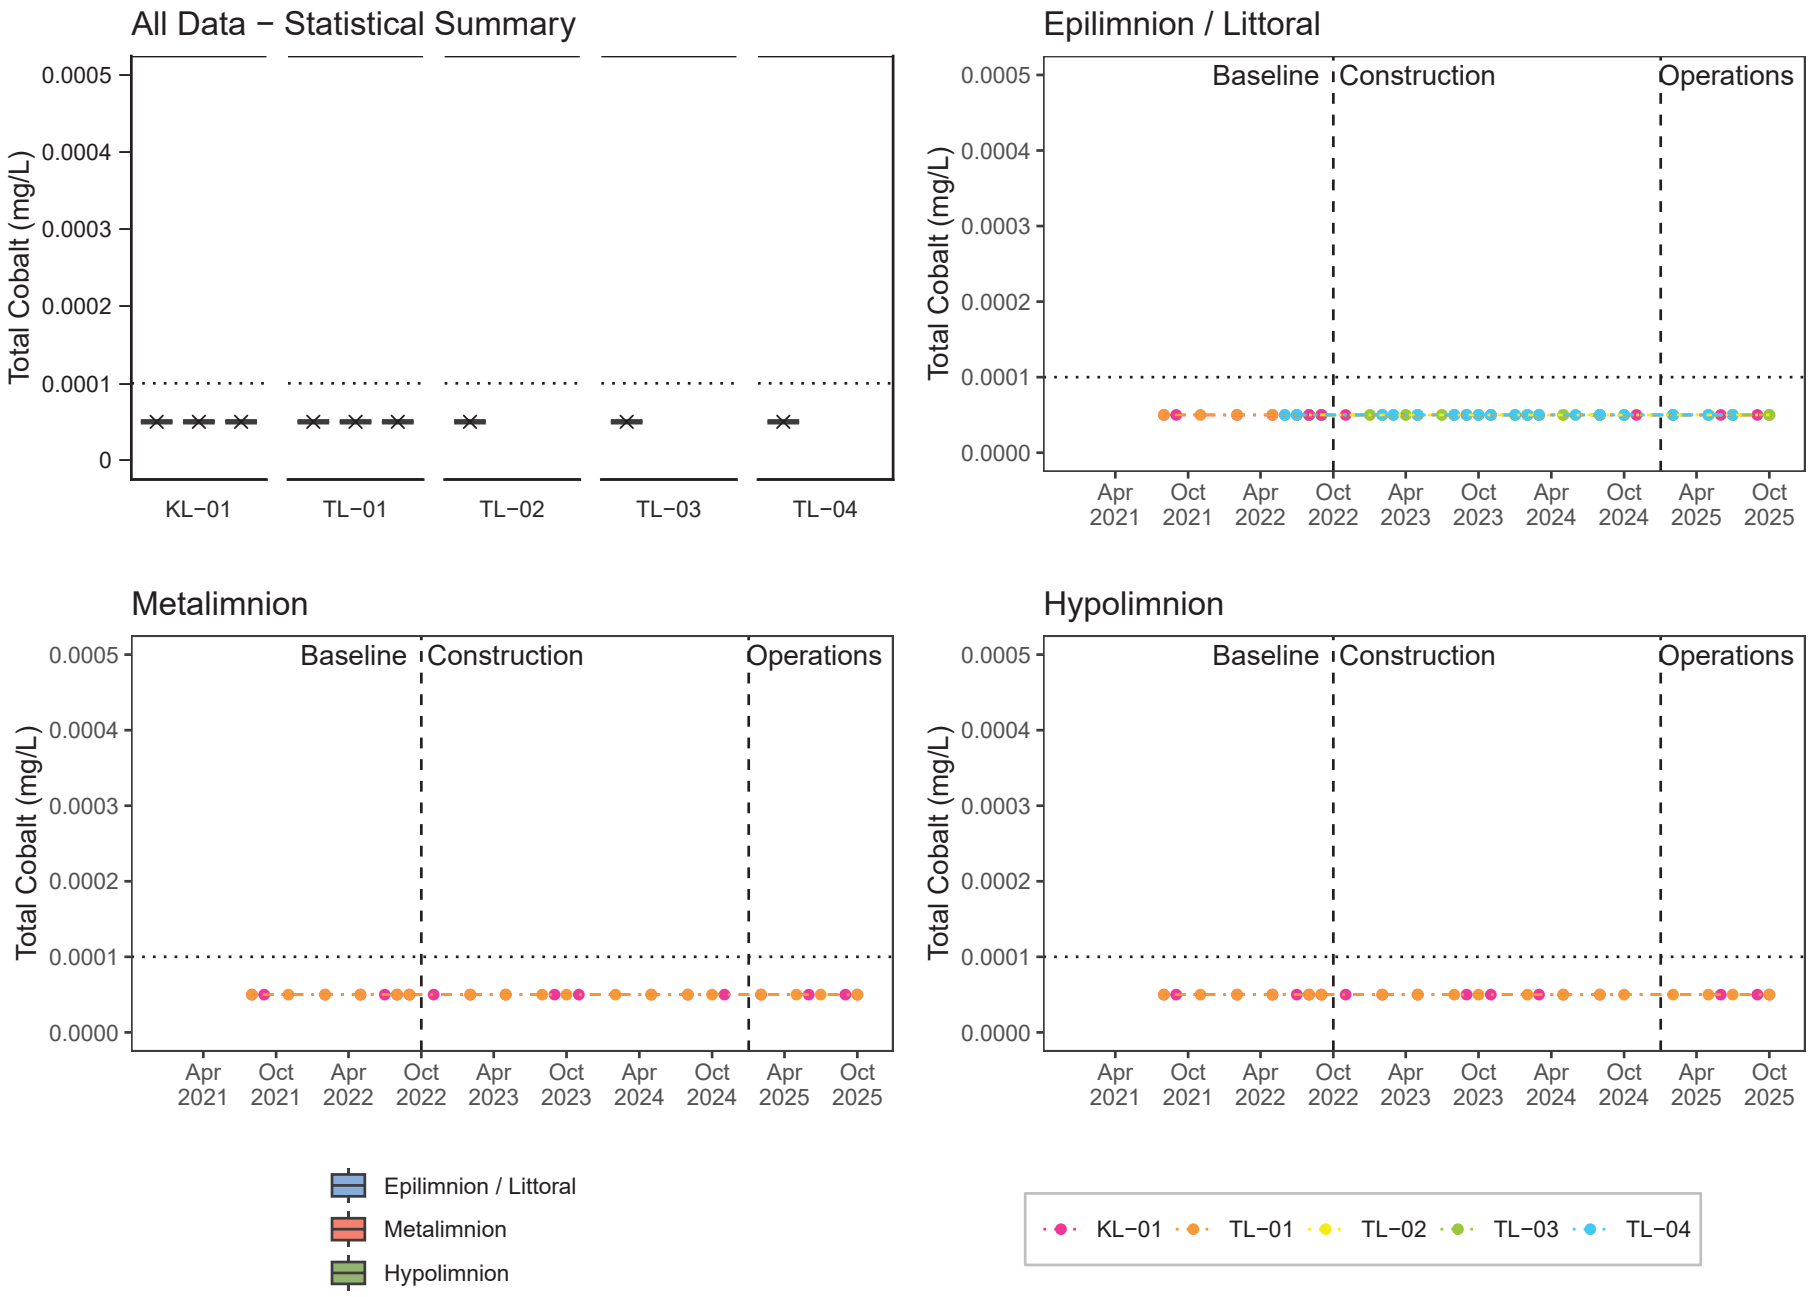
Notes: Dashed line indicates minimum detection limits.

Figure A9−32: Total Calcium in AEMP Monitored Lakes, 2021 to 2025



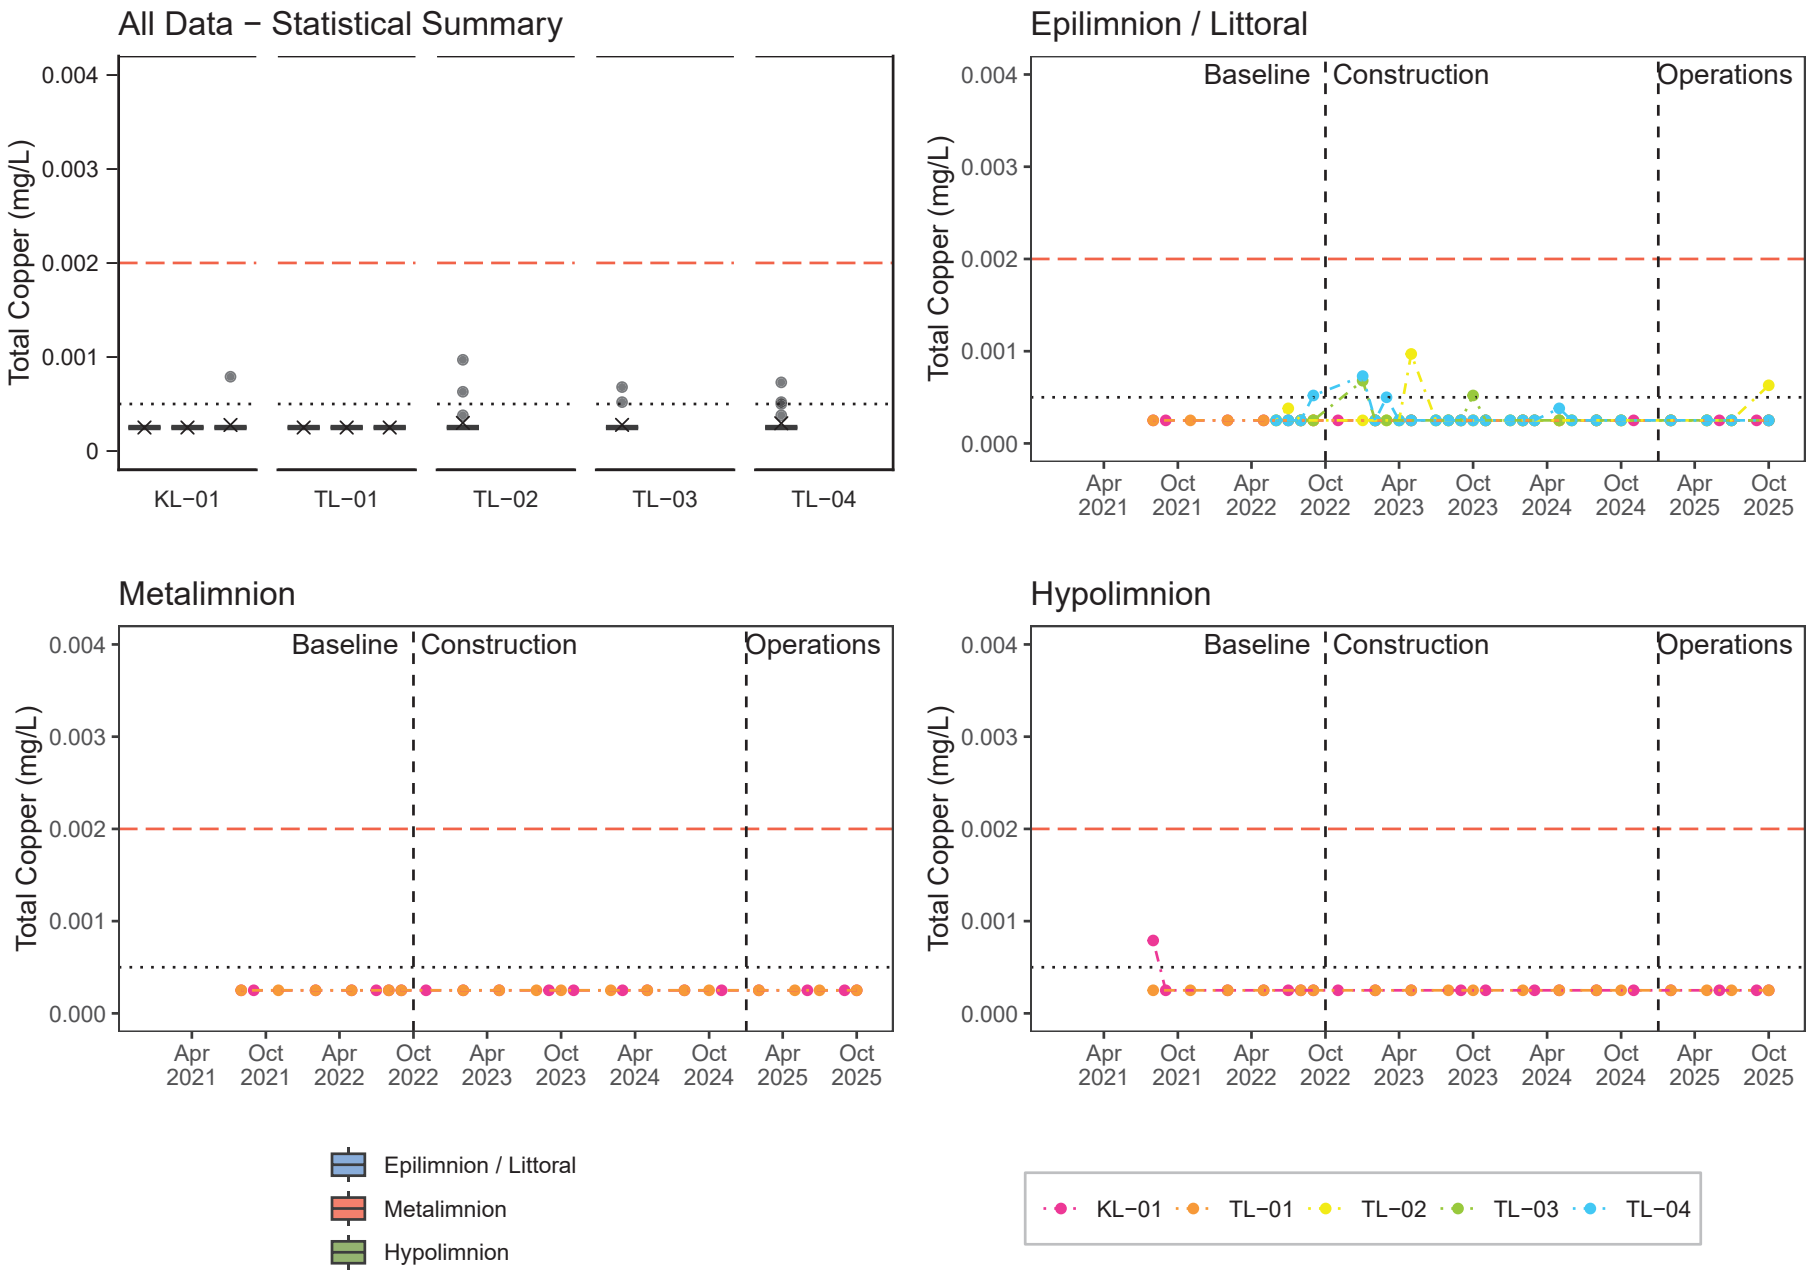
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.
BC WQG−AL long−term 30−day guideline for total chromium[VI] is 0.0025 mg/L.
BC WQG−AL long−term 30−day guideline for total chromium[III] is 0.0089 mg/L.

Figure A9−33: Total Chromium in AEMP Monitored Lakes, 2021 to 2025



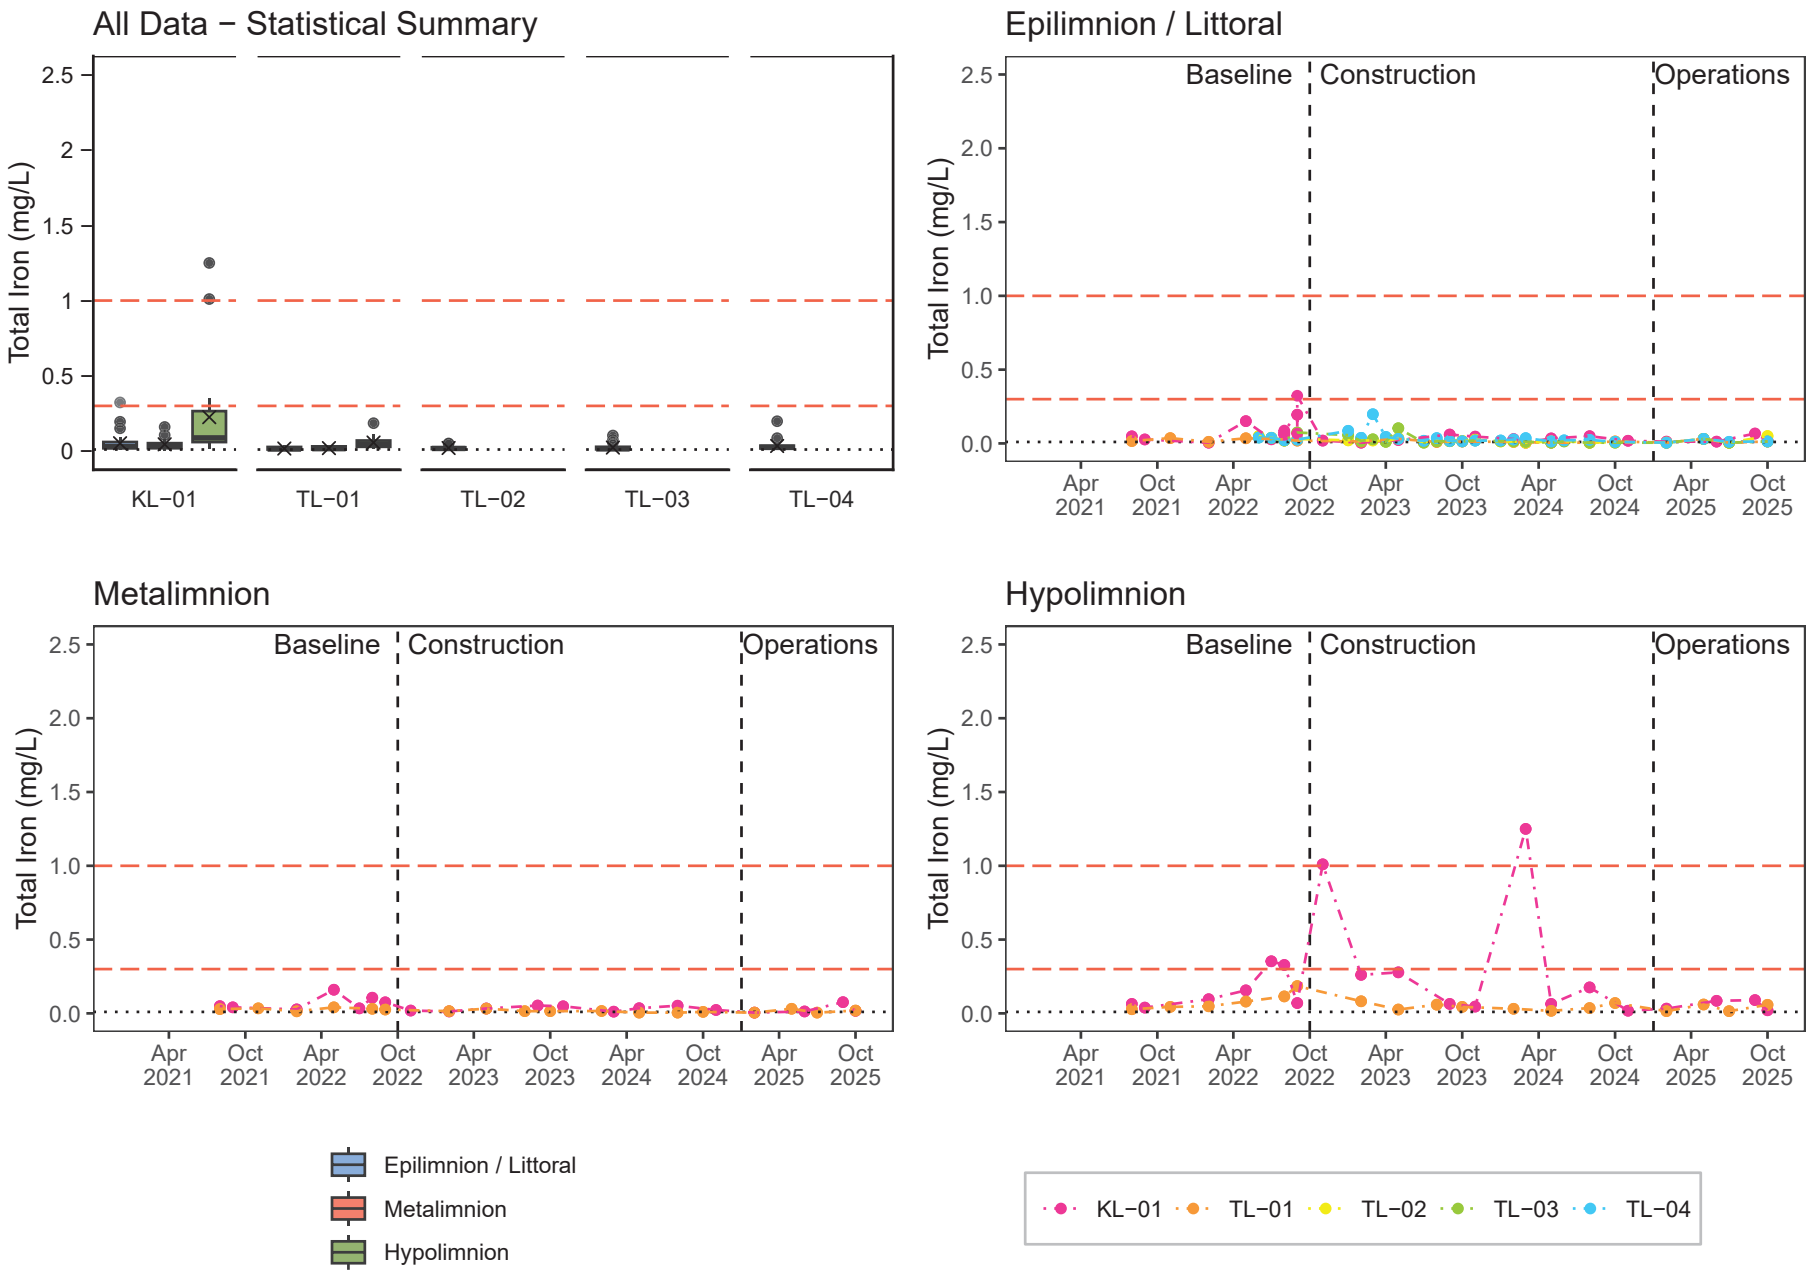
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−34: Total Cobalt in AEMP Monitored Lakes, 2021 to 2025



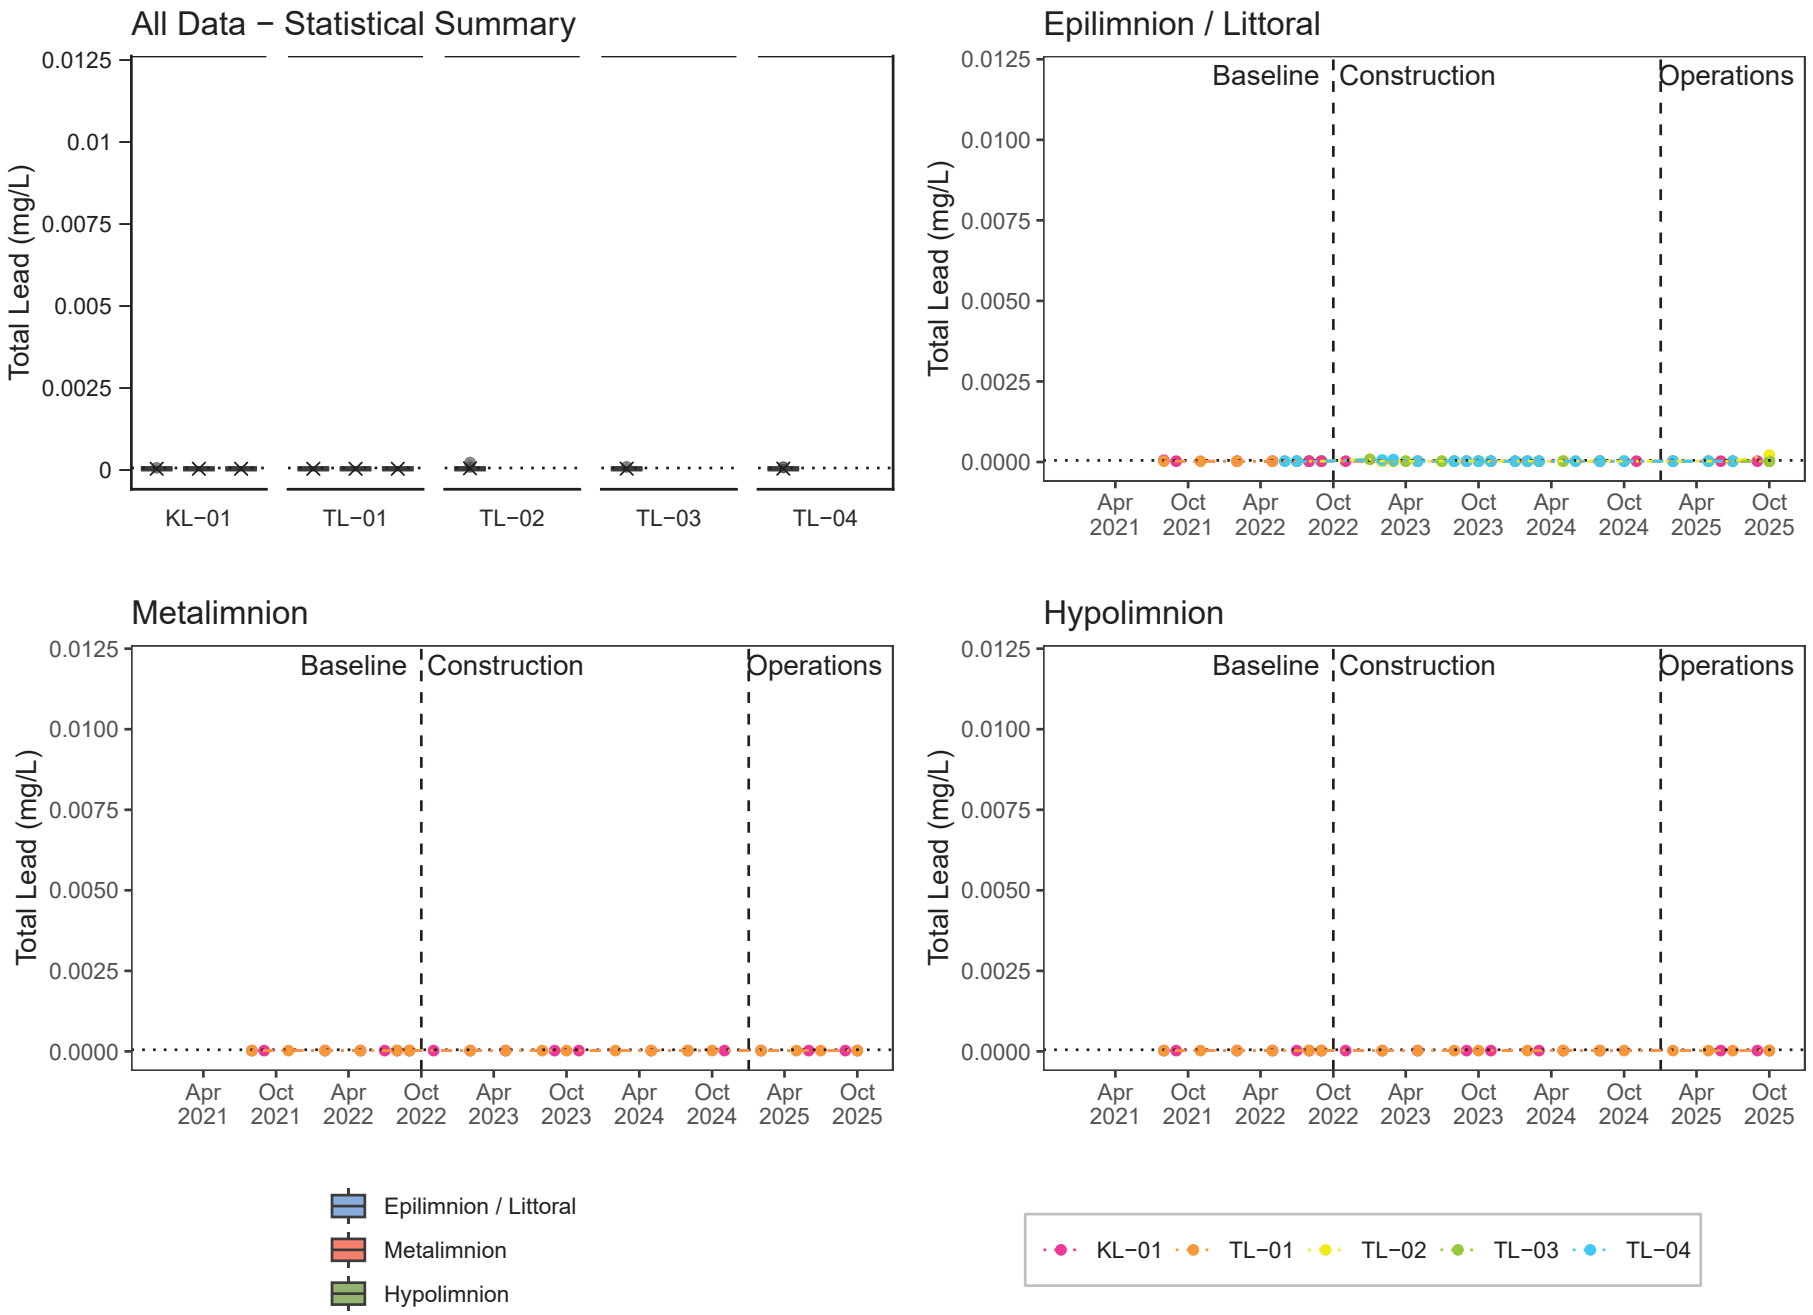
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.
Median CCME WQG−AL long−term chronic guideline for total copper for Project lakes is 0.002 mg/L.

Figure A9−35: Total Copper in AEMP Monitored Lakes, 2021 to 2025



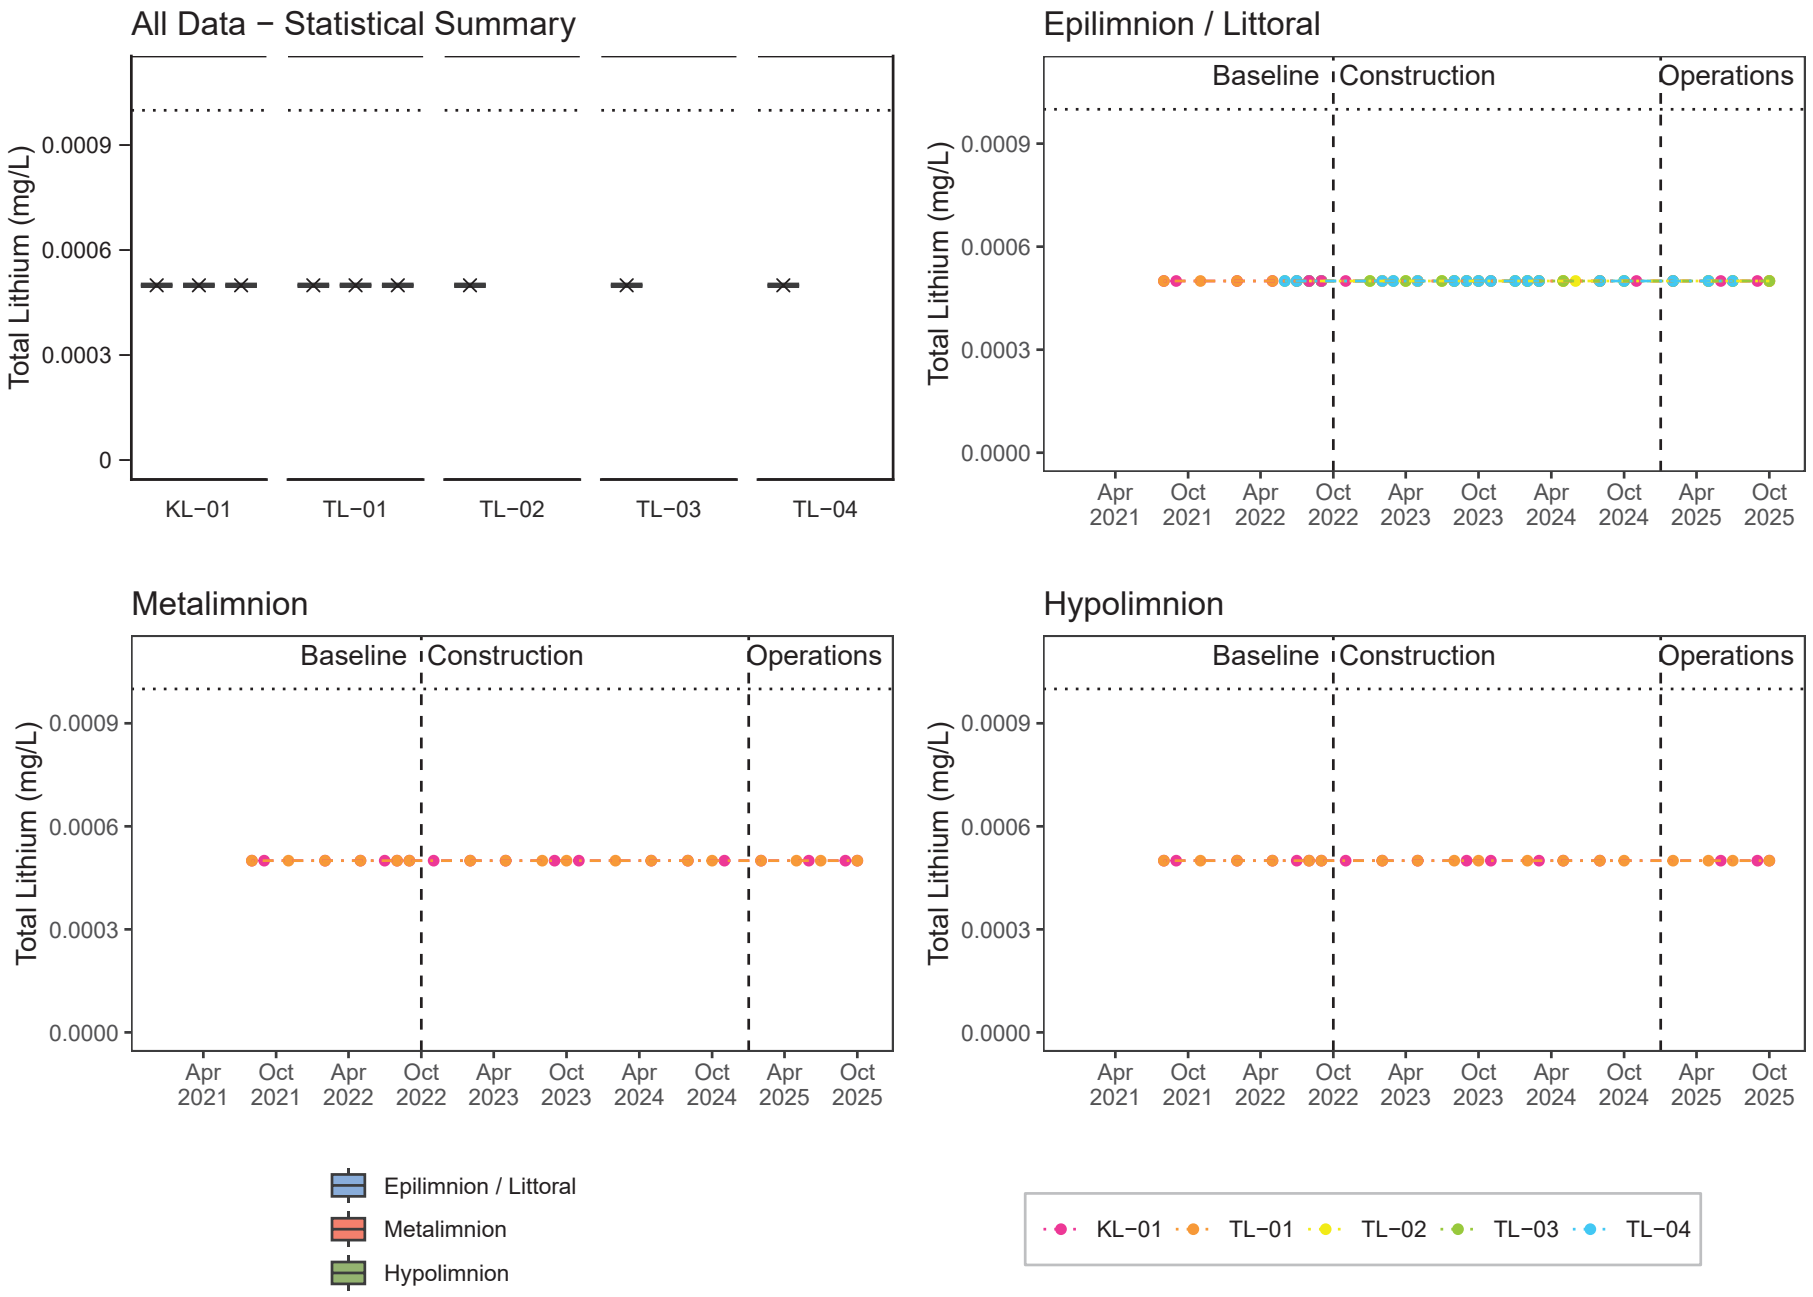
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.
BC WQG−AL short−term maxium guideline for total iron is 1.0 mg/L.

Figure A9−36: Total Iron in AEMP Monitored Lakes, 2021 to 2025



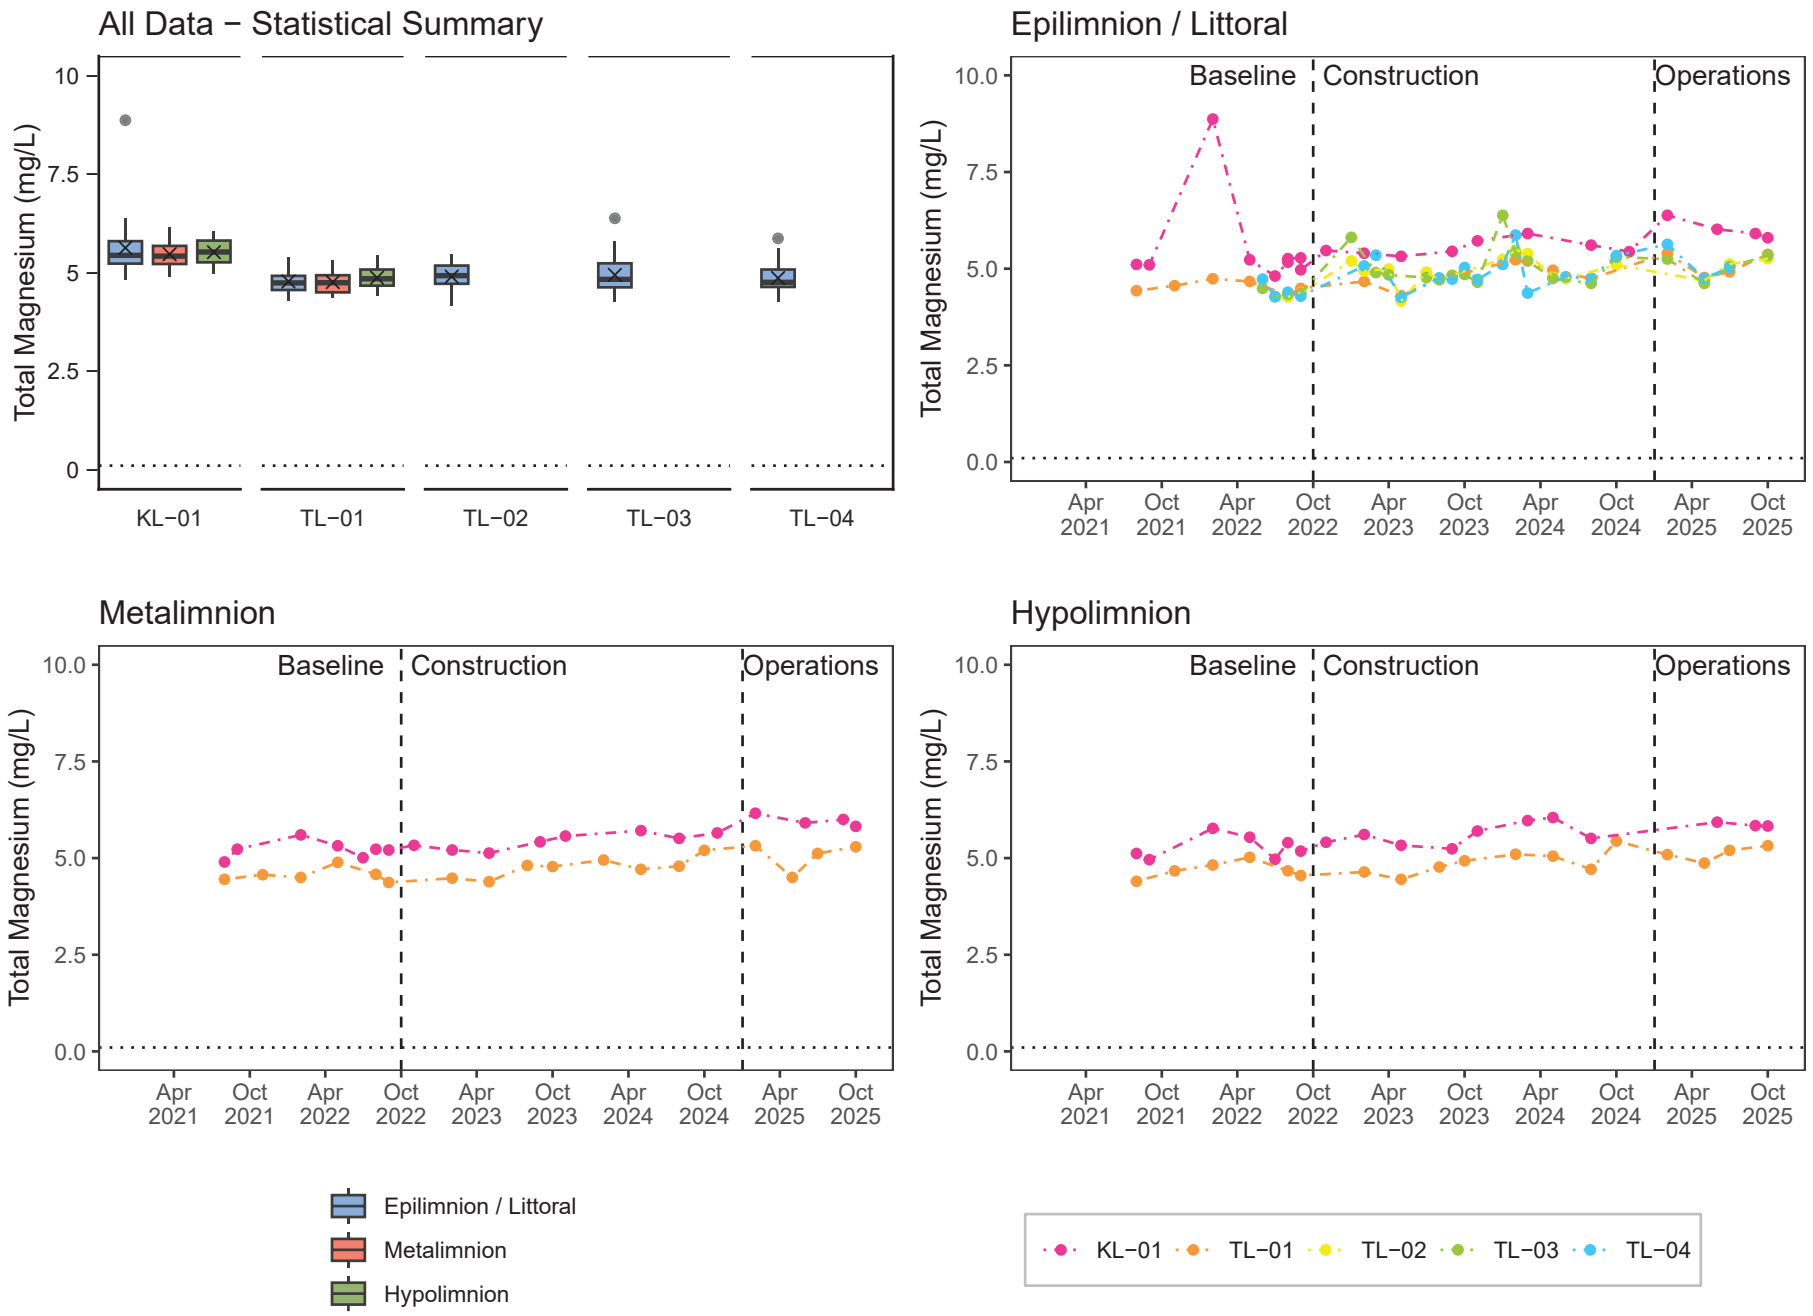
Notes: Dashed line indicates minimum detection limits.

Figure A9−37: Total Lead in AEMP Monitored Lakes, 2021 to 2025



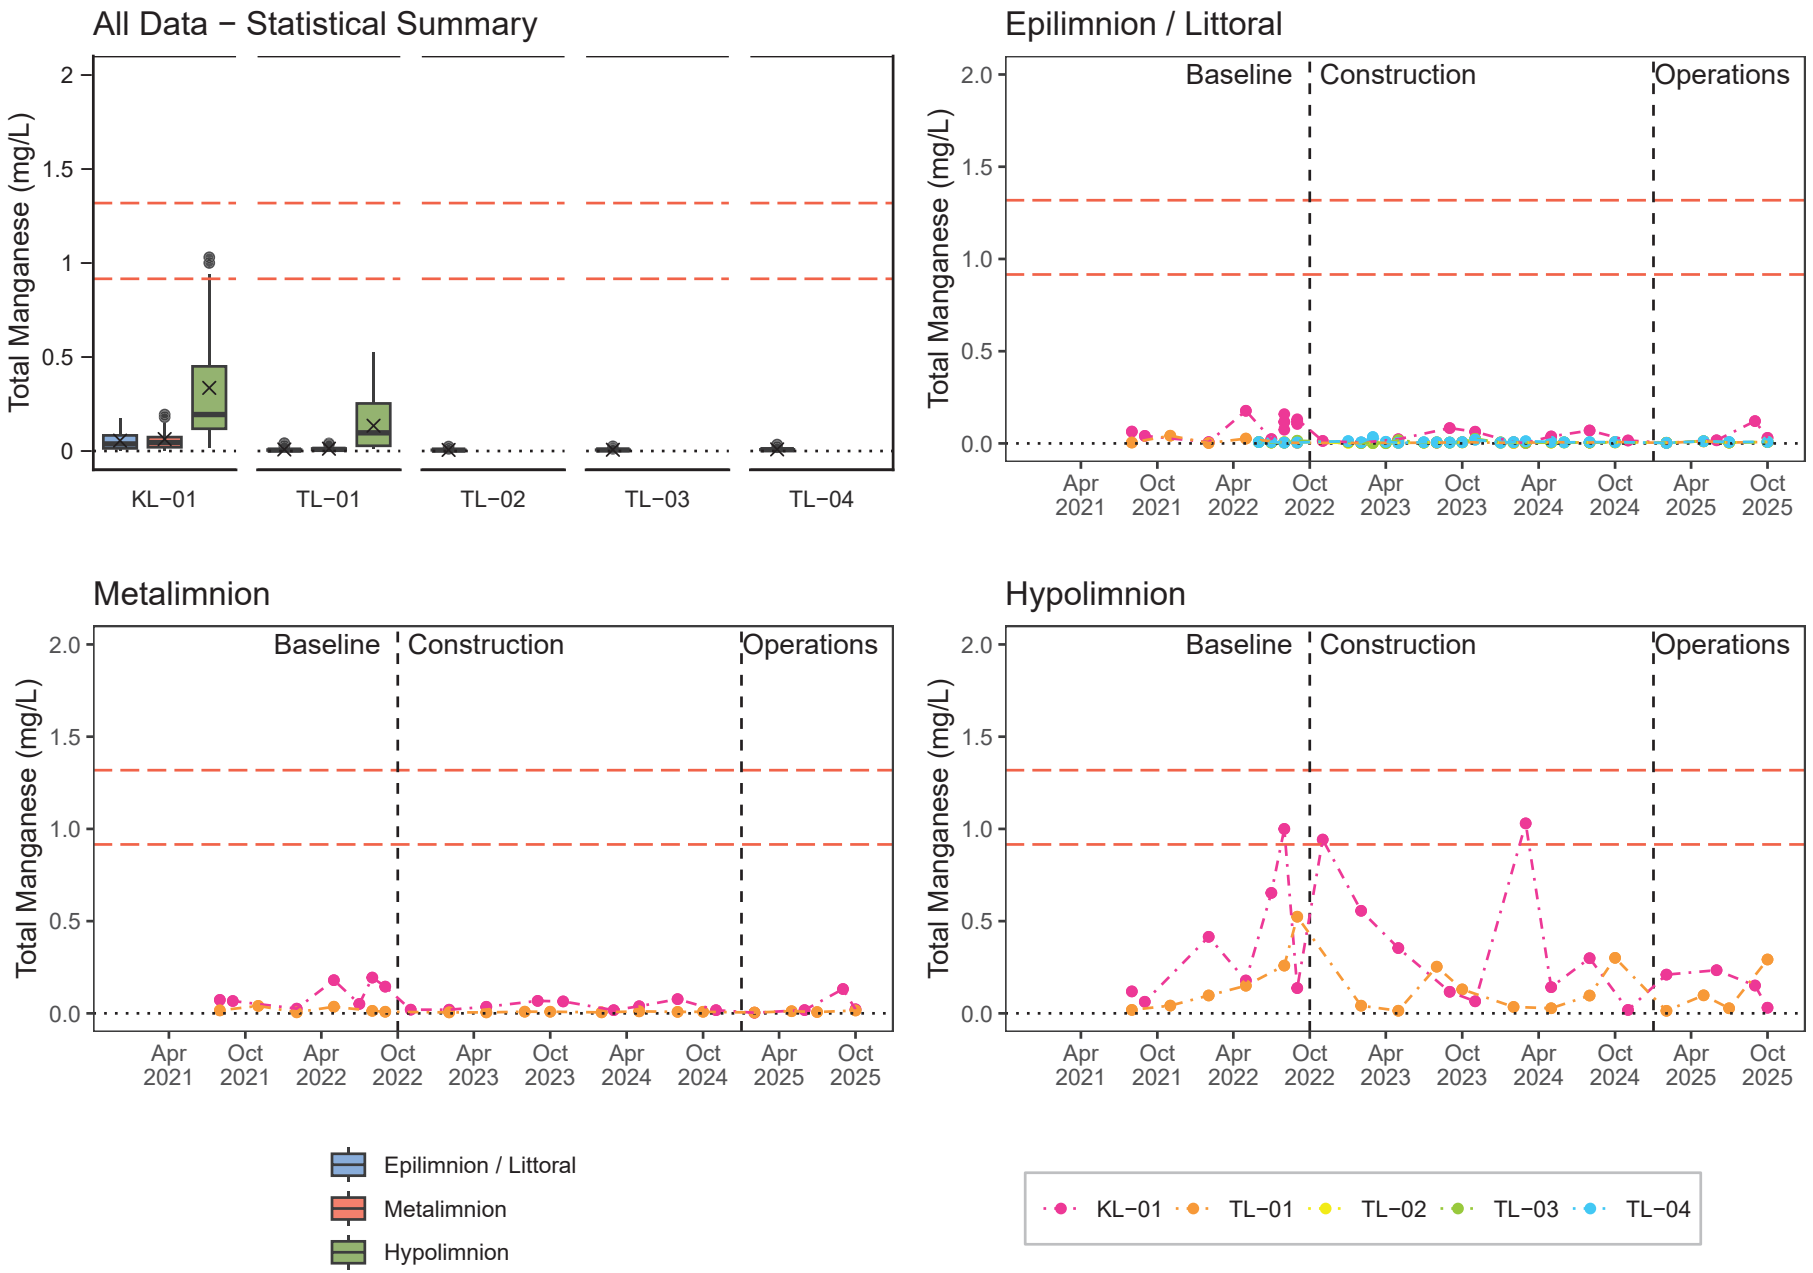
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−38: Total Lithium in AEMP Monitored Lakes, 2021 to 2025



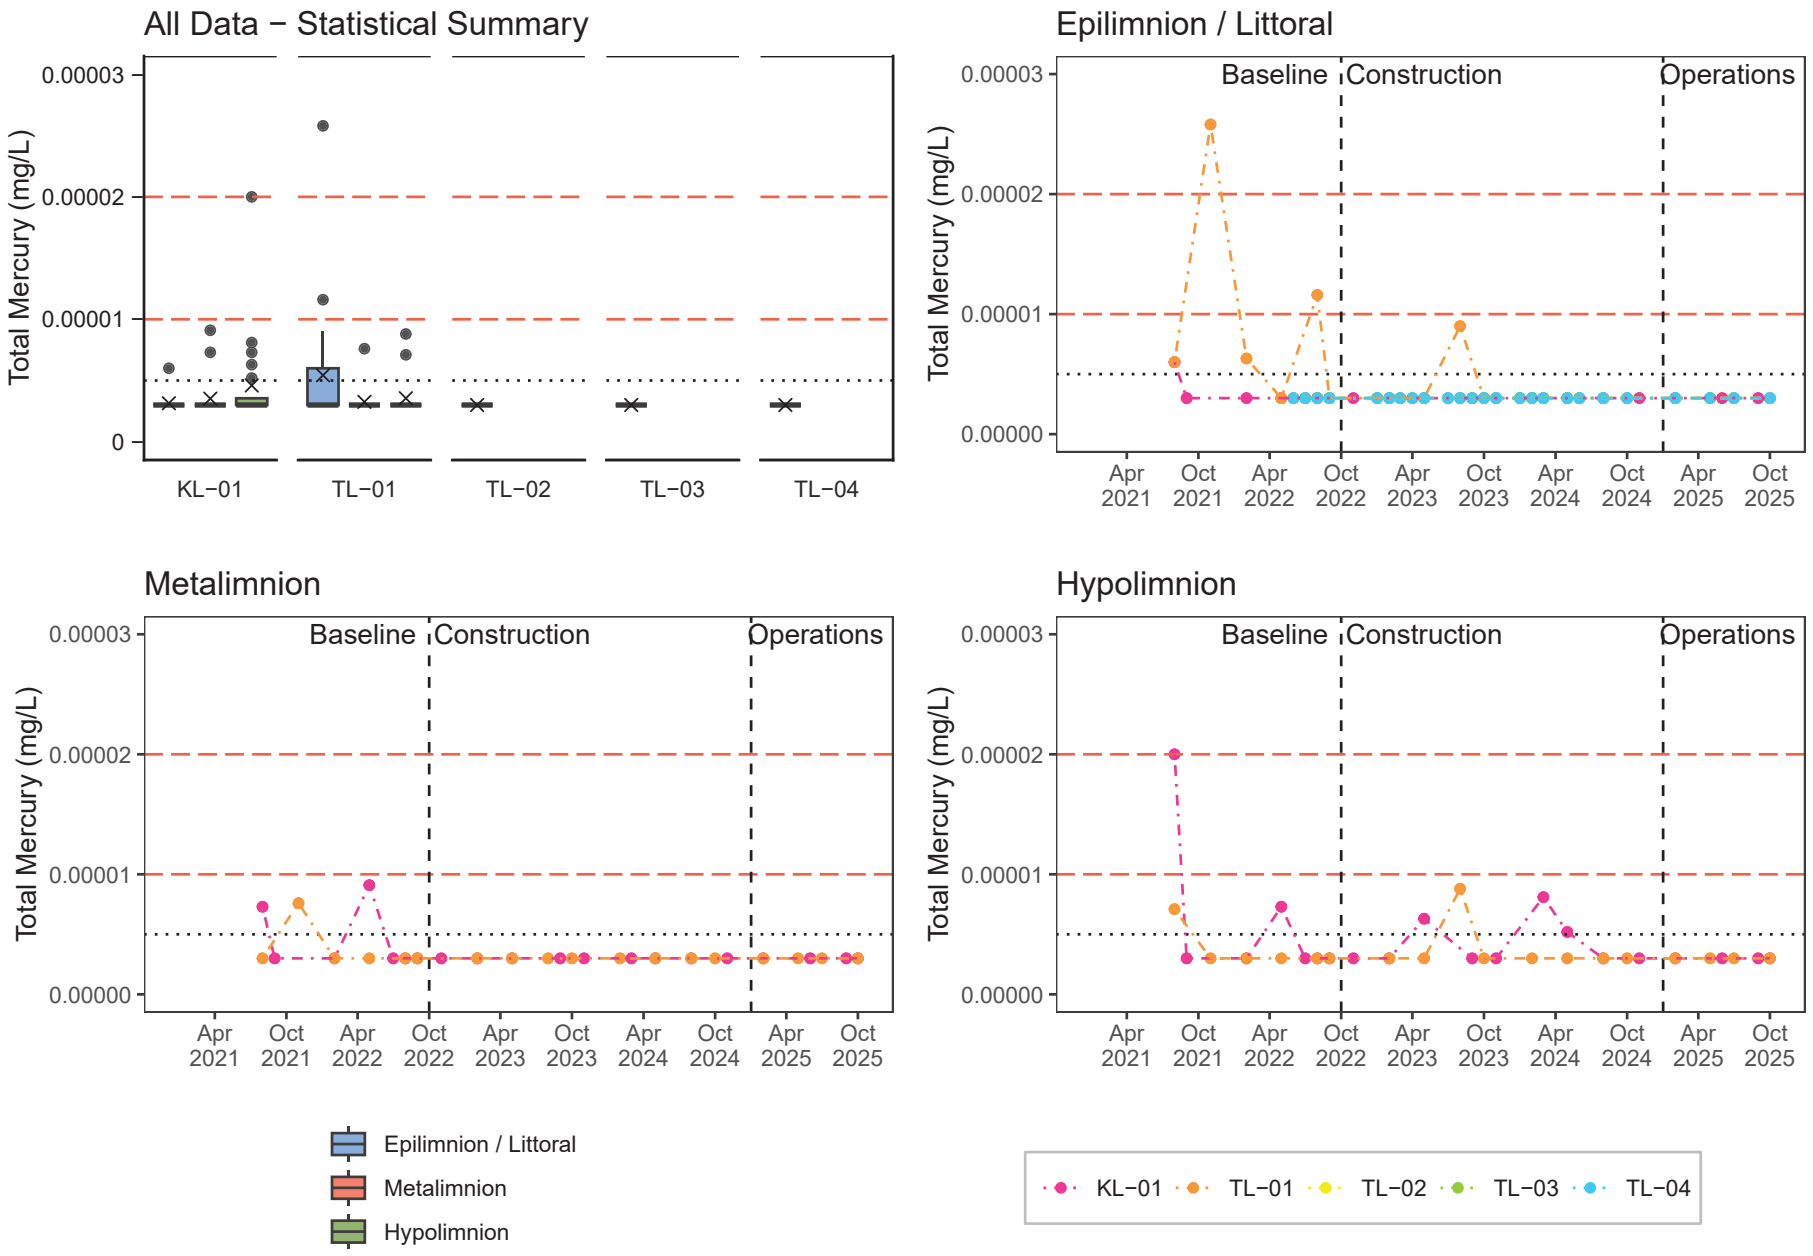
Notes: Dashed line indicates minimum detection limits.

Figure A9−39: Total Magnesium in AEMP Monitored Lakes, 2021 to 2025



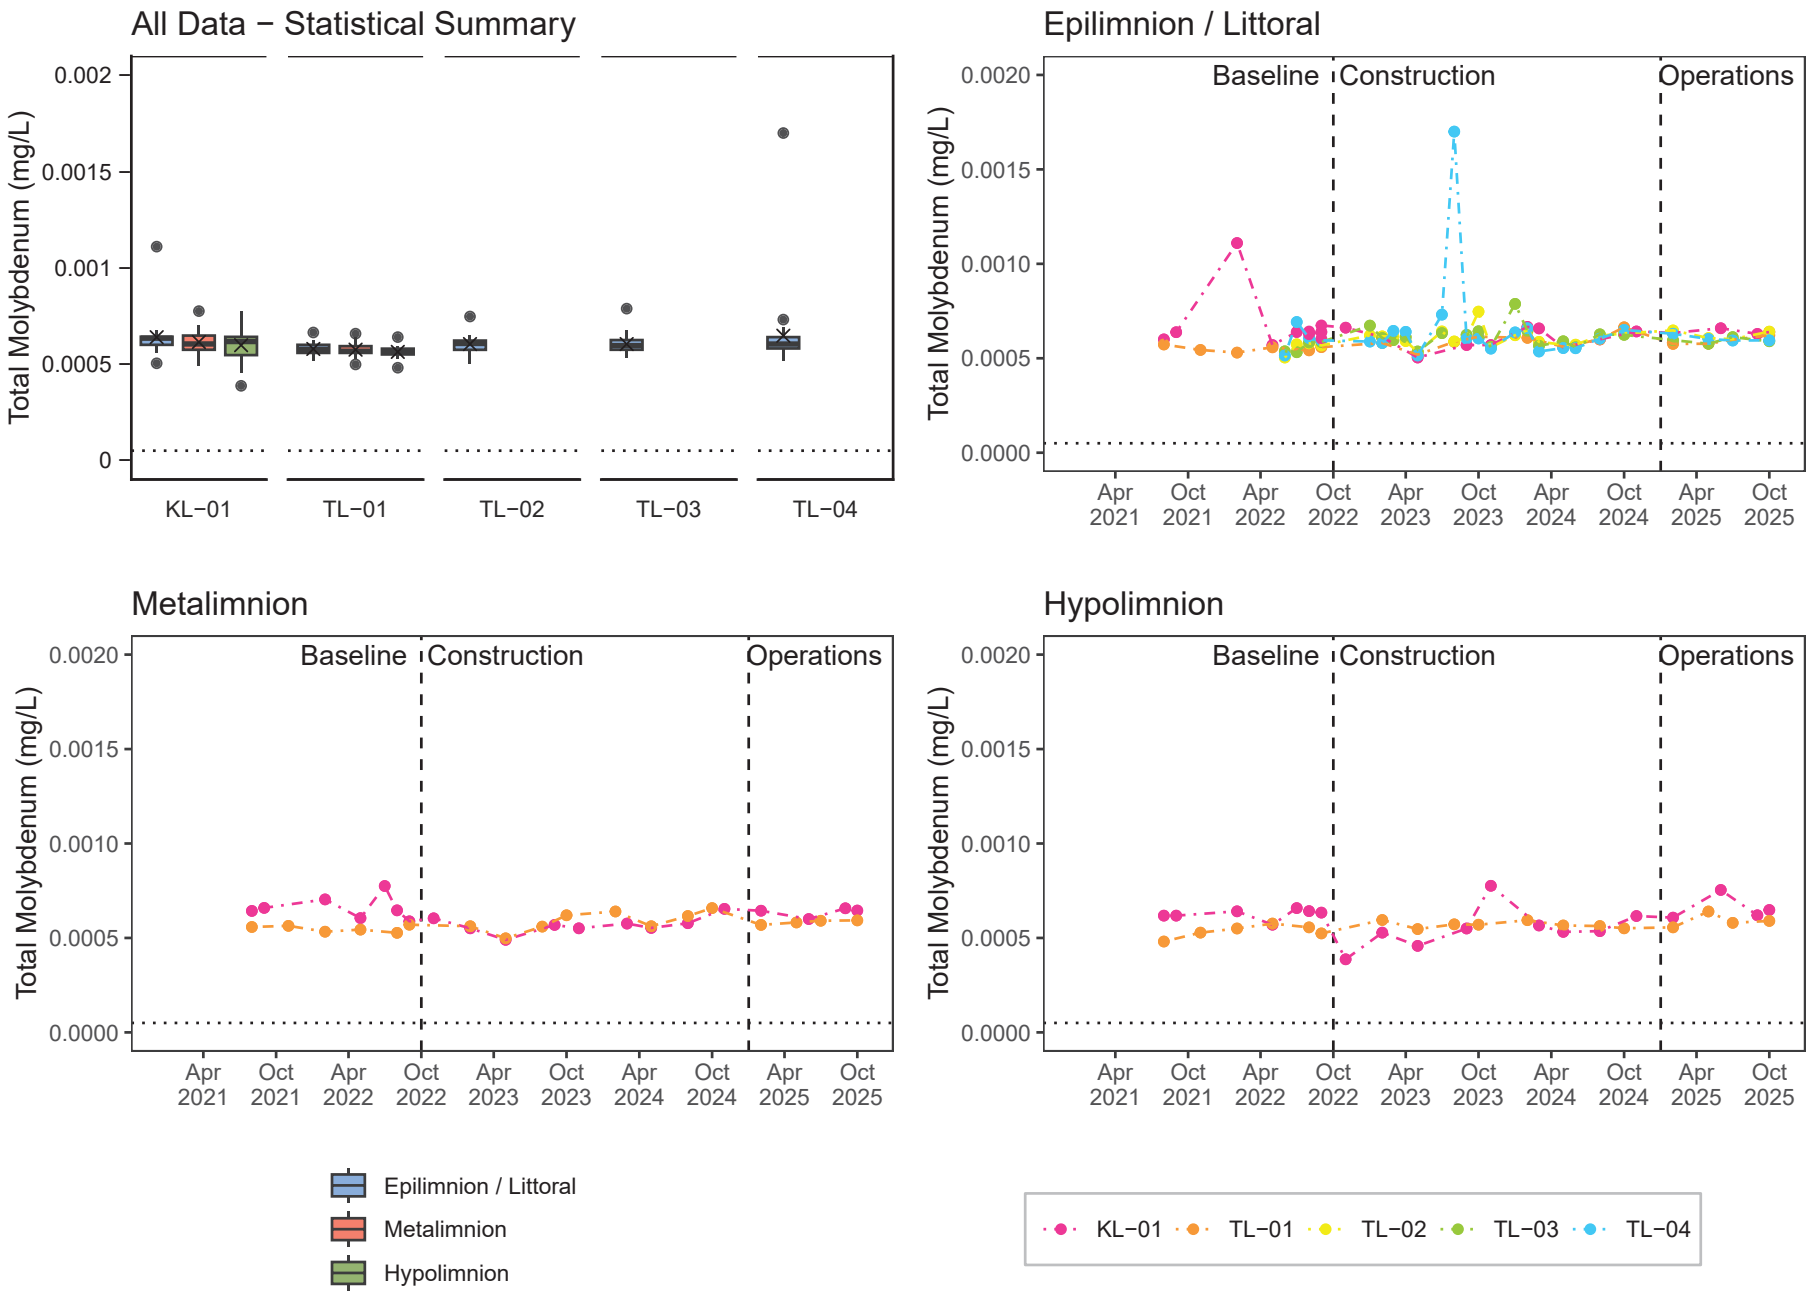
Notes: Dashed line indicates minimum detection limits.
Median BC WQG−AL long−term chronic guideline for total manganese for Project lakes is 0.91 mg/L.
Median BC WQG−AL short−term chronic guideline for total manganese for Project lakes is 1.30 mg/L.

Figure A9−40: Total Manganese in AEMP Monitored Lakes, 2021 to 2025



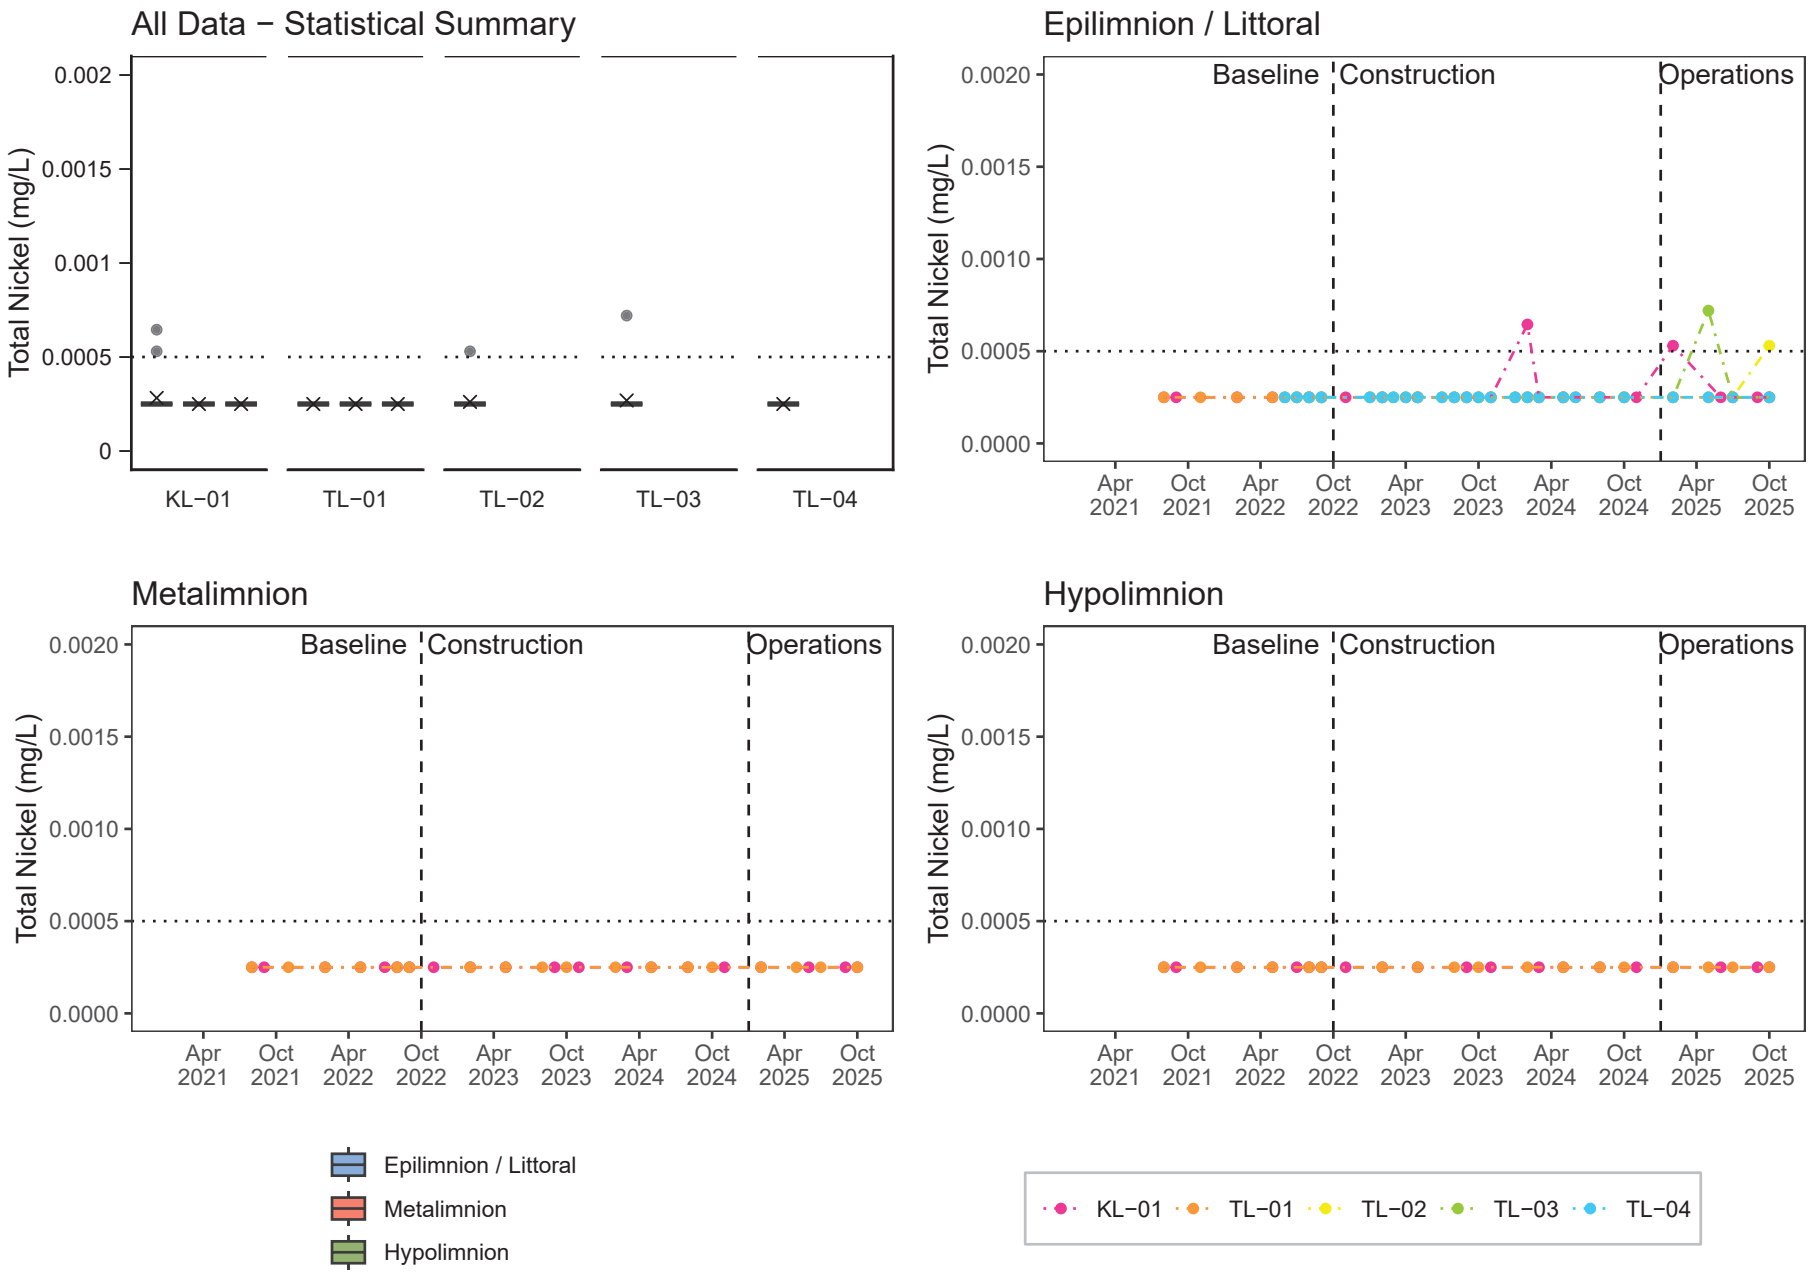
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.
BC WQG−AL long−term guideline for total mercury = 0.00002 mg/L, when MeHg = 0.5% THg.
BC WQG−AL long−term guideline for total mercury = 0.00001 mg/L, when MeHg = 1% THg.

Figure A9−41: Total Mercury in AEMP Monitored Lakes, 2021 to 2025



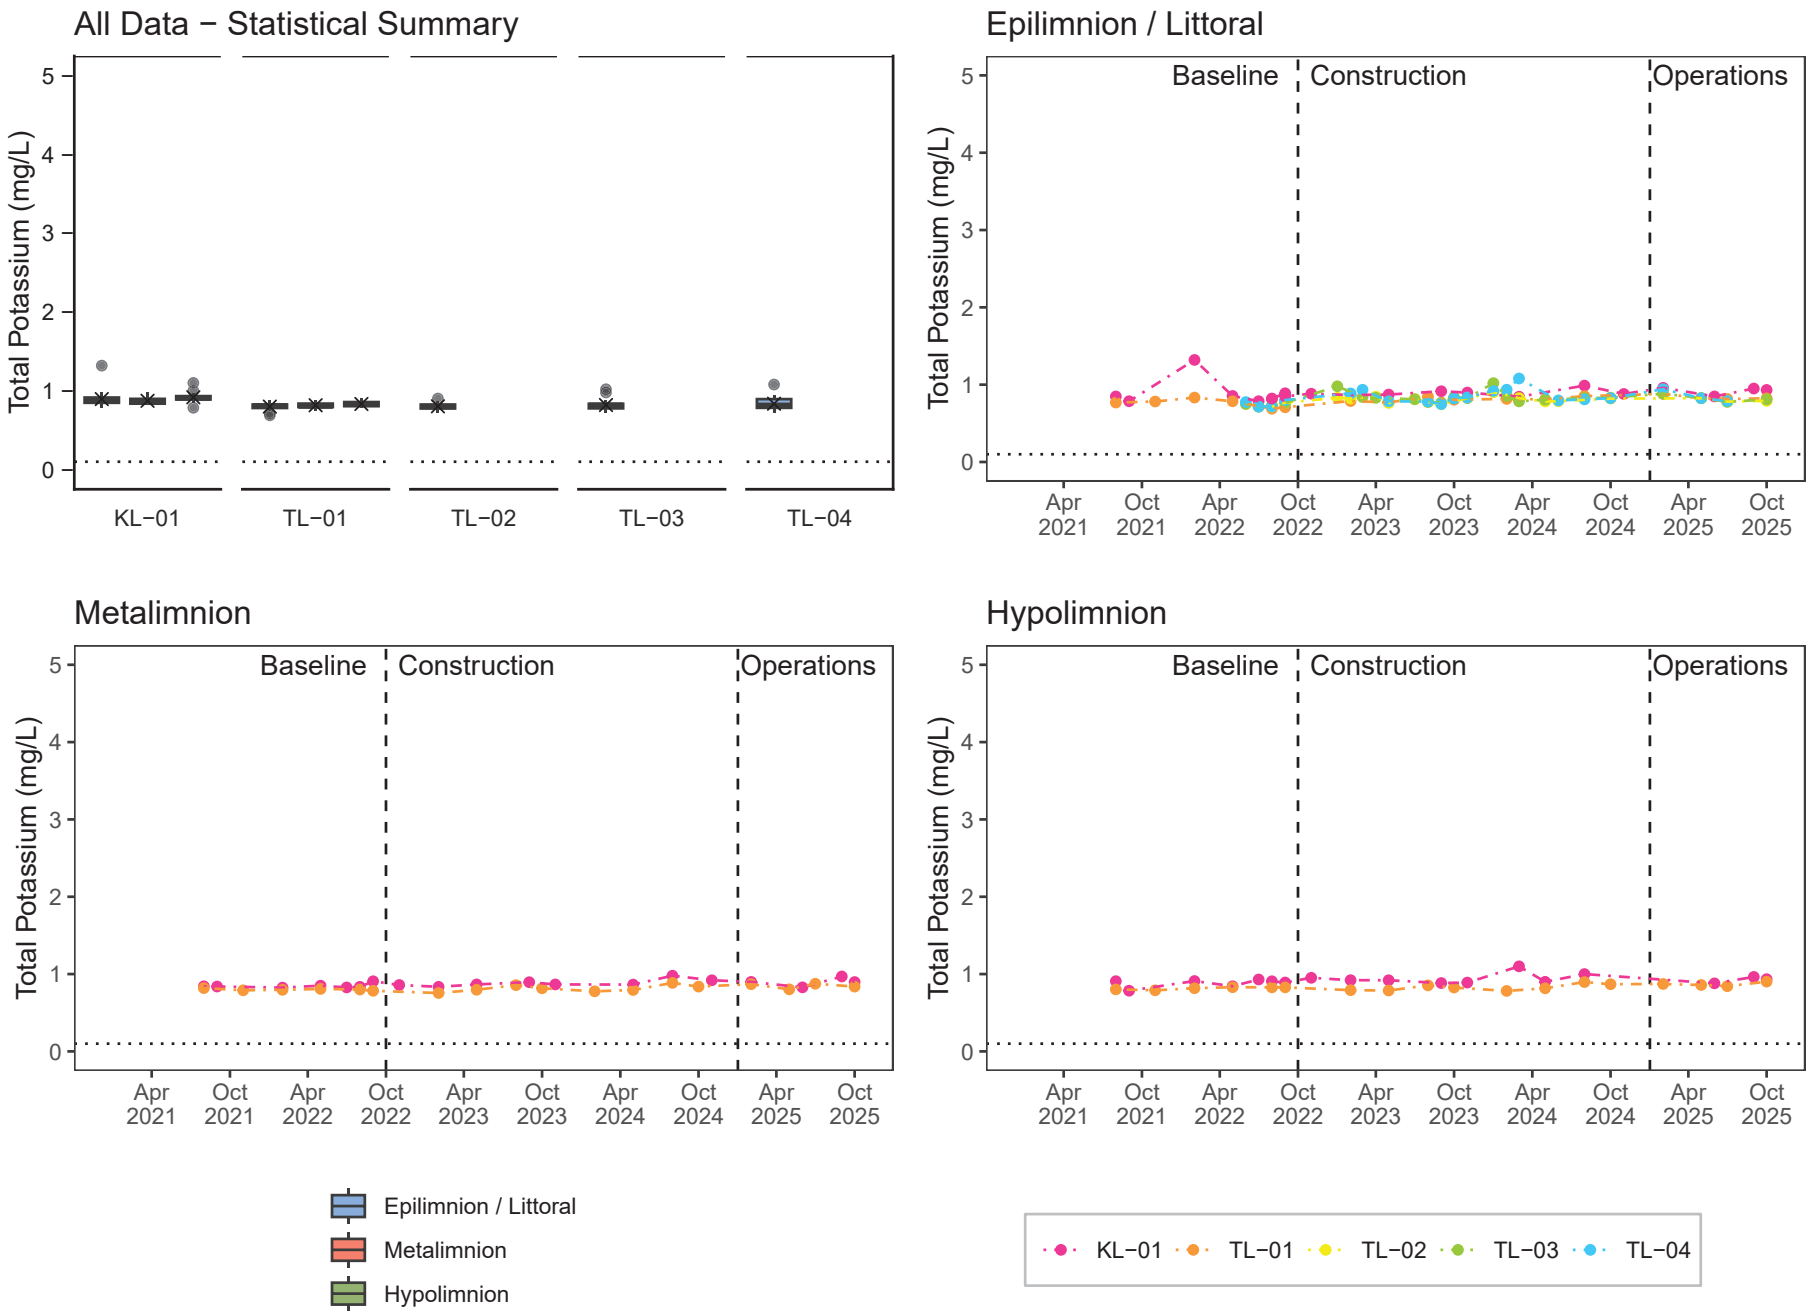
Notes: Dashed line indicates minimum detection limits.
BC WQG−AL 30−day long−term guideline for total molybedenum is 7.6 mg/L.

Figure A9−42: Total Molybdenum in AEMP Monitored Lakes, 2021 to 2025



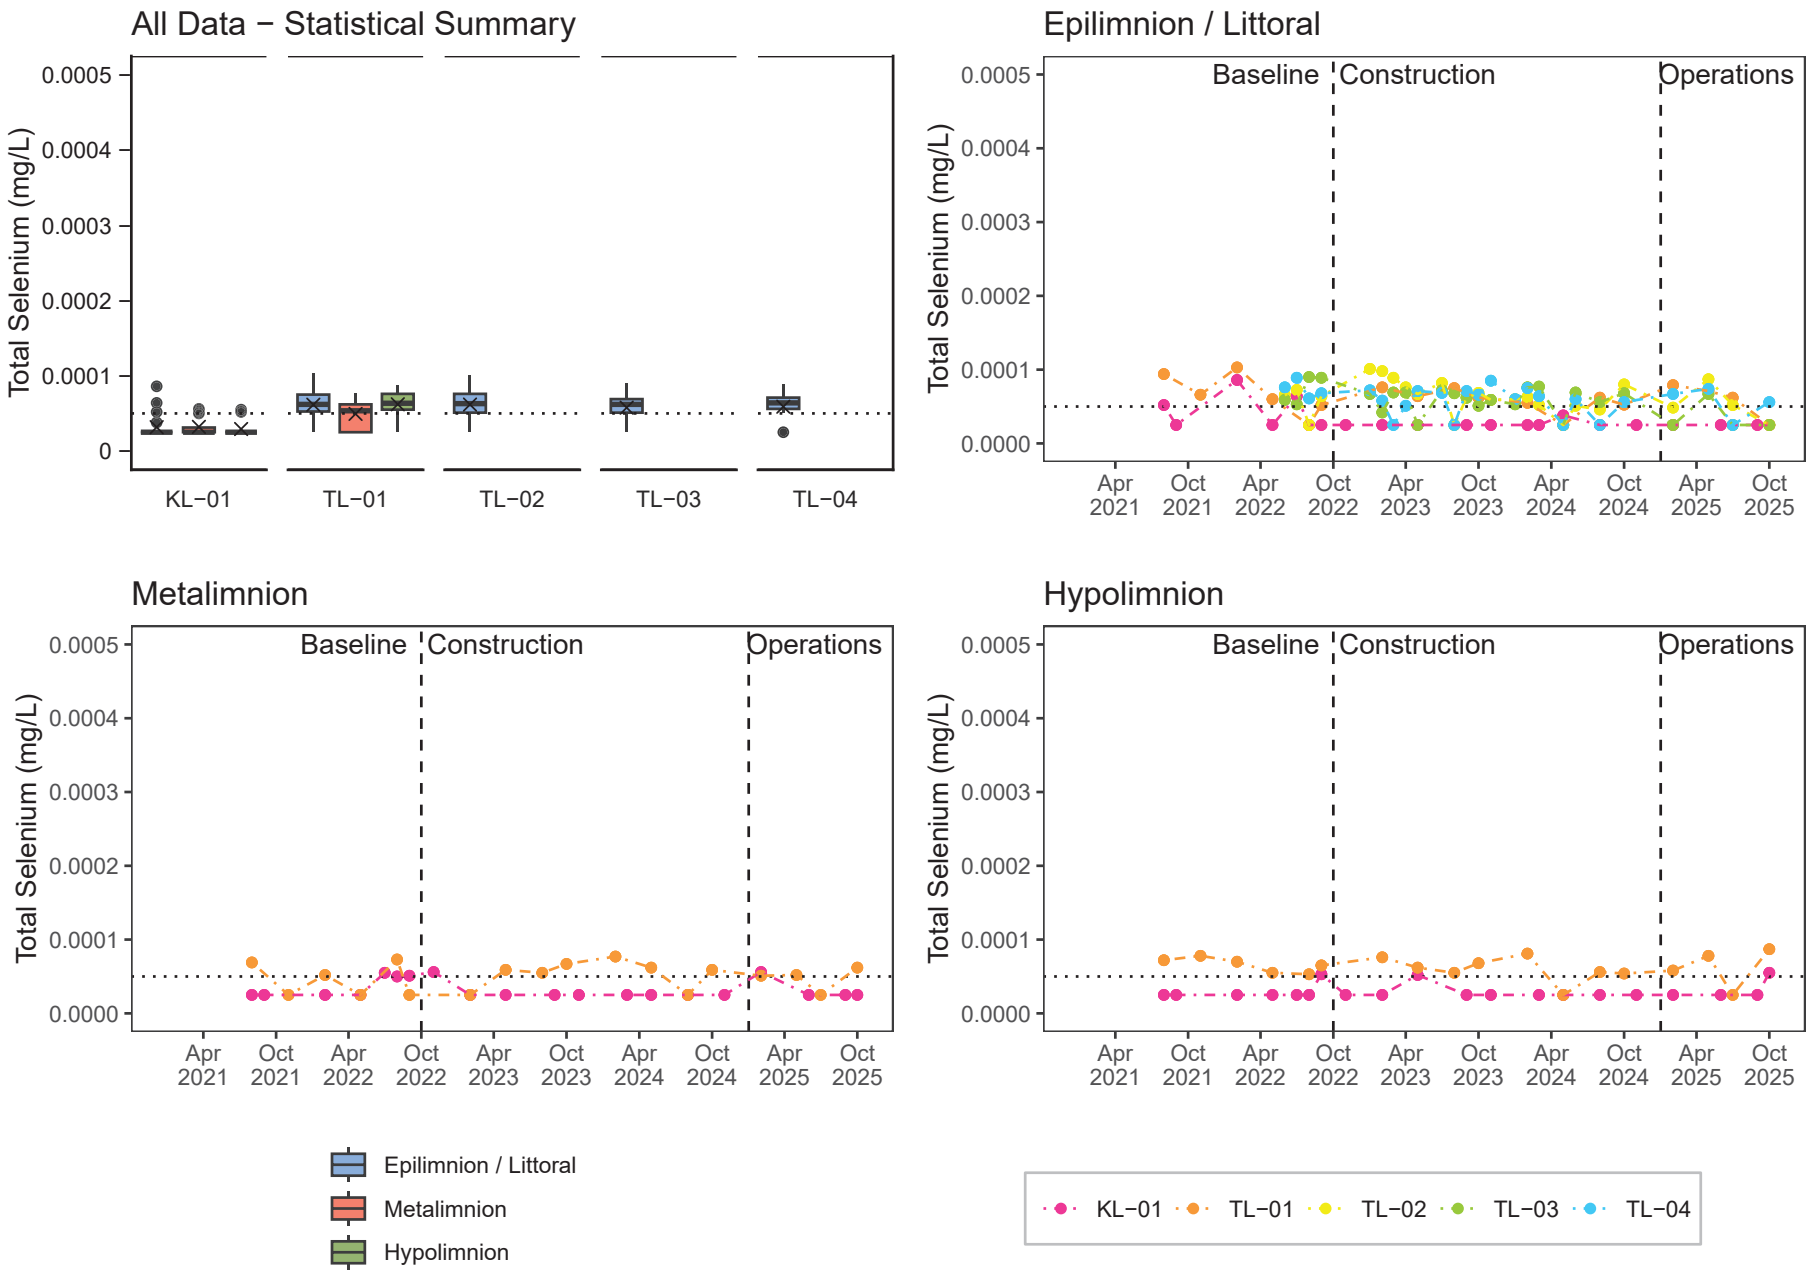
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.
CCME WQG−AL long−term 30−day guideline for total nickel is 0.0734 mg/L.

Figure A9−43: Total Nickel in AEMP Monitored Lakes, 2021 to 2025



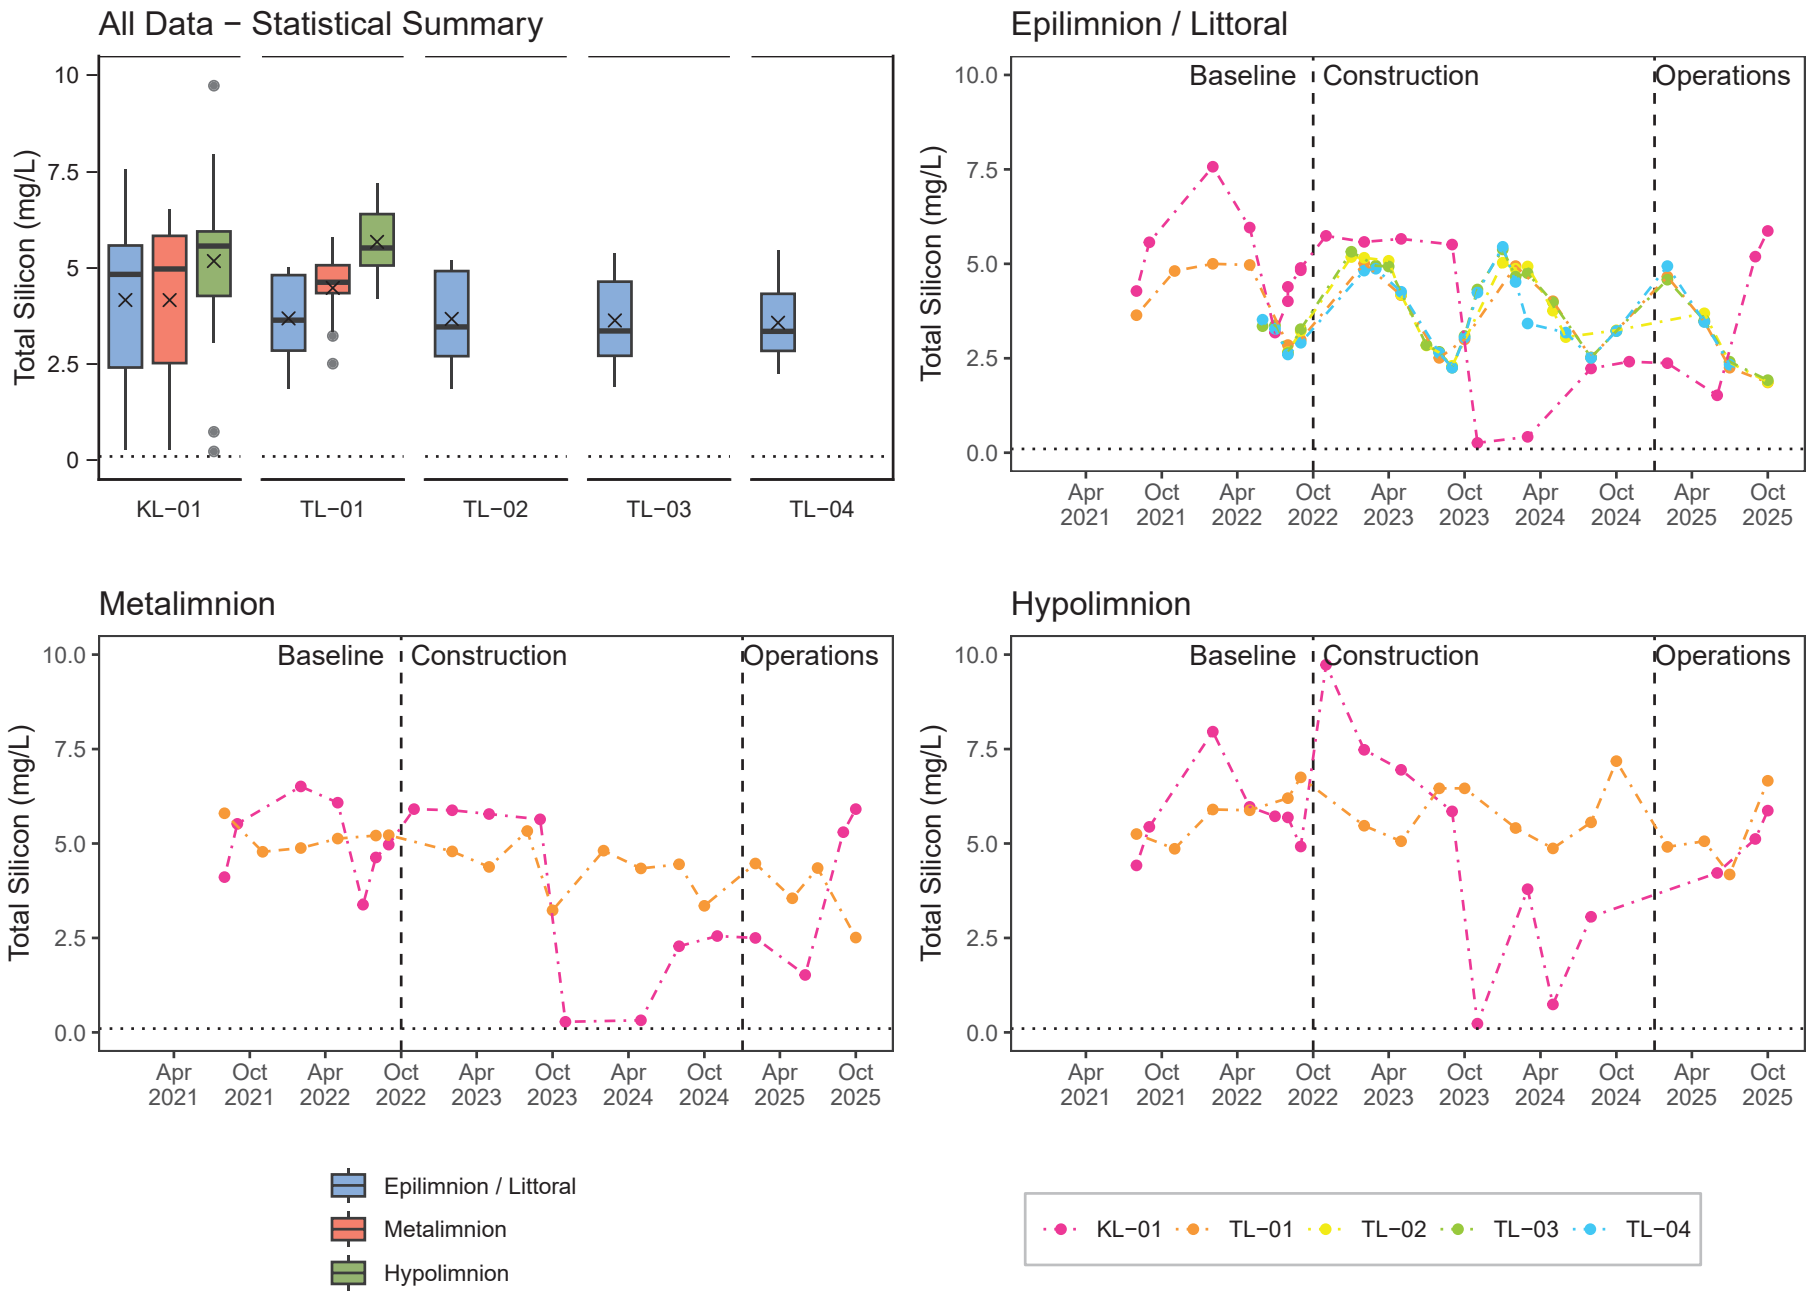
Notes: Dashed line indicates minimum detection limits.

Figure A9−44: Total Potassium in AEMP Monitored Lakes, 2021 to 2025



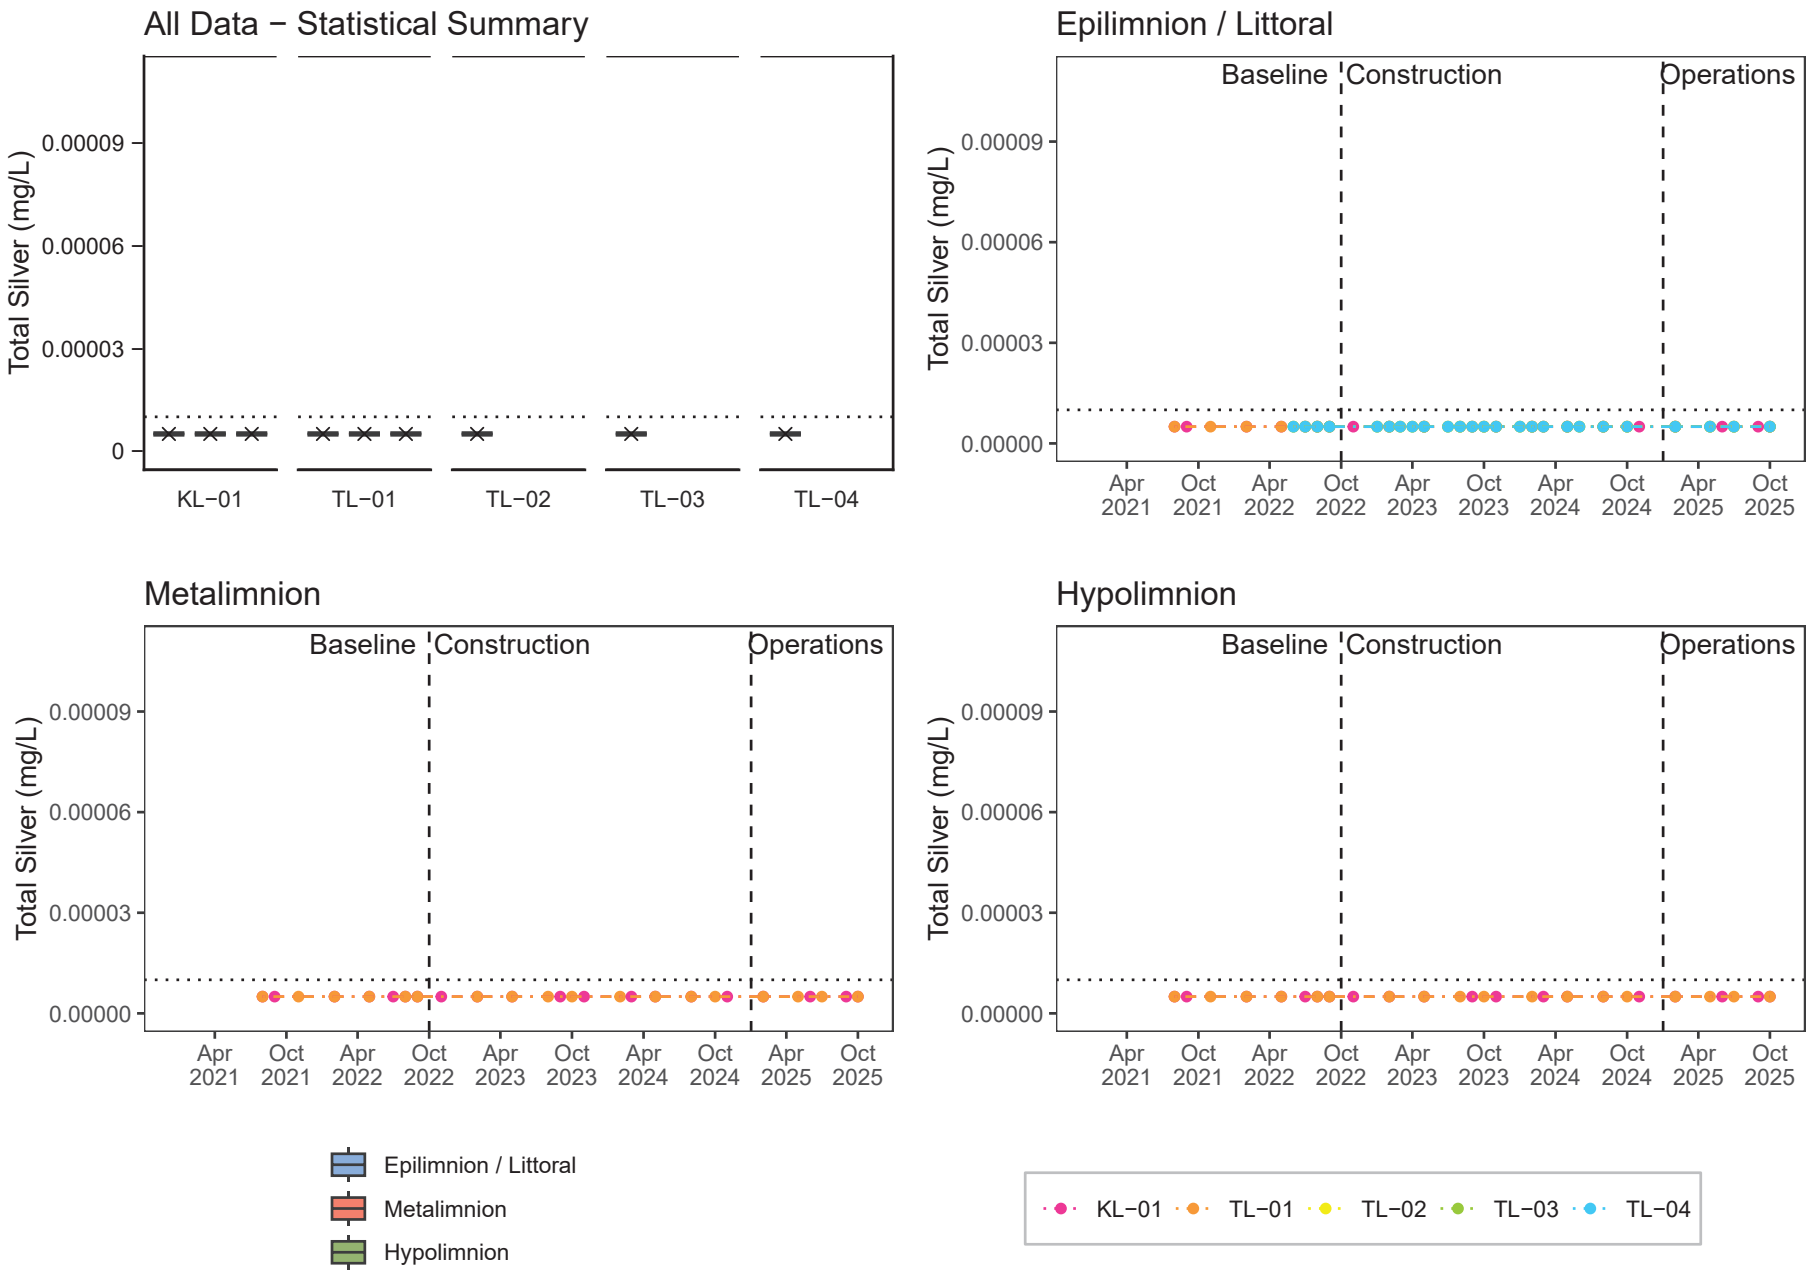
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.
BC WQG−AL long−term guideline for total selenium is 0.002 mg/L.

Figure A9−45: Total Selenium in AEMP Monitored Lakes, 2021 to 2025



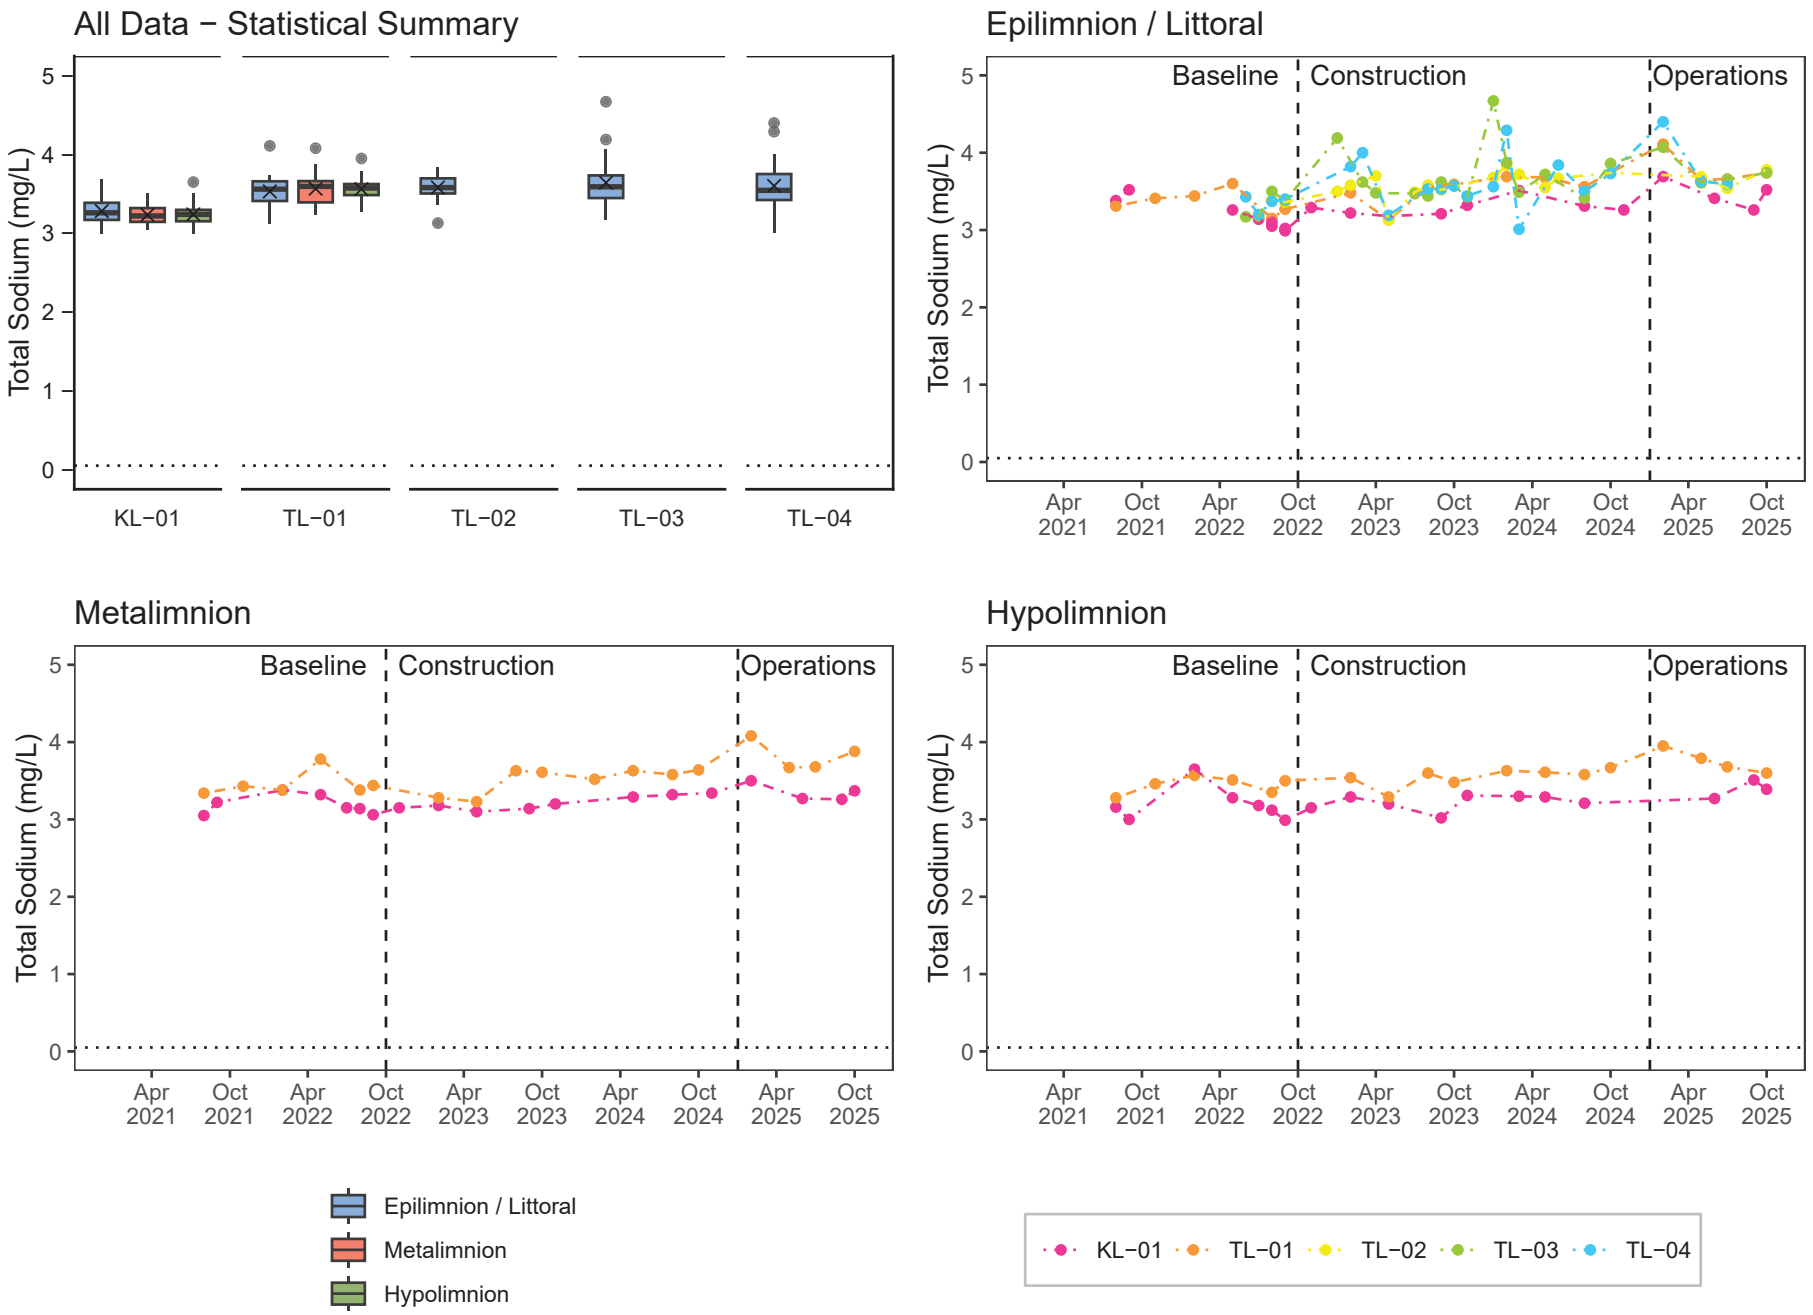
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−46: Total Silicon in AEMP Monitored Lakes, 2021 to 2025



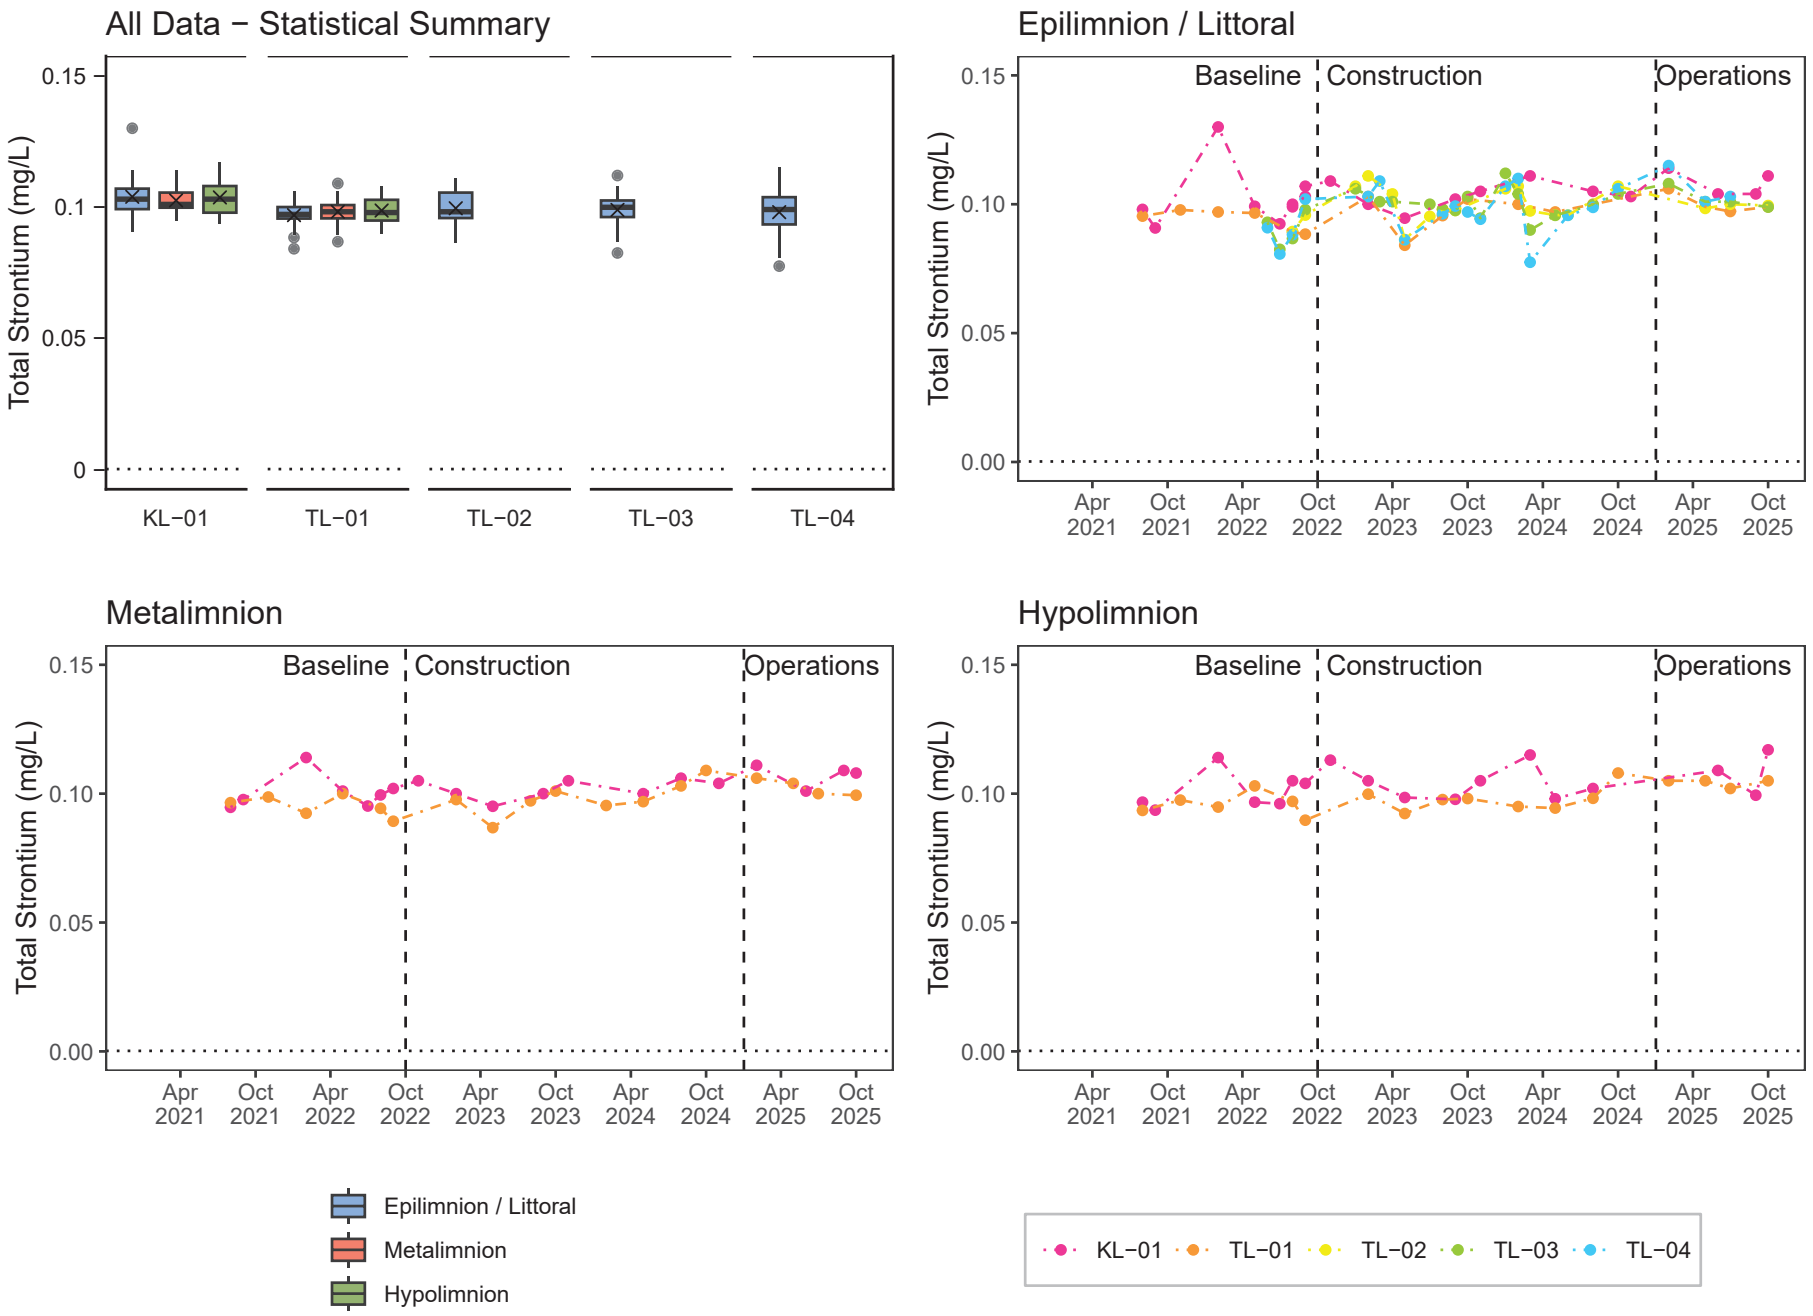
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.
Median BC WQG−AL long−term chronic guideline for total silver for Project lakes is 0.00012 mg/L.

Figure A9−47: Total Silver in AEMP Monitored Lakes, 2021 to 2025



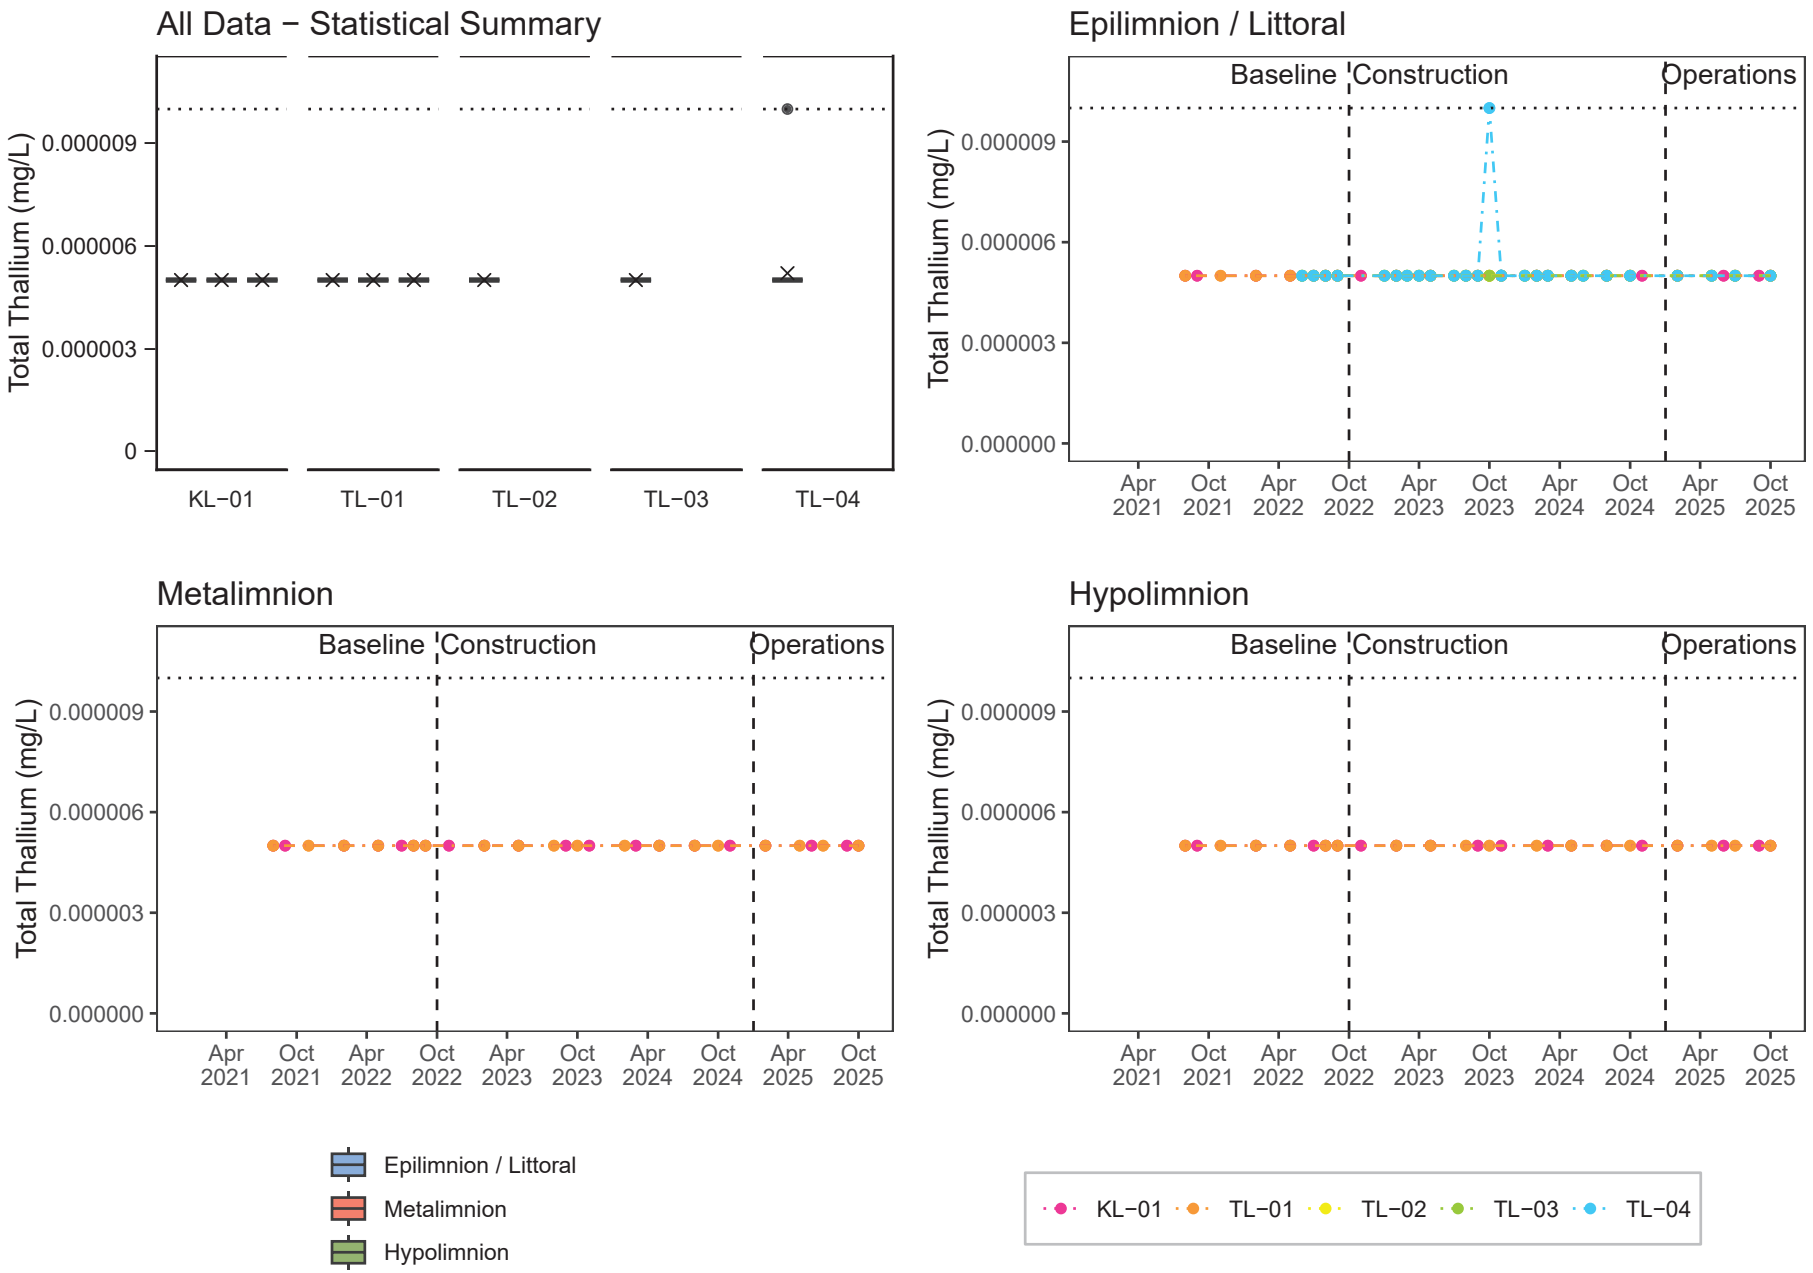
Notes: Dashed line indicates minimum detection limits.

Figure A9−48: Total Sodium in AEMP Monitored Lakes, 2021 to 2025



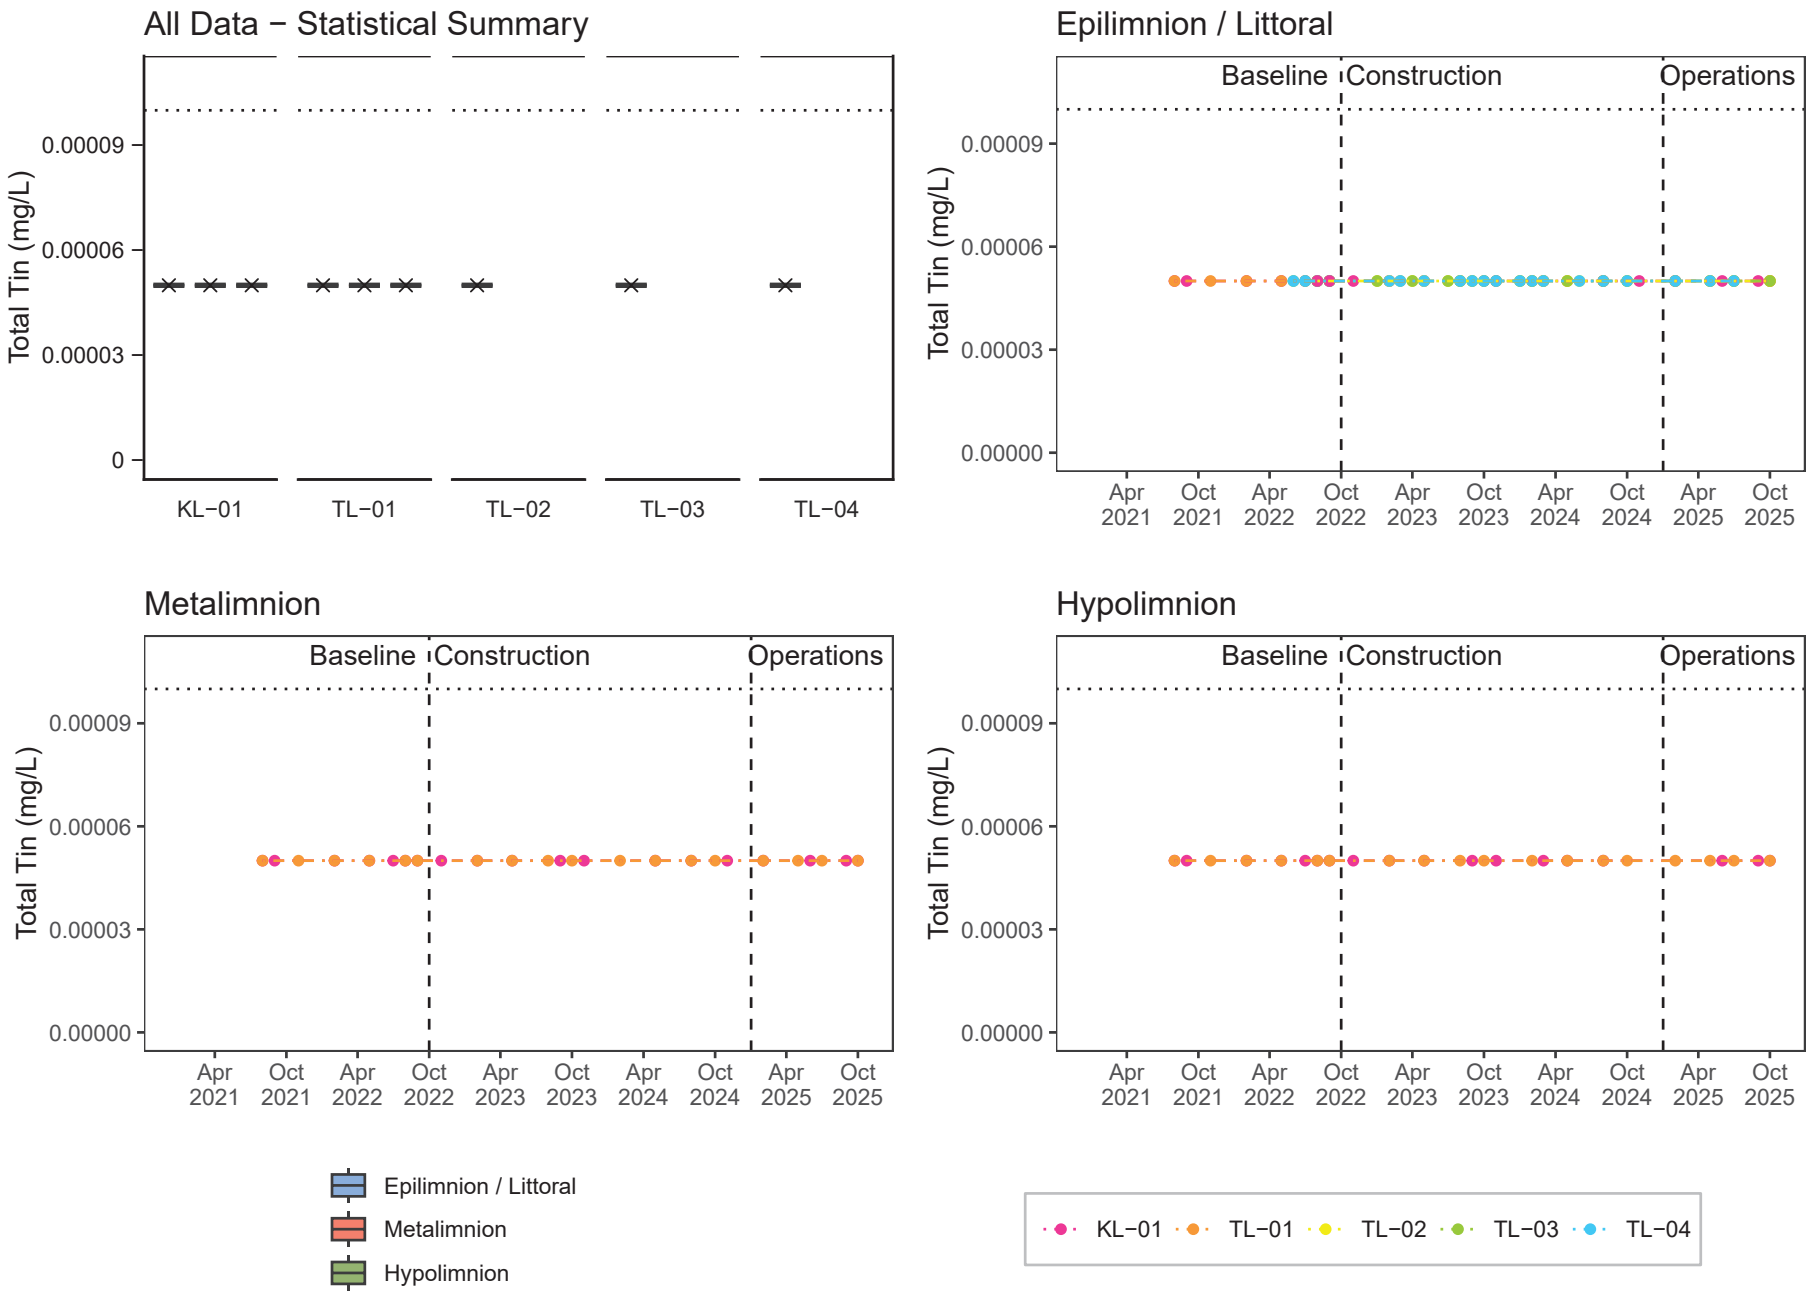
Notes: Dashed line indicates minimum detection limits.

Figure A9−49: Total Strontium in AEMP Monitored Lakes, 2021 to 2025



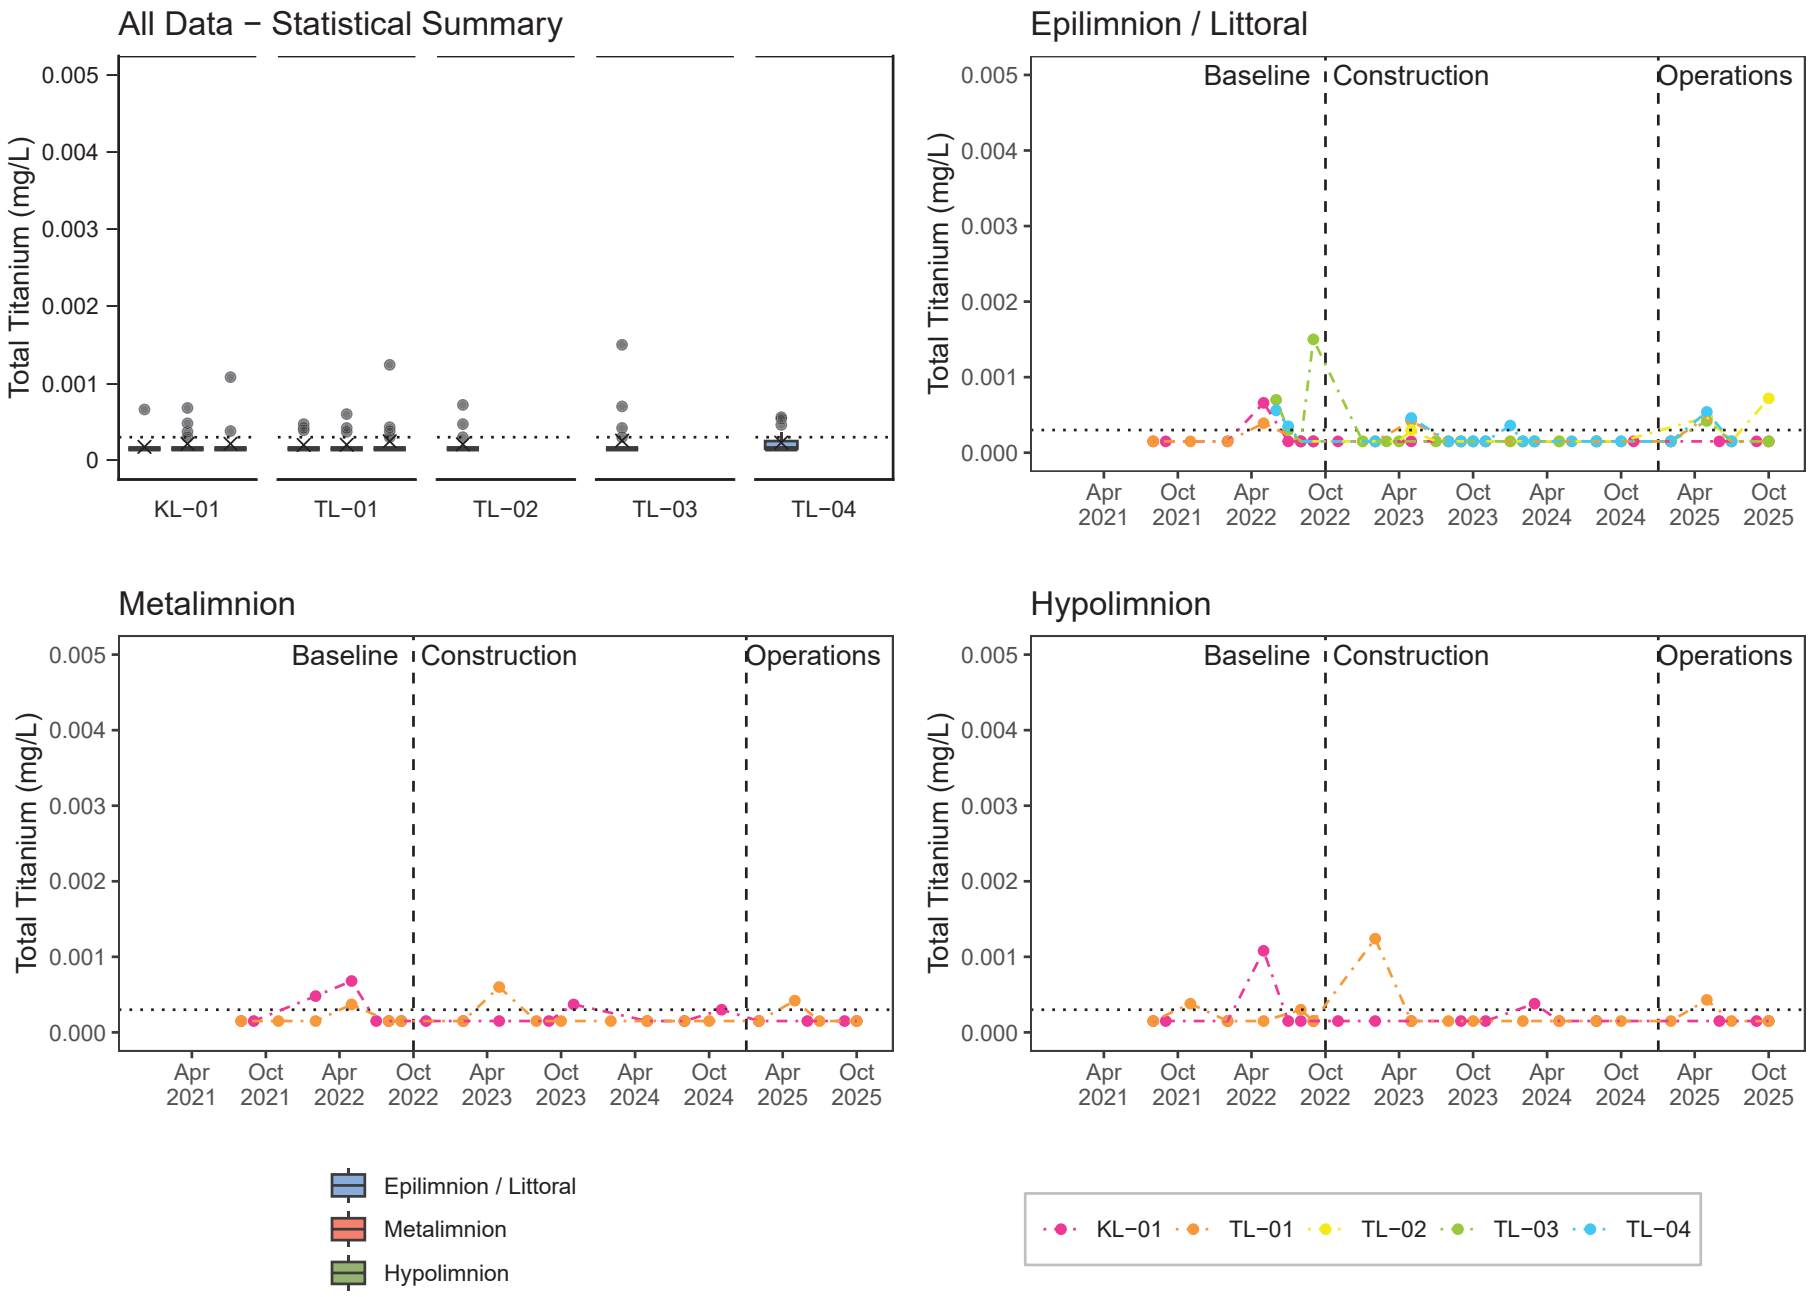
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.
BC WQG−AL working long−term guideline for total thallium is 0.00003 mg/L.

Figure A9−50: Total Thallium in AEMP Monitored Lakes, 2021 to 2025



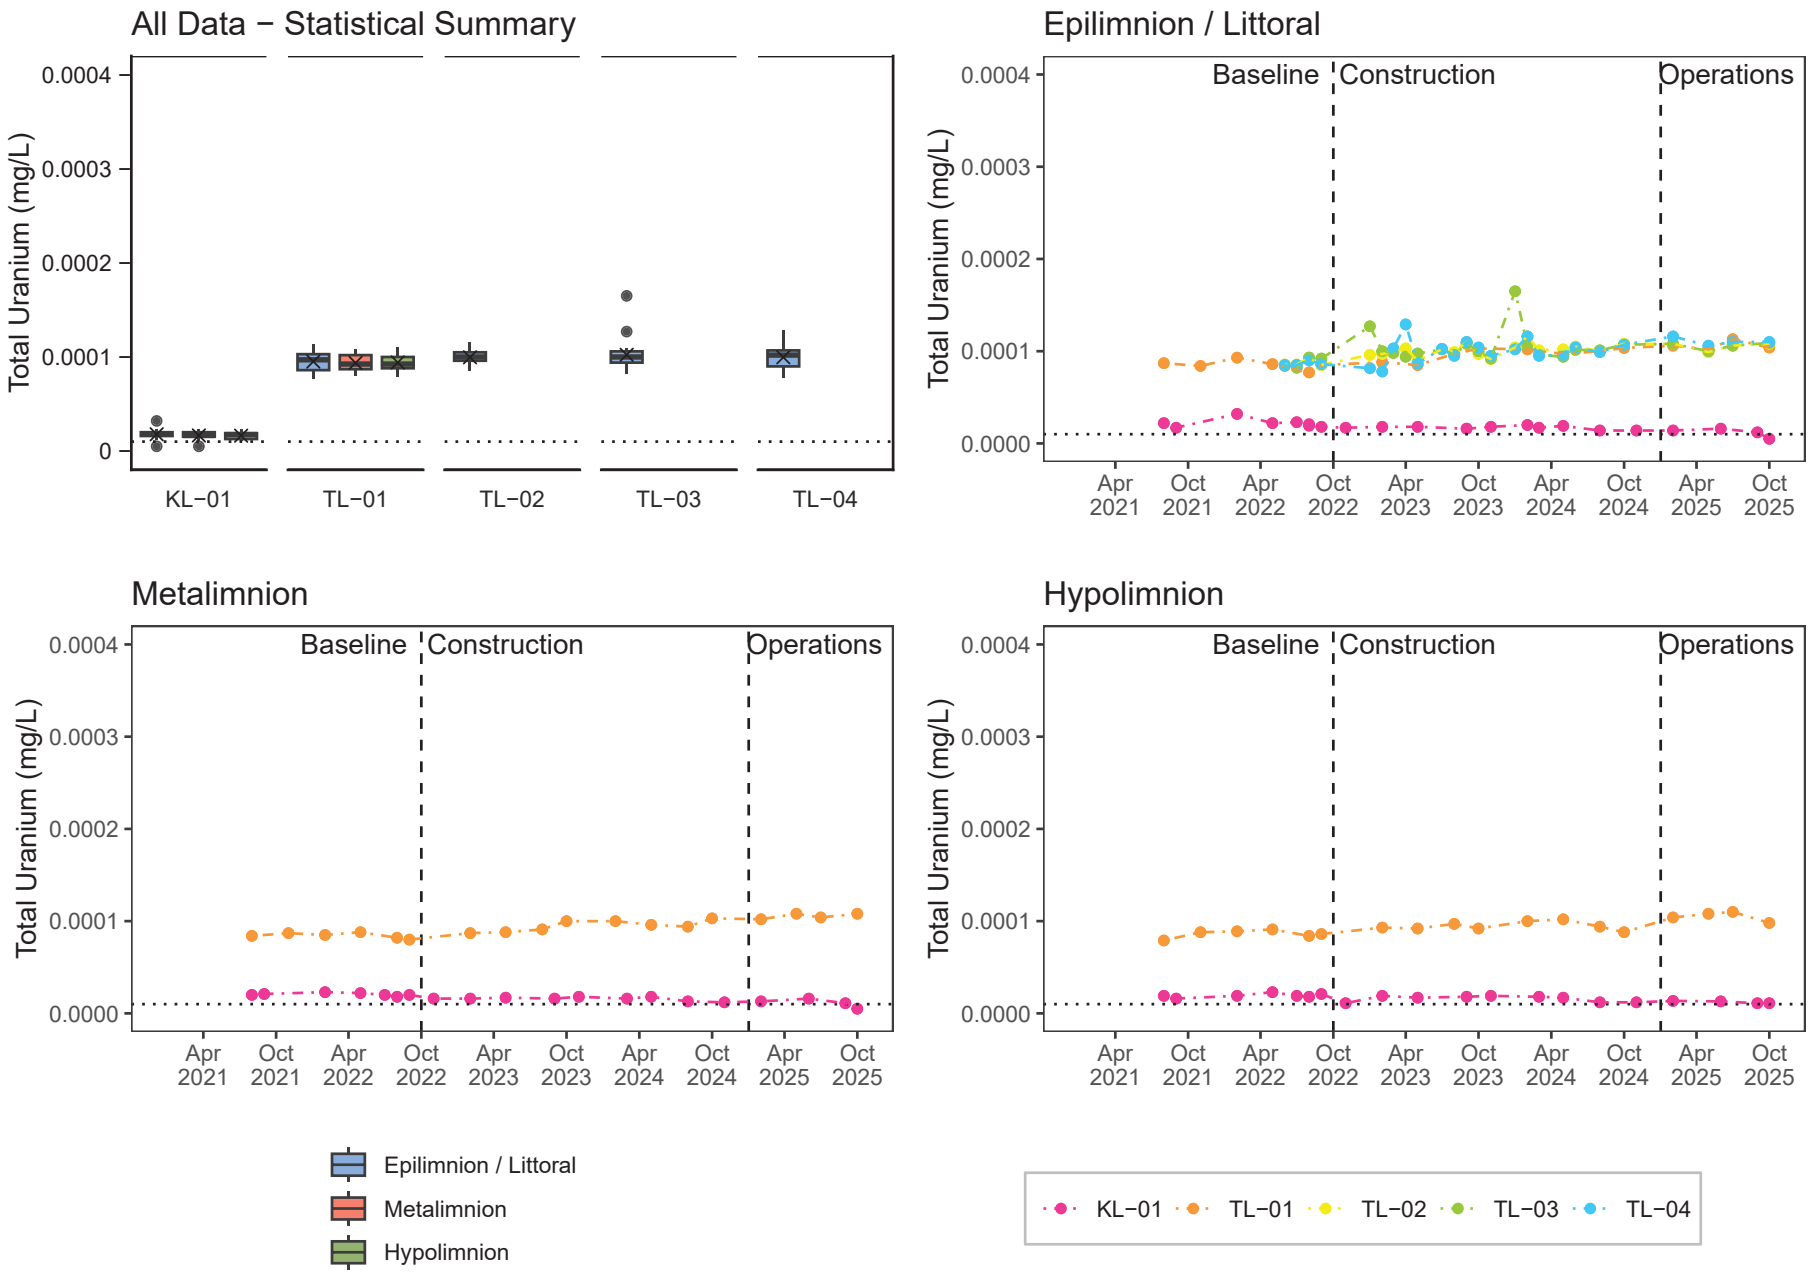
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−51: Total Tin in AEMP Monitored Lakes, 2021 to 2025



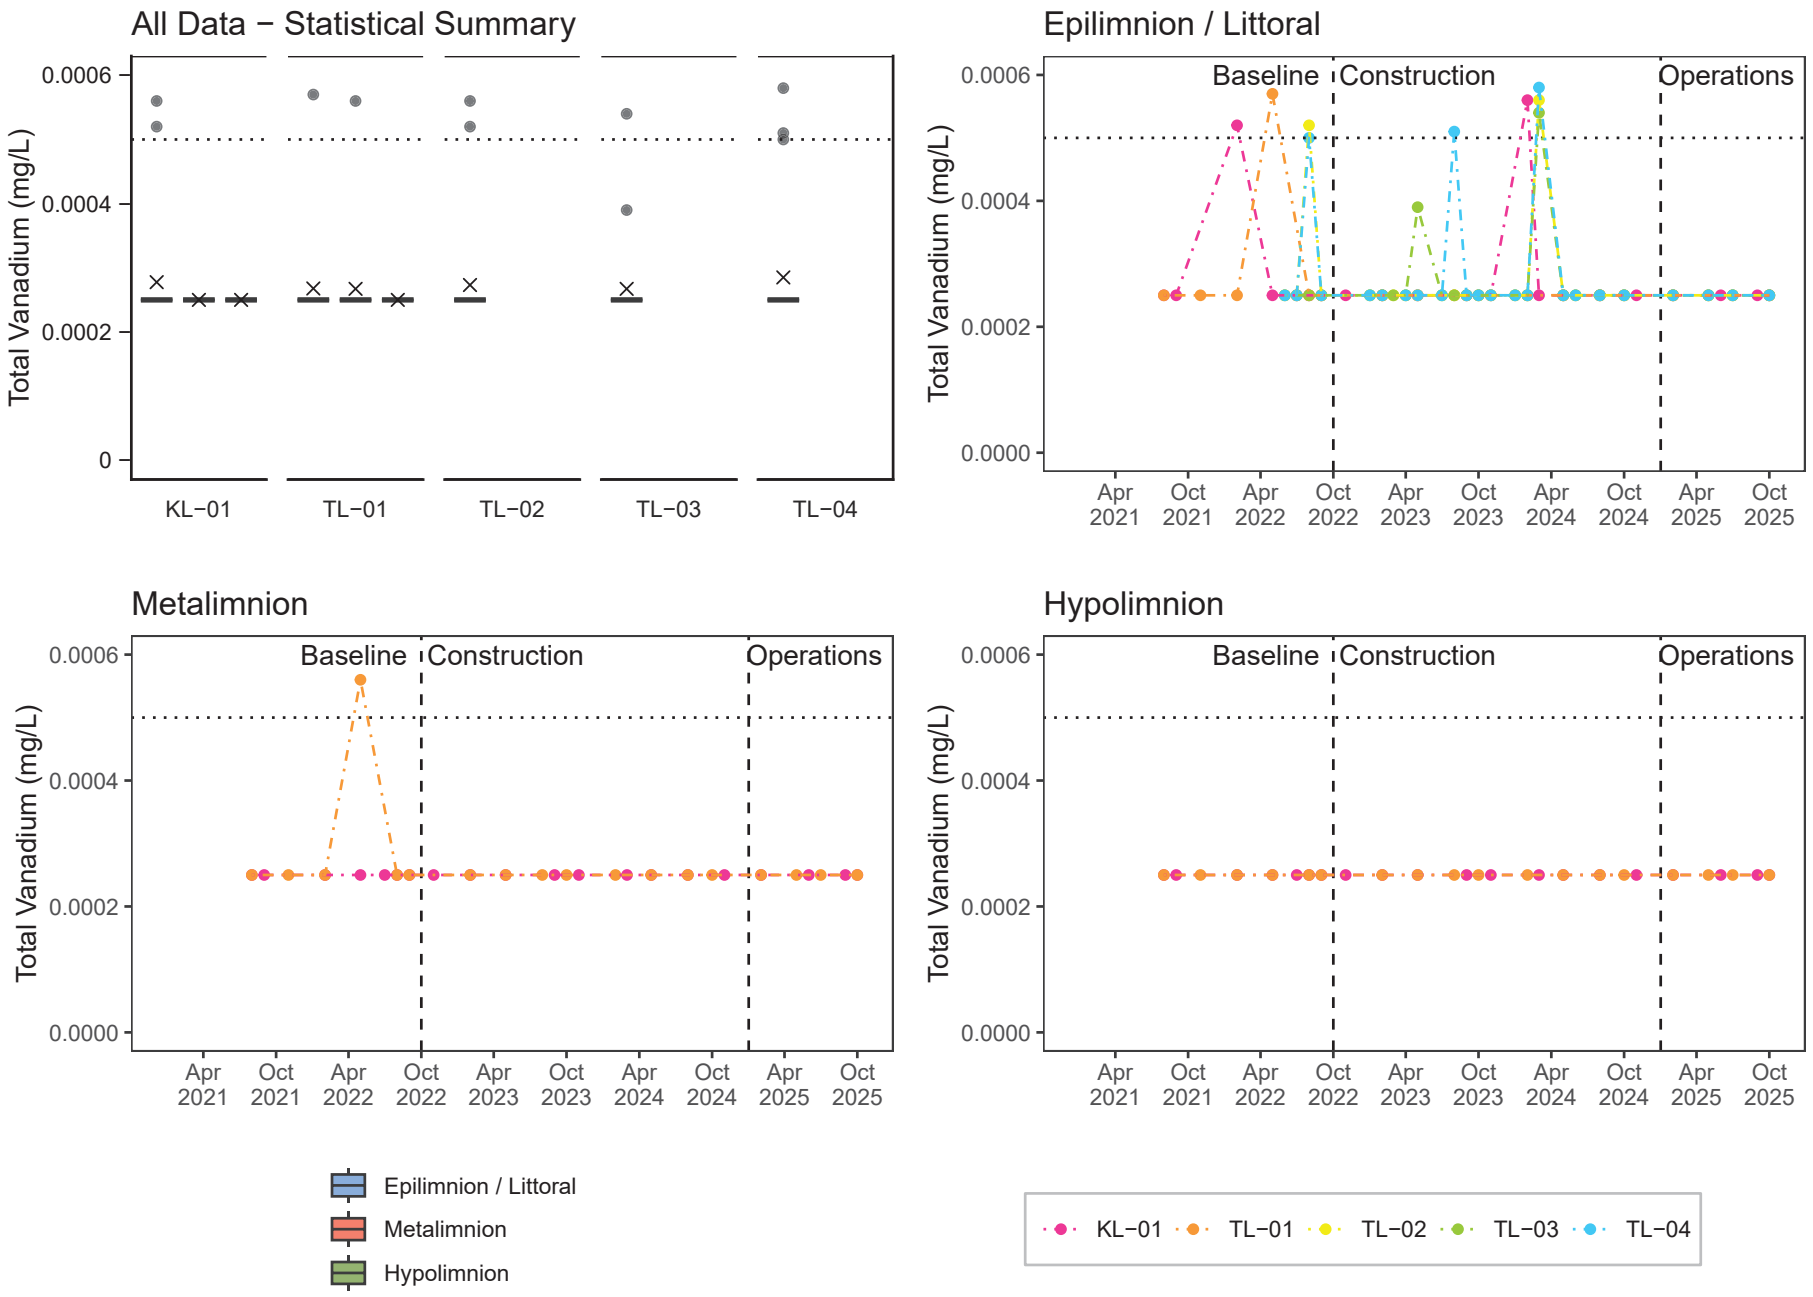
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−52: Total Titanium in AEMP Monitored Lakes, 2021 to 2025



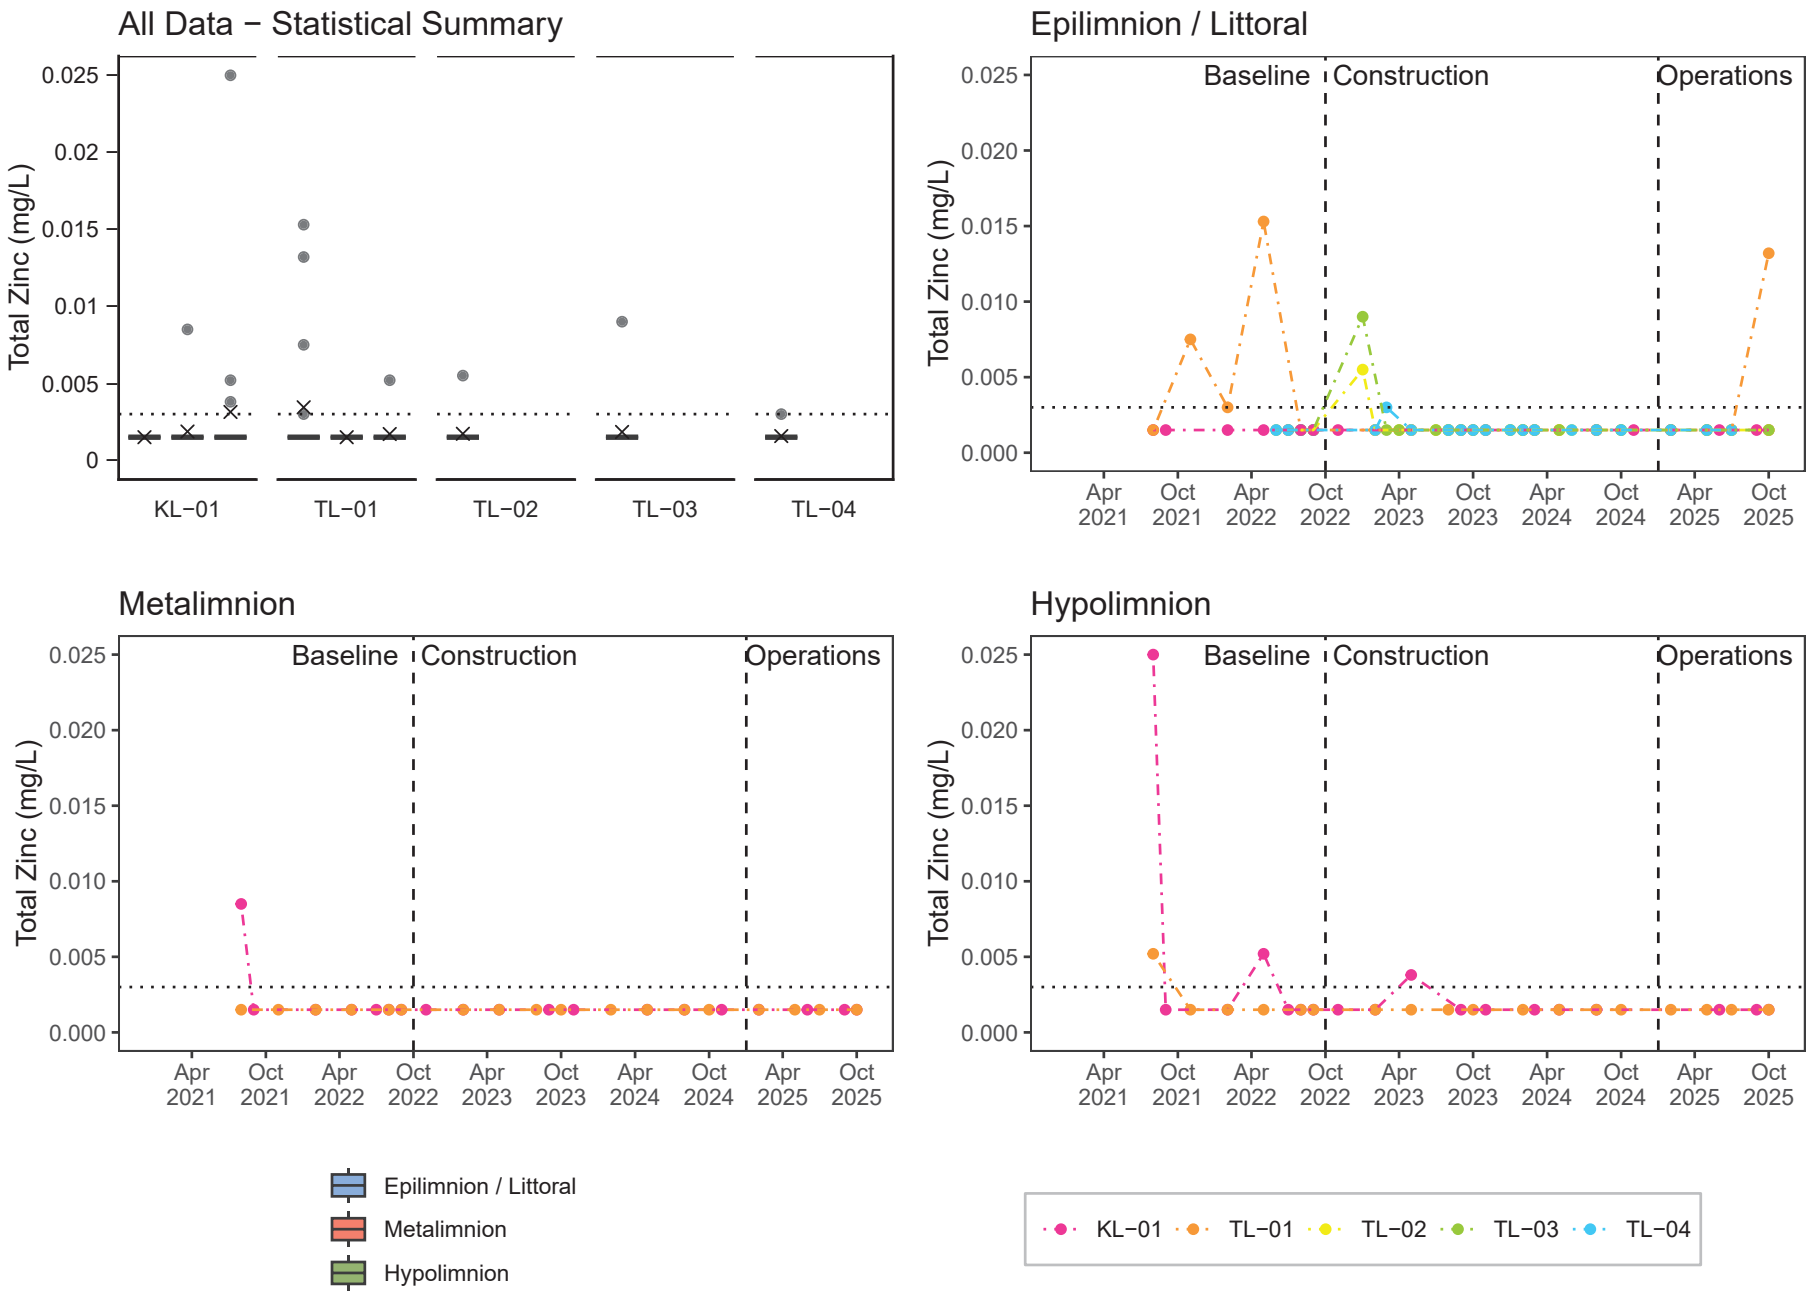
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.
BC WQG−AL working long−term guideline for total uranium is 0.0085 mg/L.

Figure A9−53: Total Uranium in AEMP Monitored Lakes, 2021 to 2025



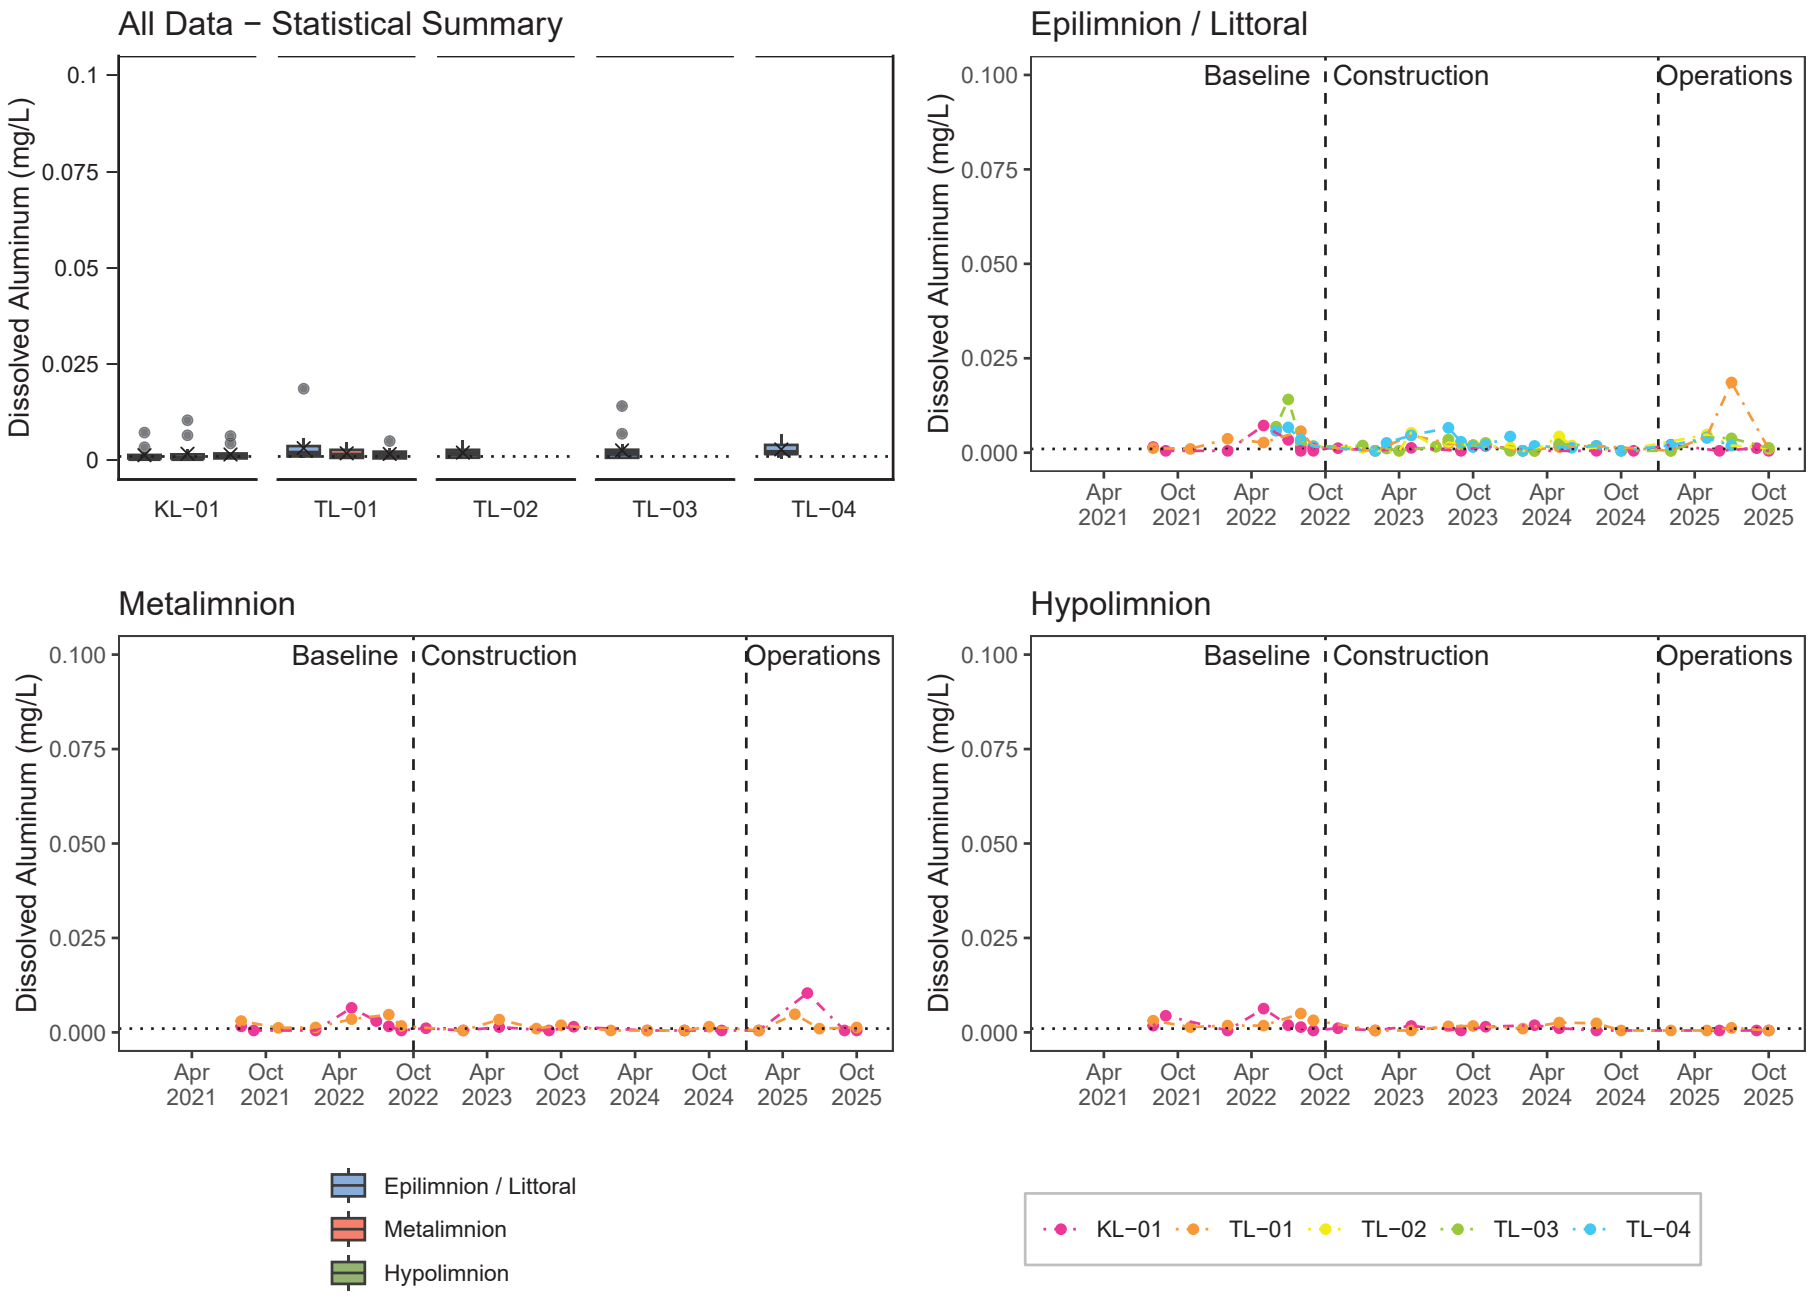
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−54: Total Vanadium in AEMP Monitored Lakes, 2021 to 2025



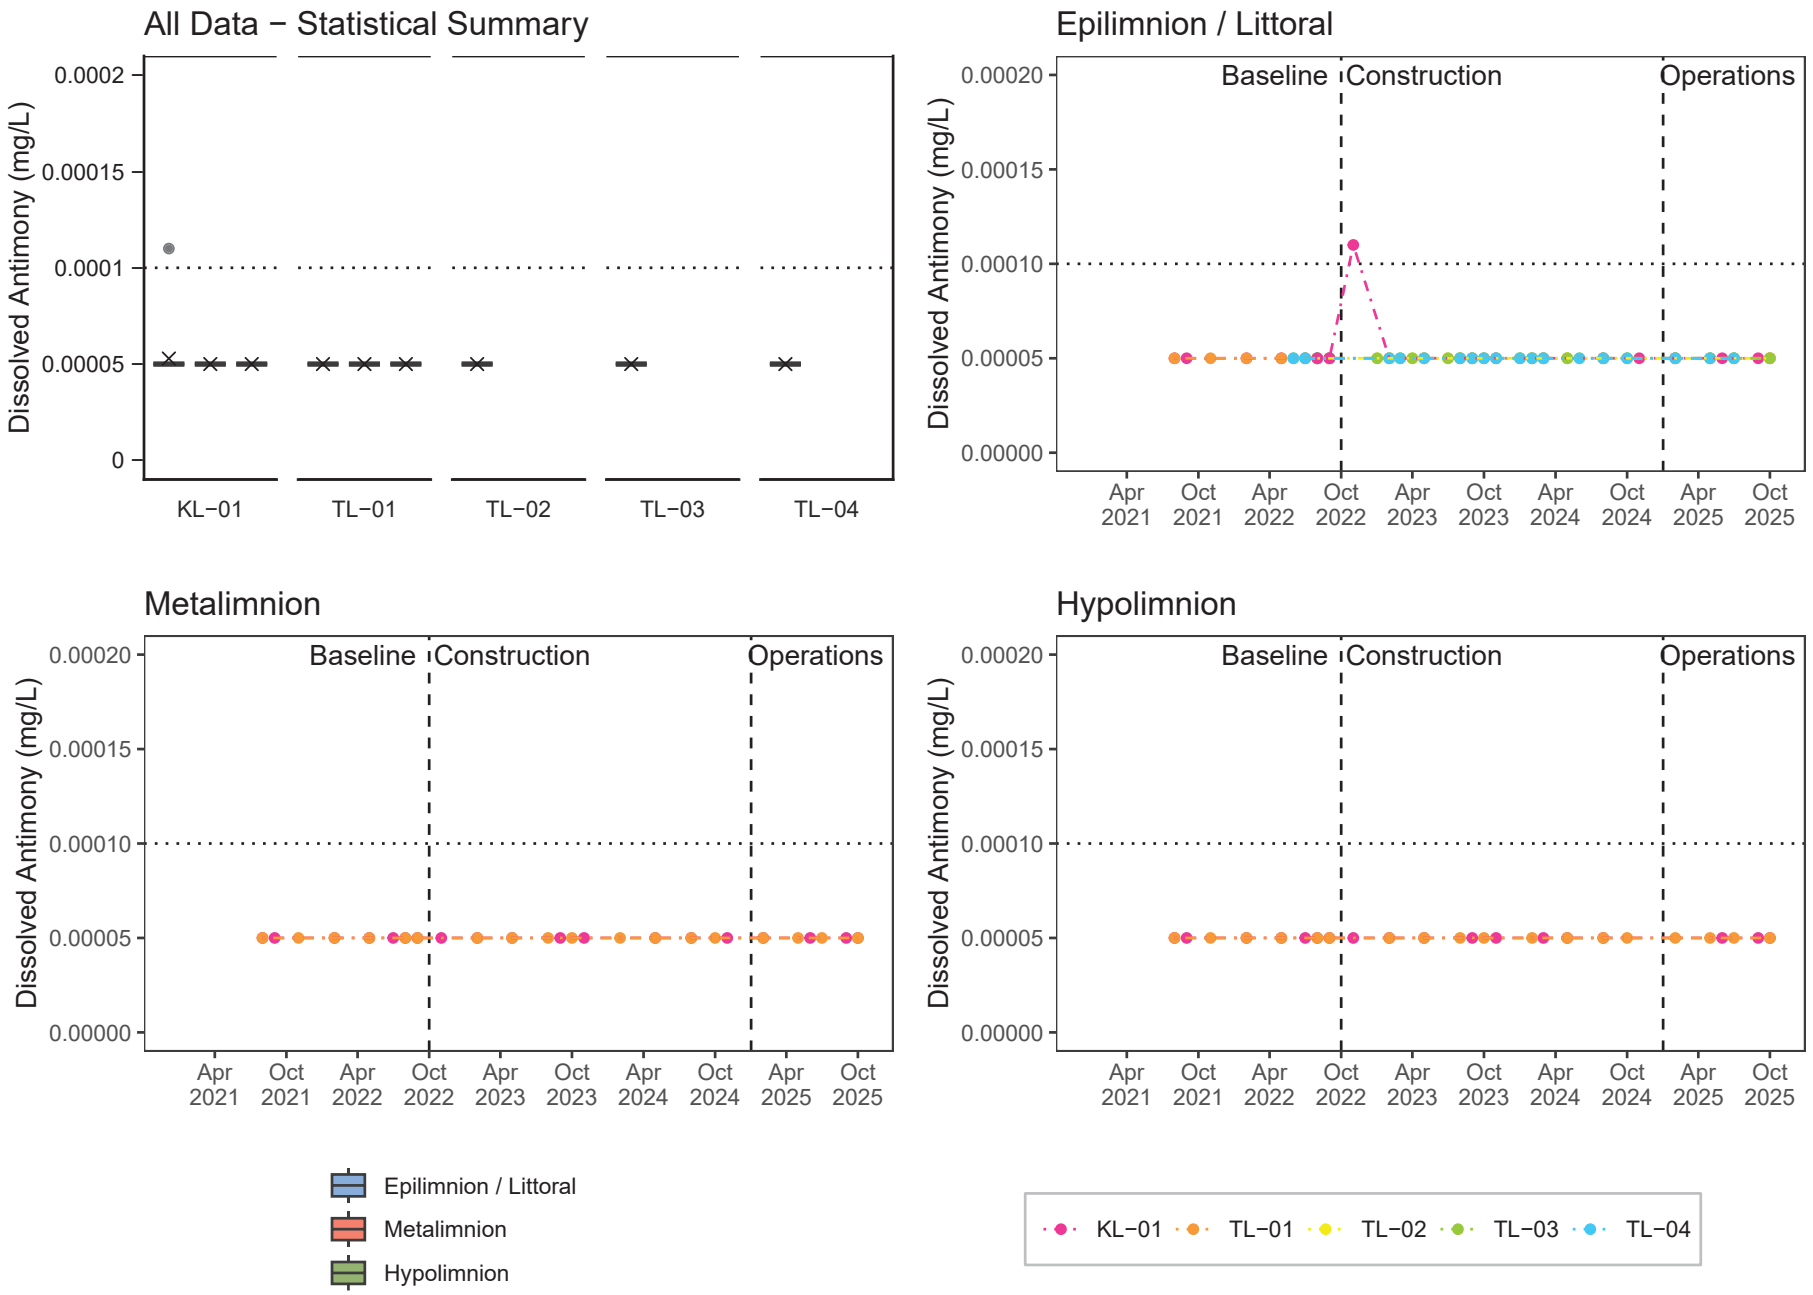
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−55: Total Zinc in AEMP Monitored Lakes, 2021 to 2025



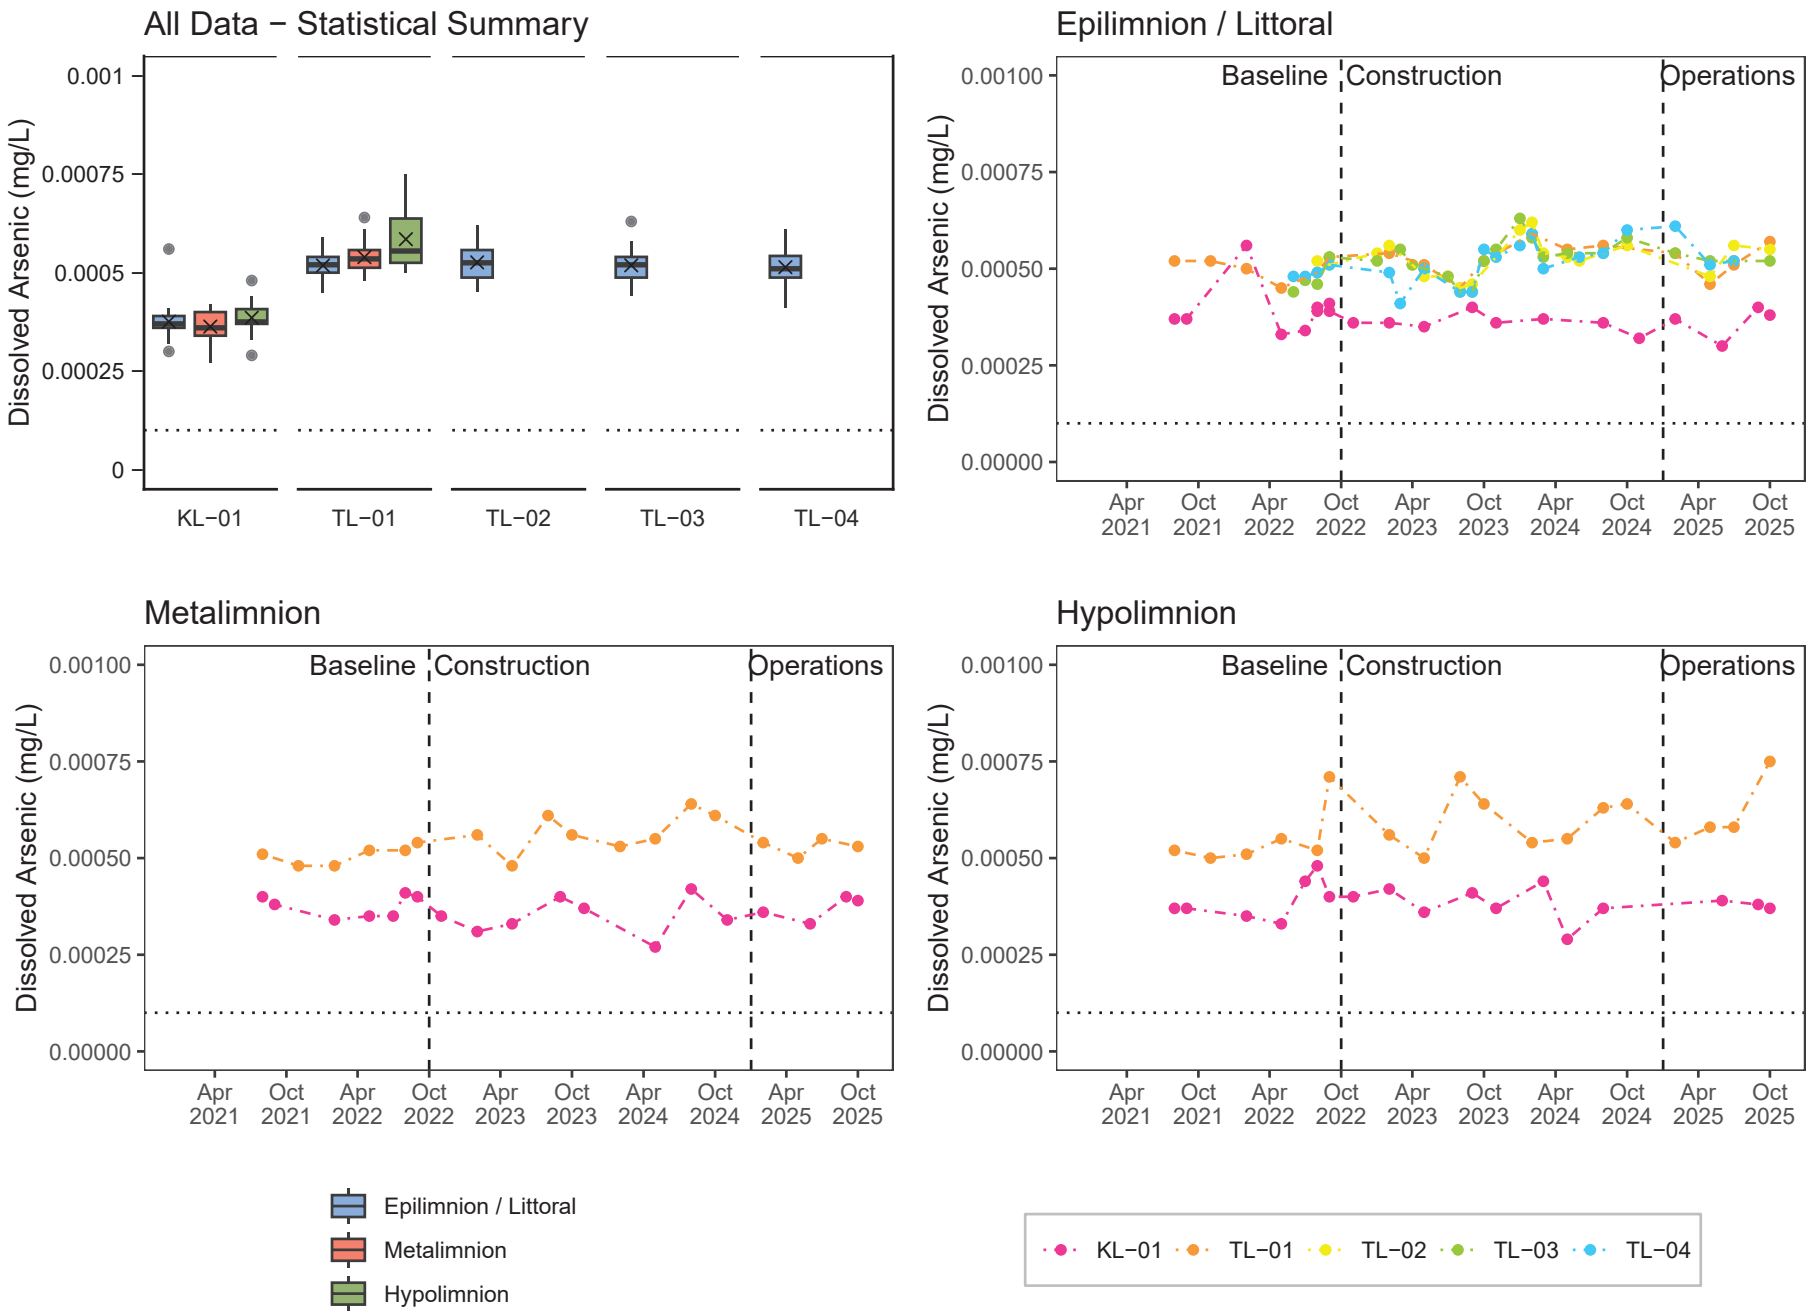
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−56: Dissolved Aluminum in AEMP Monitored Lakes, 2021 to 2025



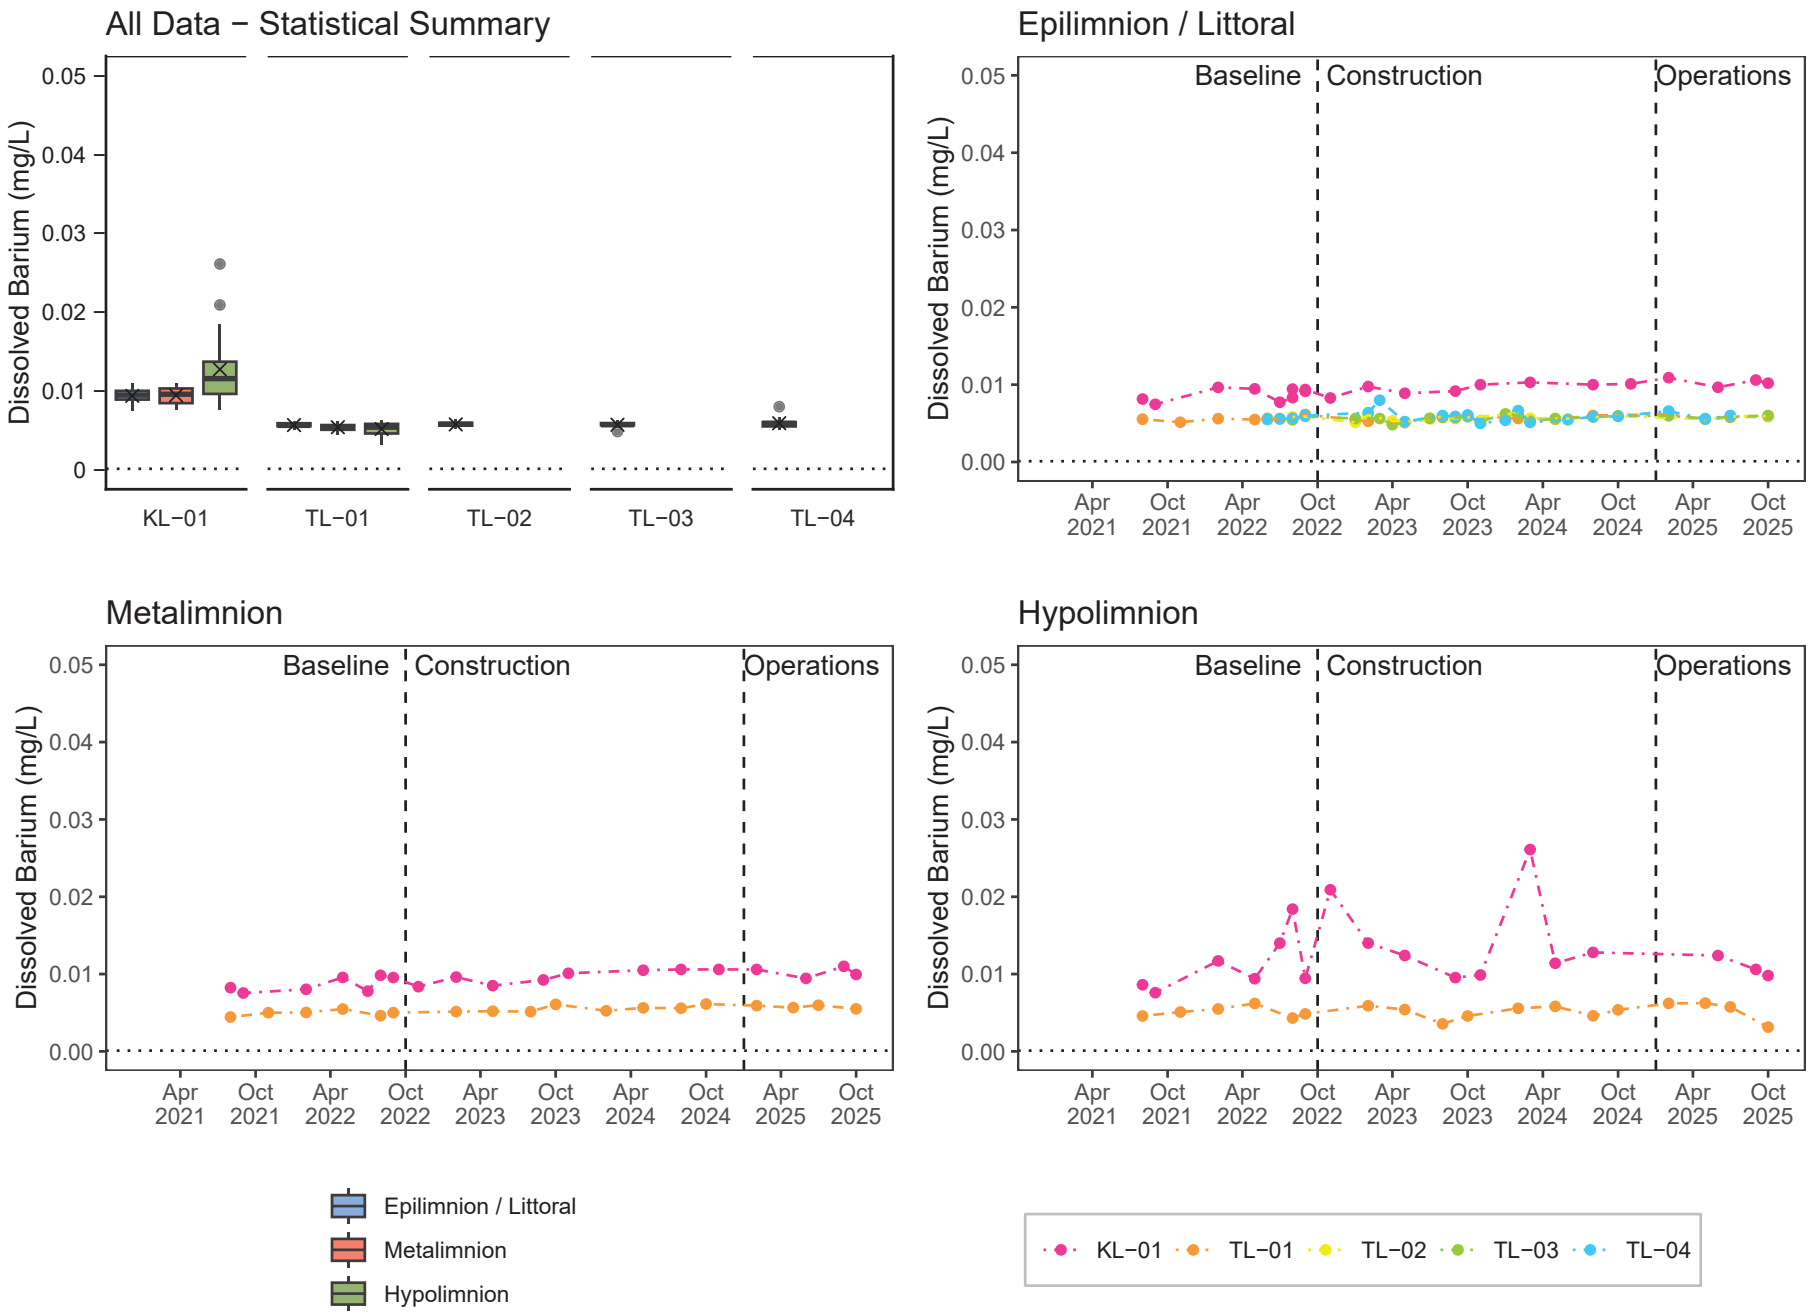
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−57: Dissolved Antimony in AEMP Monitored Lakes, 2021 to 2025



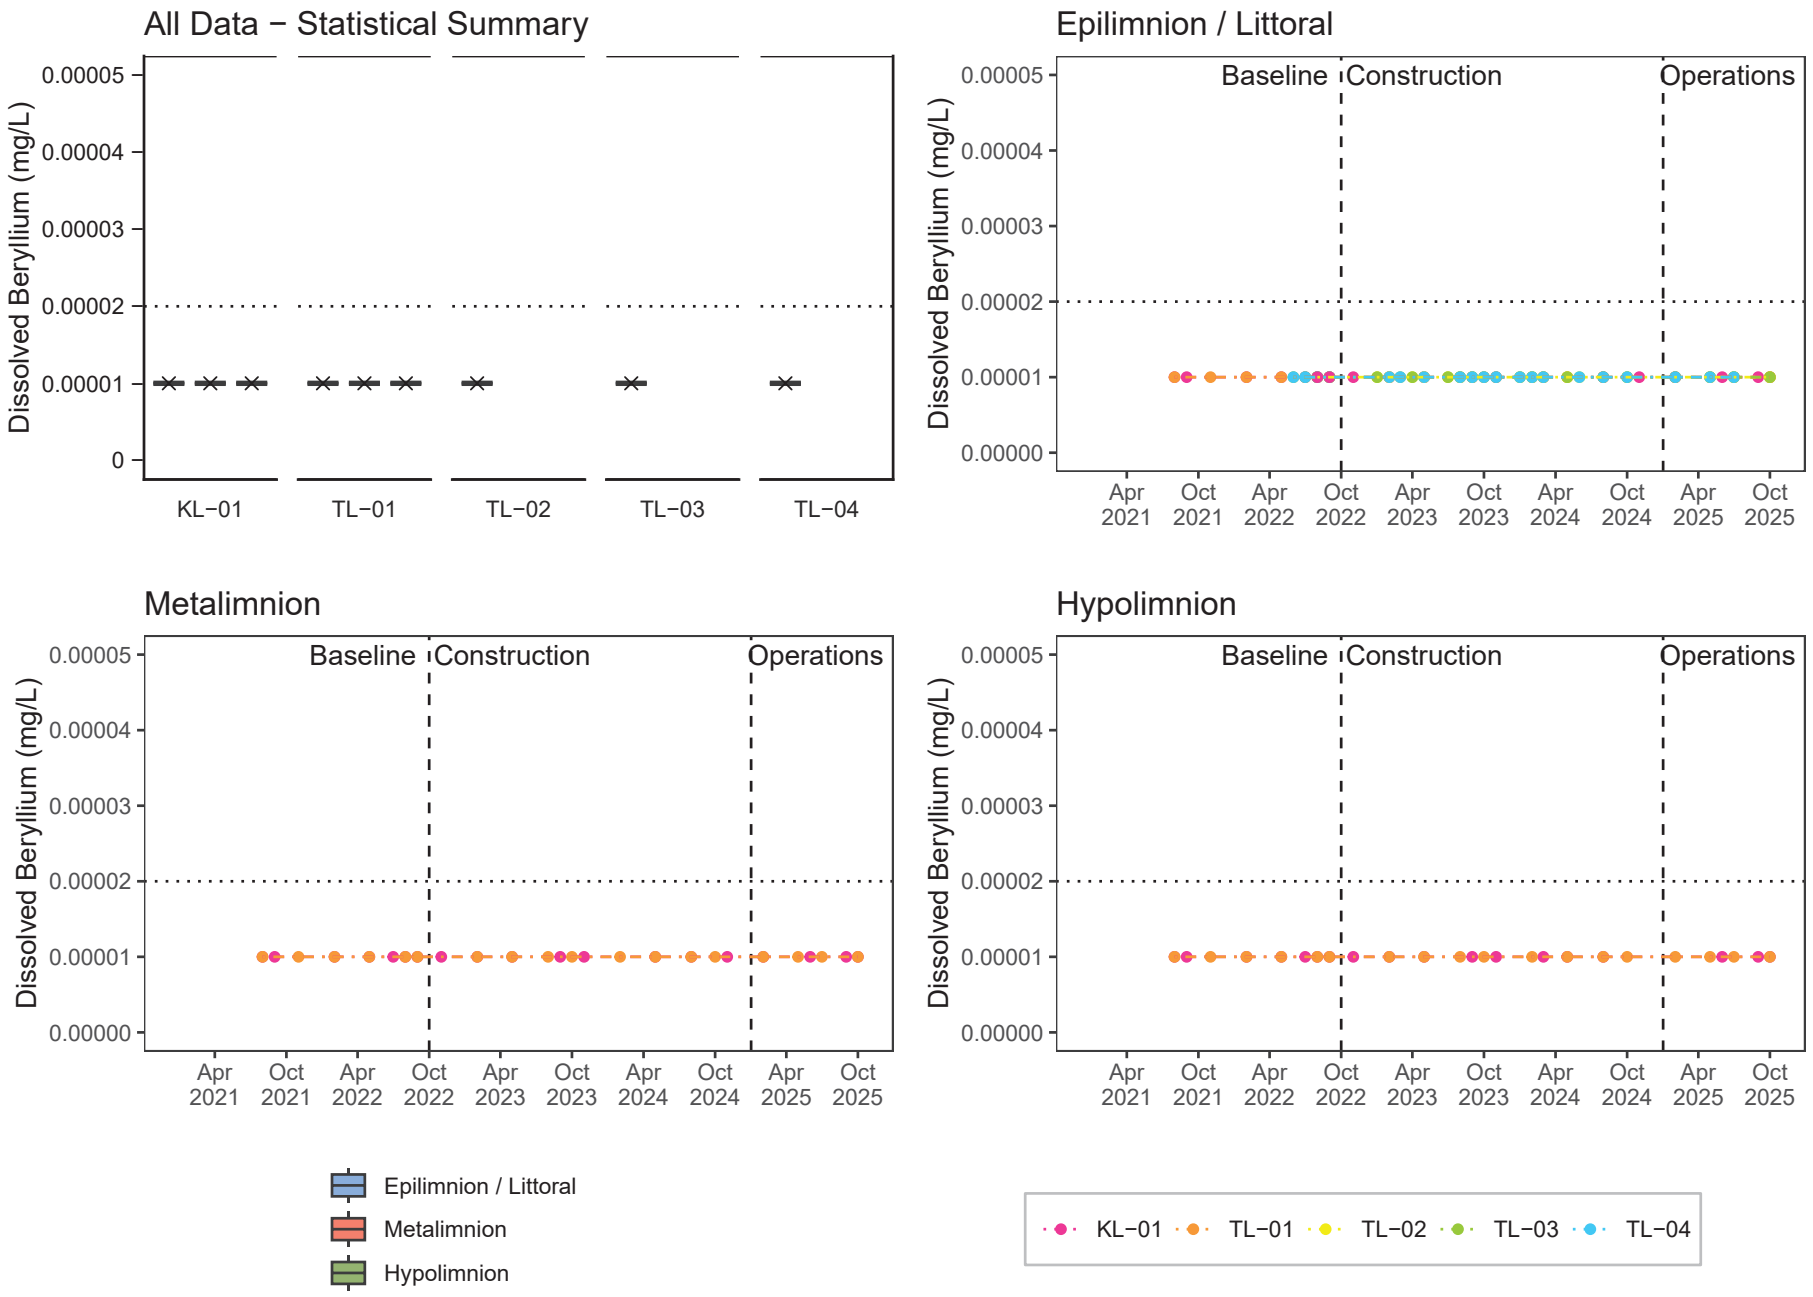
Notes: Dashed line indicates minimum detection limits.

Figure A9−58: Dissolved Arsenic in AEMP Monitored Lakes, 2021 to 2025



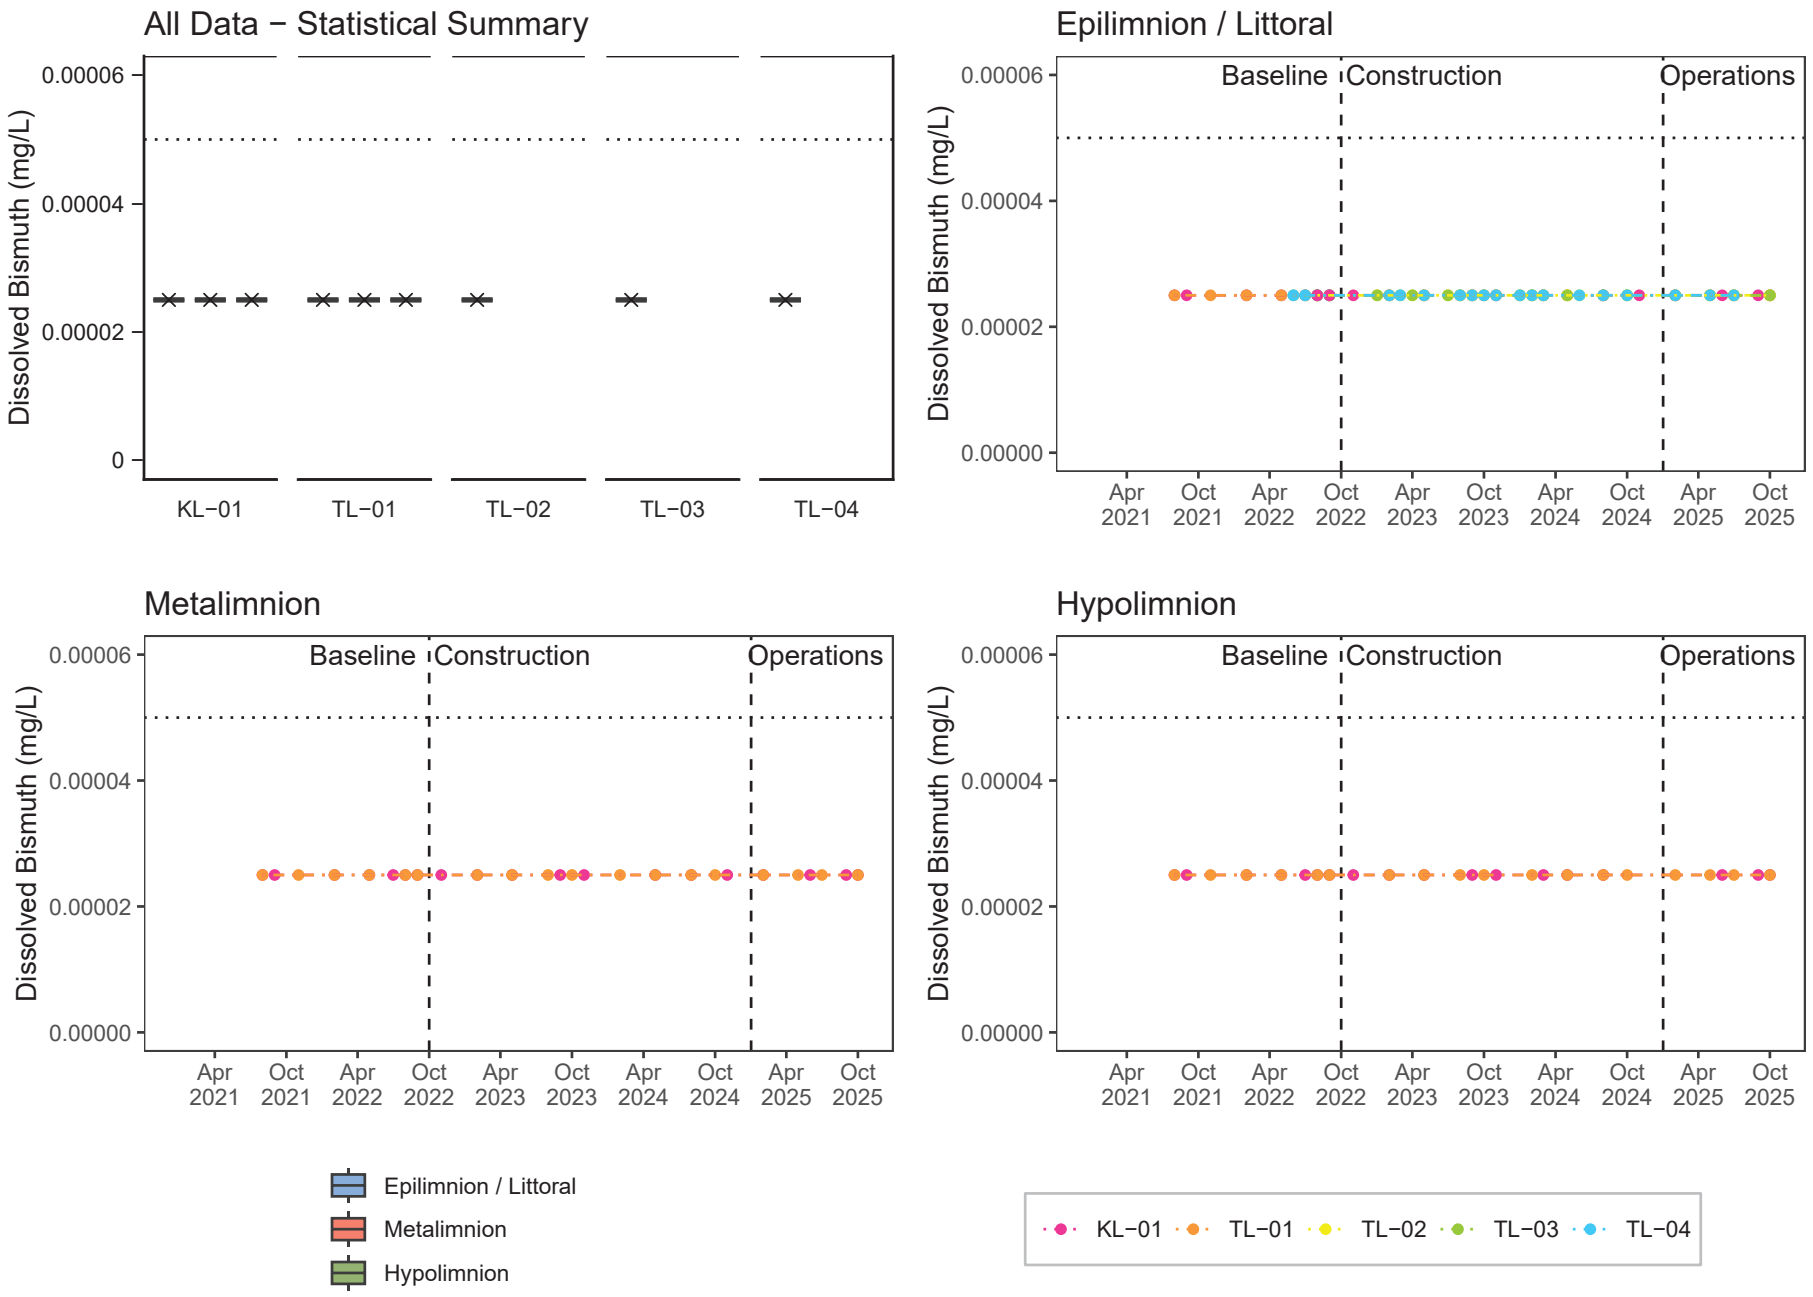
Notes: Dashed line indicates minimum detection limits.

Figure A9−59: Dissolved Barium in AEMP Monitored Lakes, 2021 to 2025



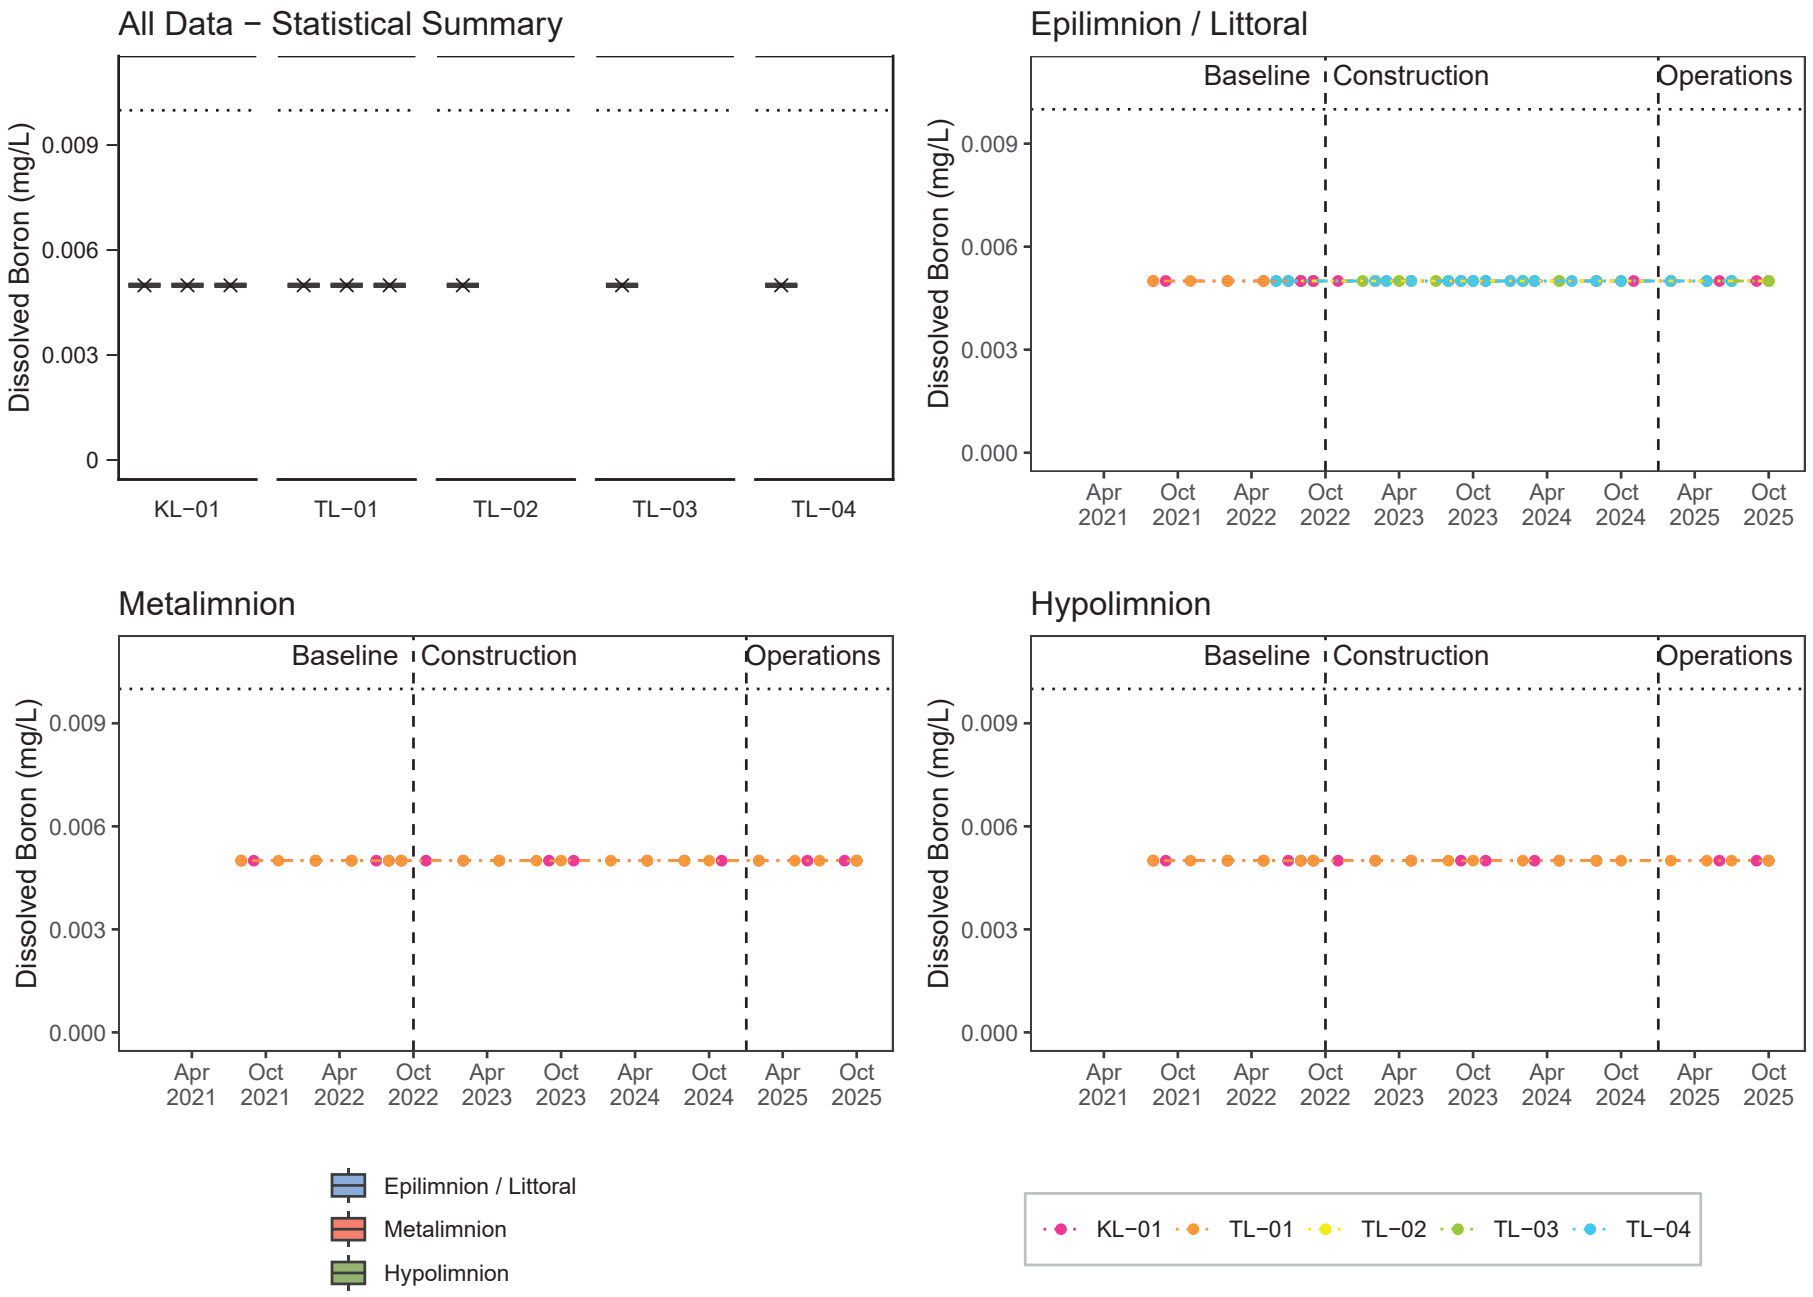
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−60: Dissolved Beryllium in AEMP Monitored Lakes, 2021 to 2025



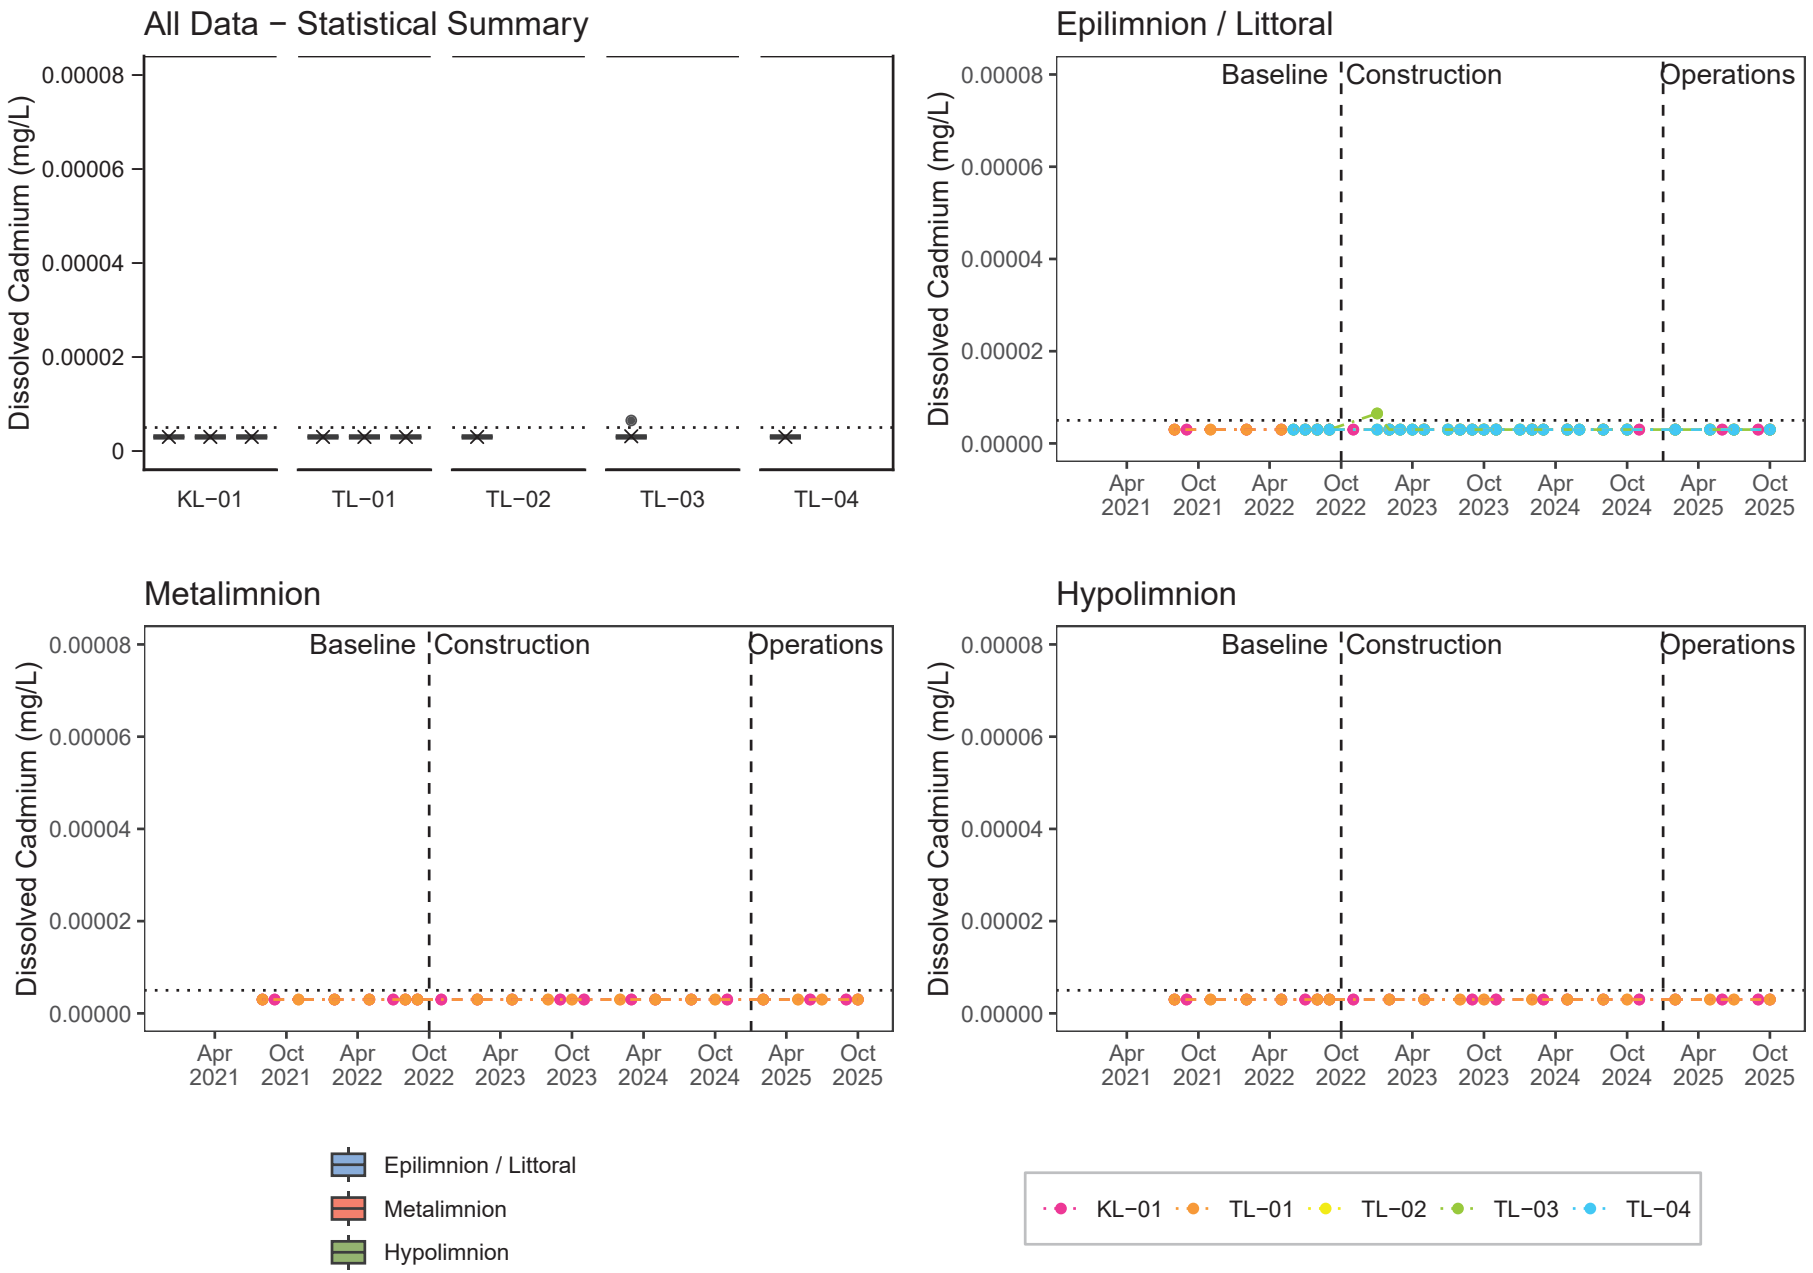
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−61: Dissolved Bismuth in AEMP Monitored Lakes, 2021 to 2025



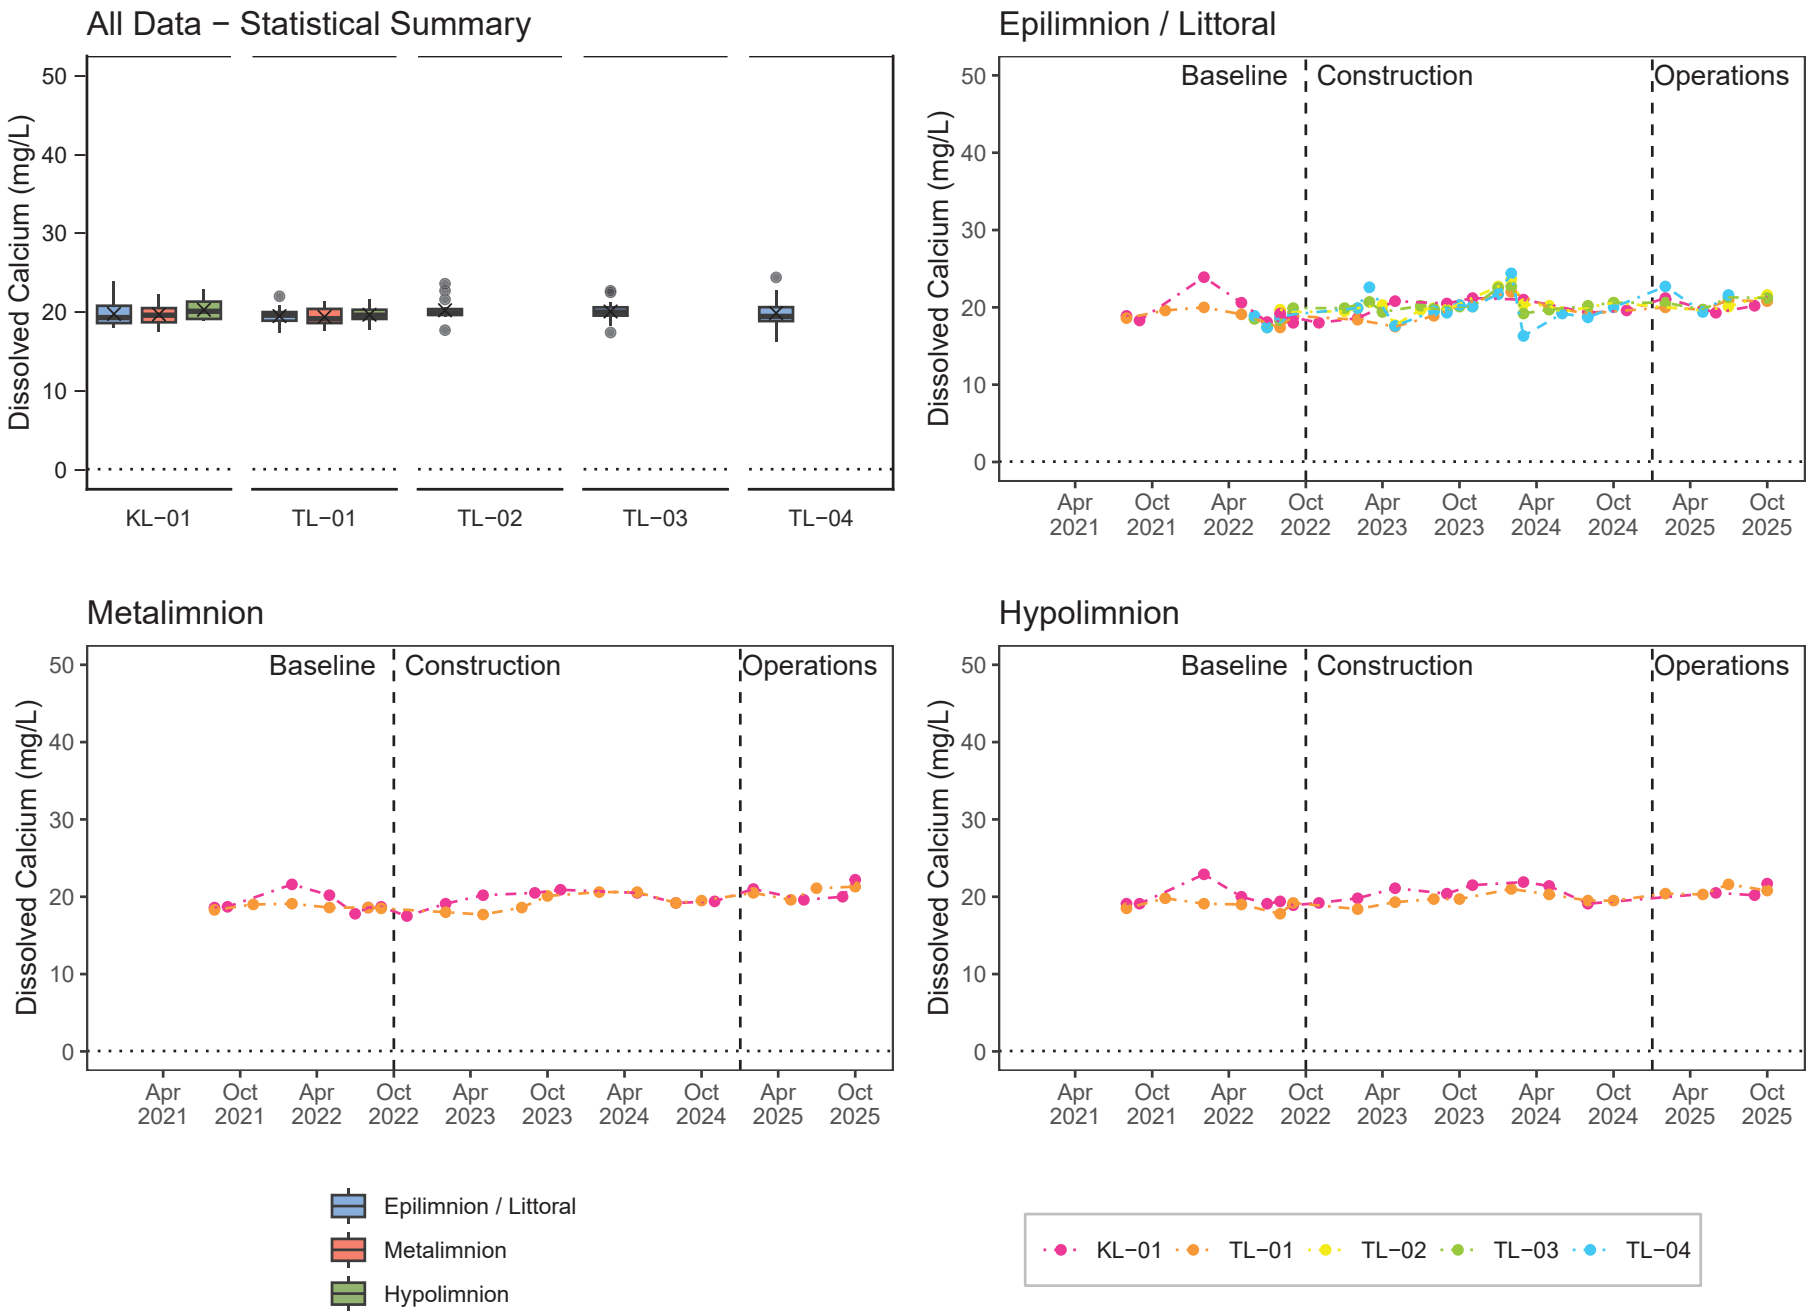
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−62: Dissolved Boron in AEMP Monitored Lakes, 2021 to 2025



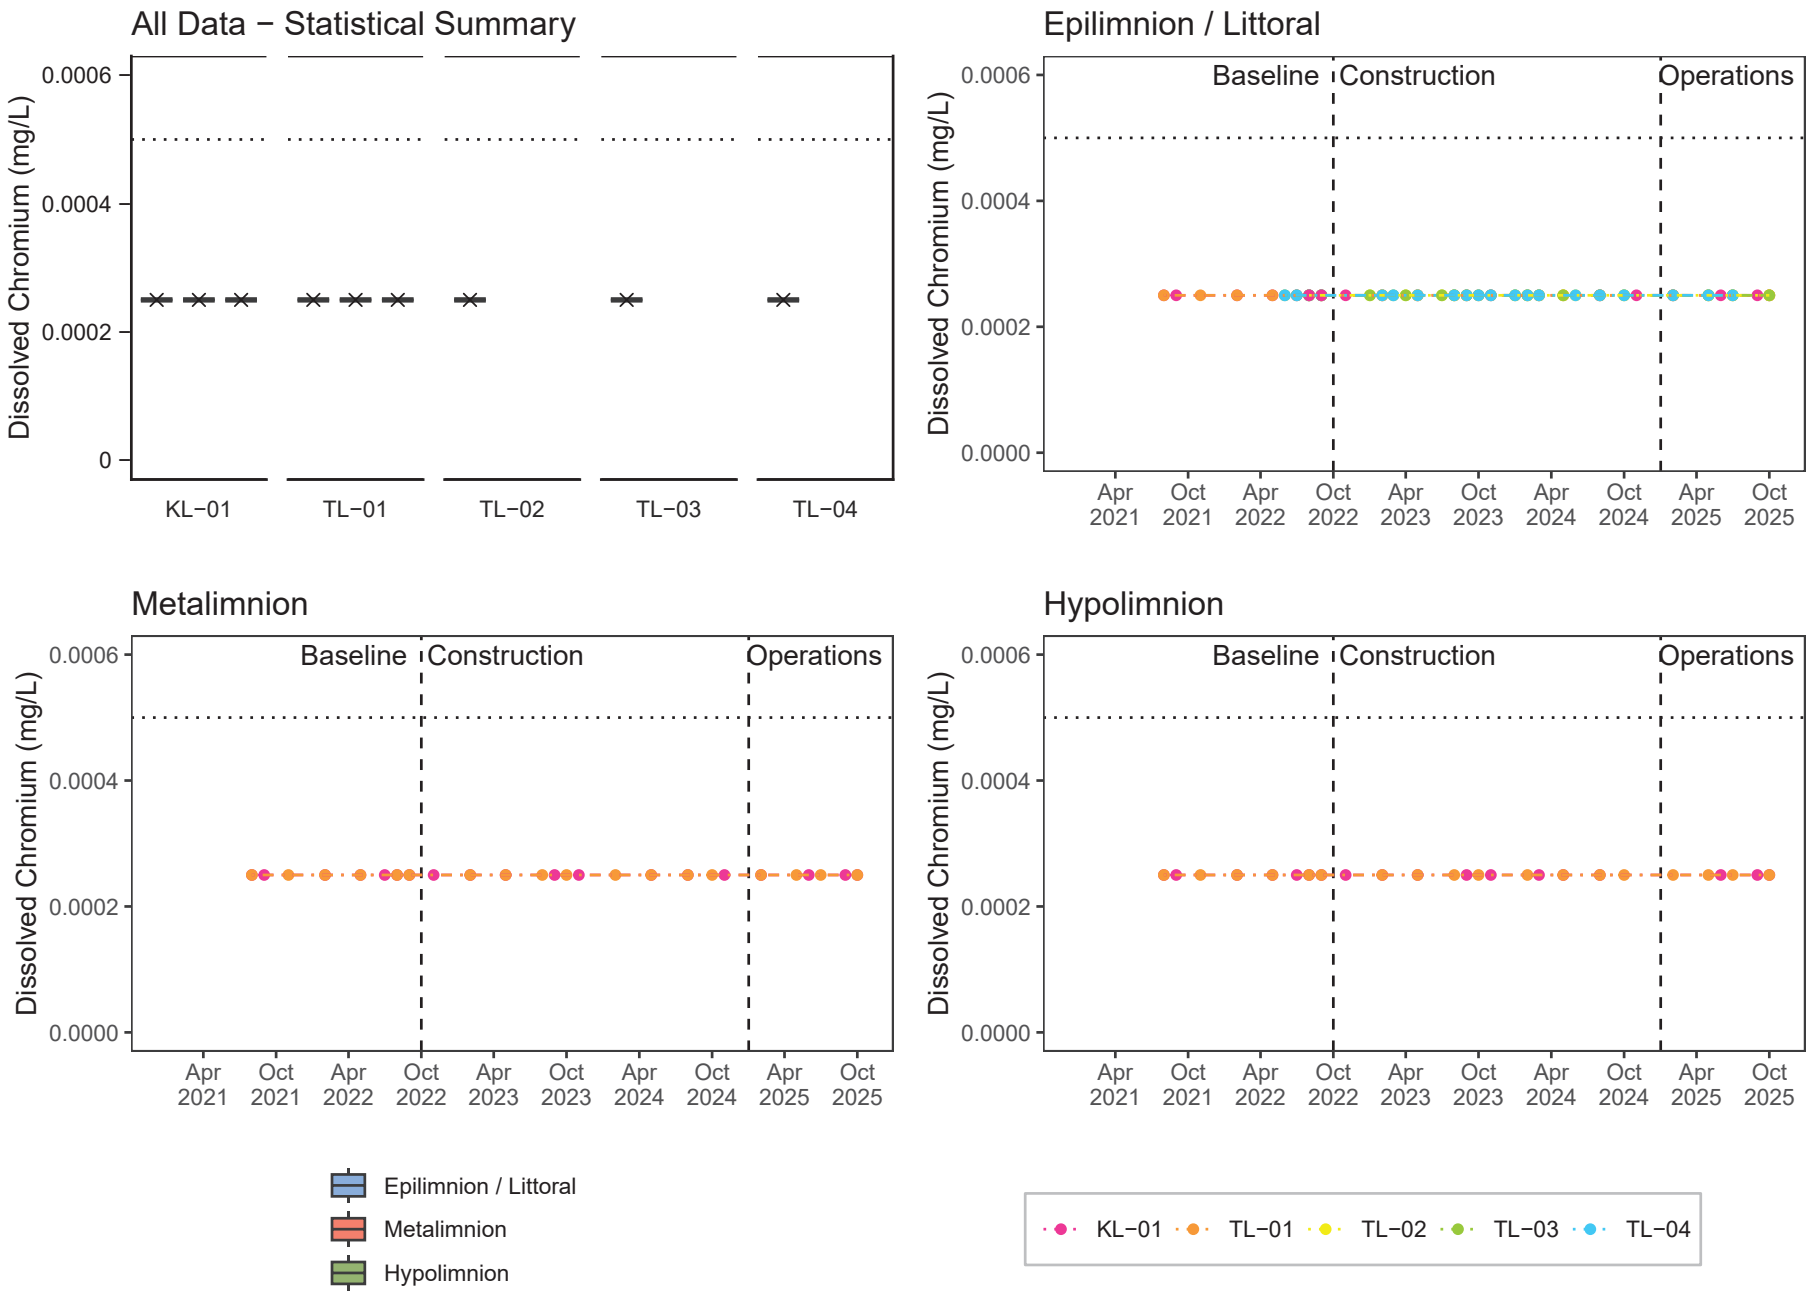
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.
Median BC WQG−AL long−term chronic guideline for dissolved cadmium for Project lakes is 0.00016 mg/L.

Figure A9−63: Dissolved Cadmium in AEMP Monitored Lakes, 2021 to 2025



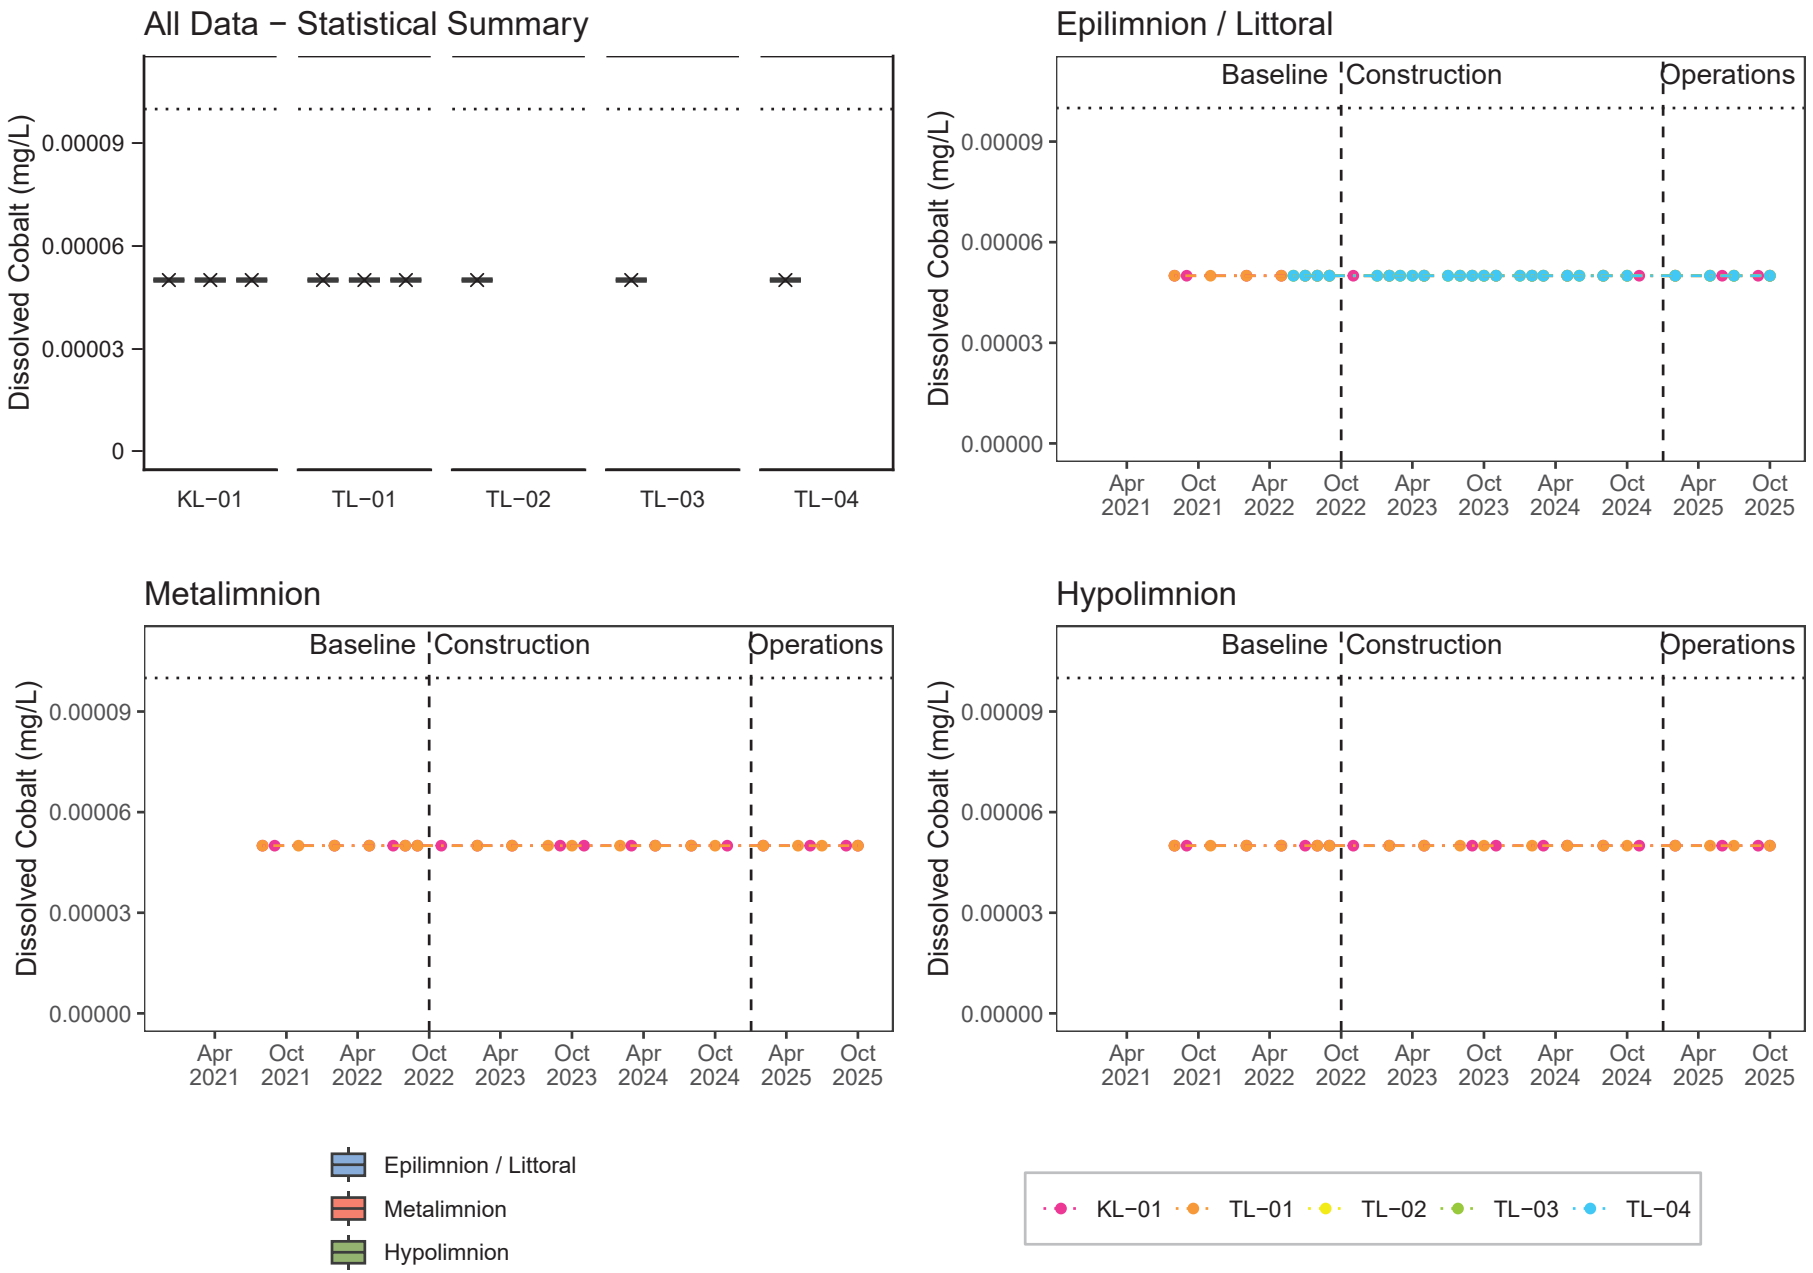
Notes: Dashed line indicates minimum detection limits.

Figure A9−64: Dissolved Calcium in AEMP Monitored Lakes, 2021 to 2025



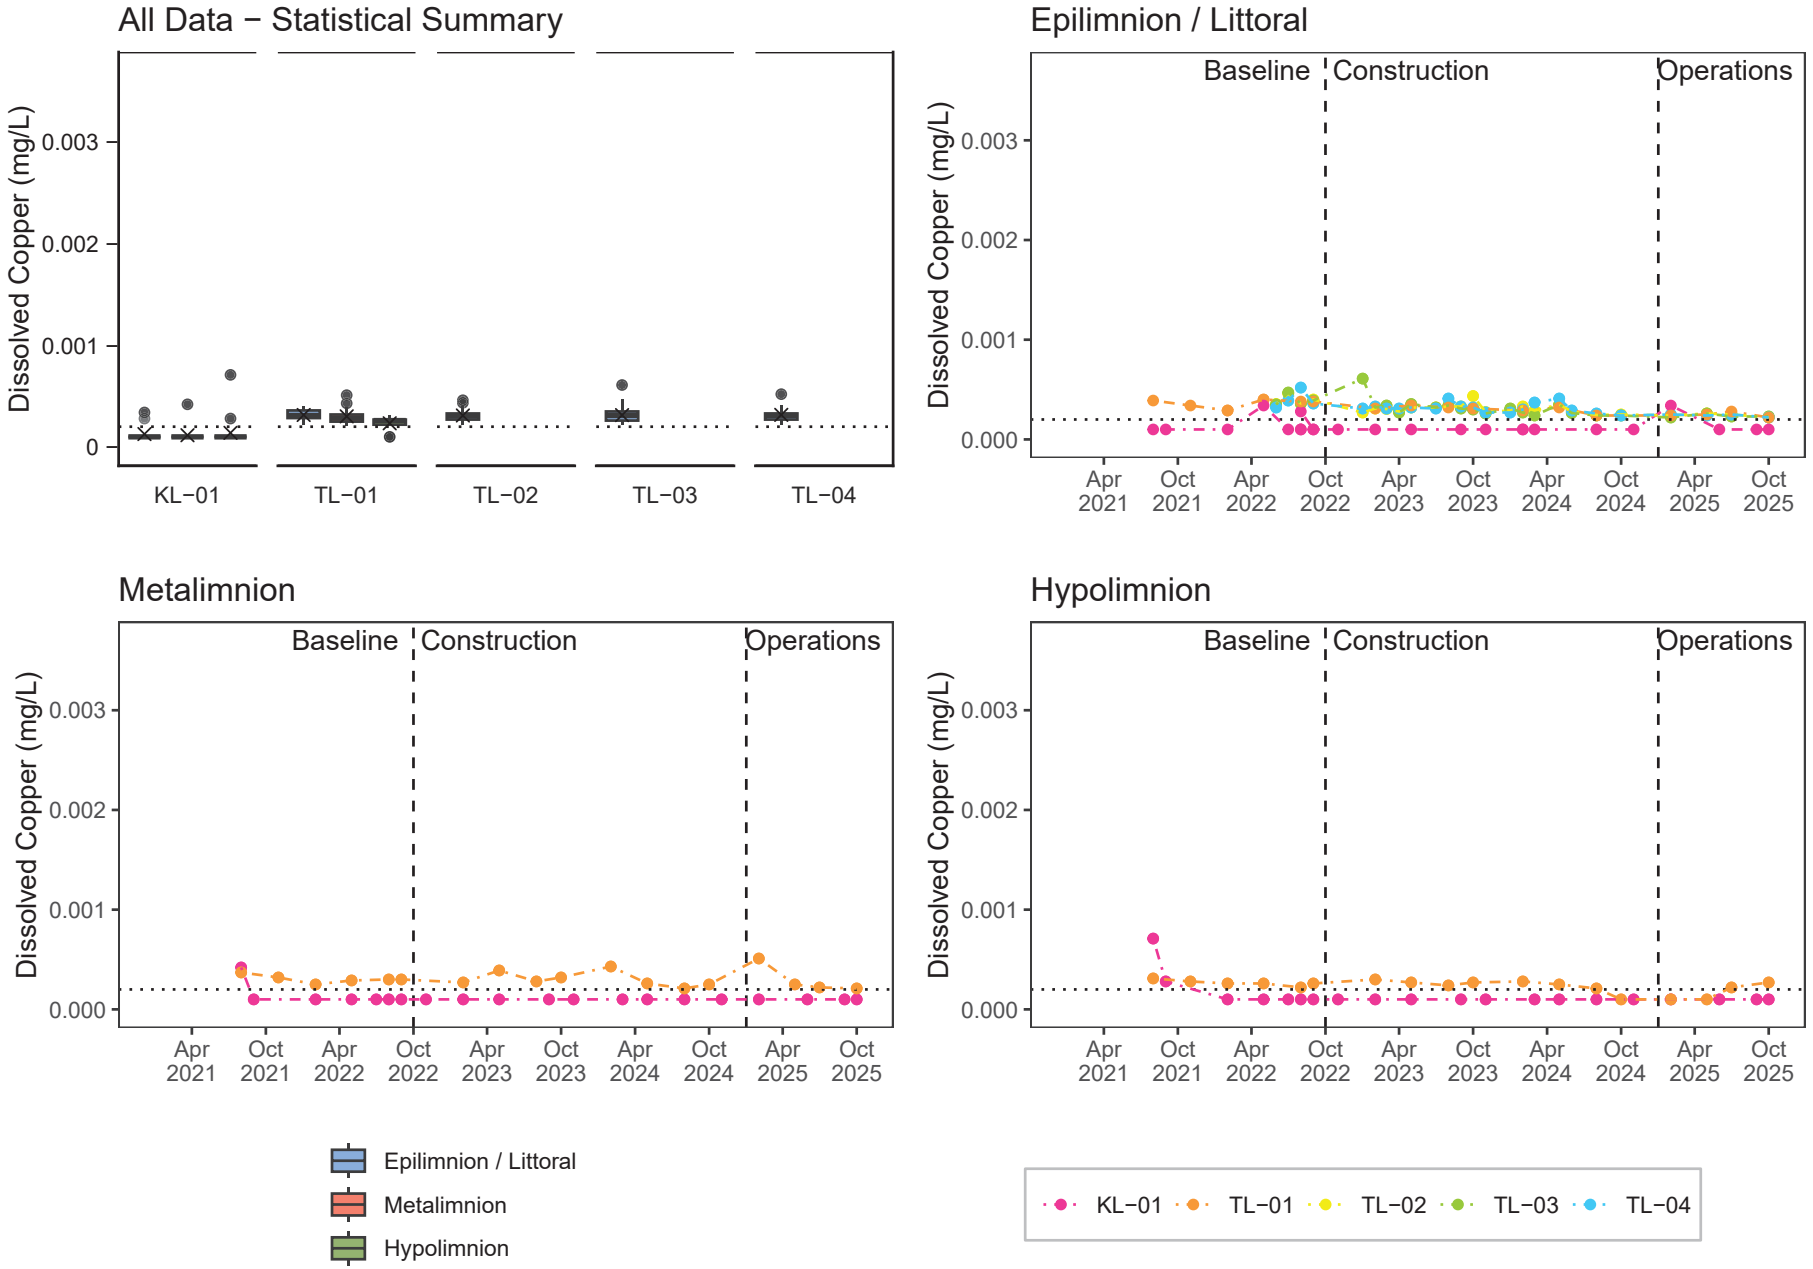
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−65: Dissolved Chromium in AEMP Monitored Lakes, 2021 to 2025



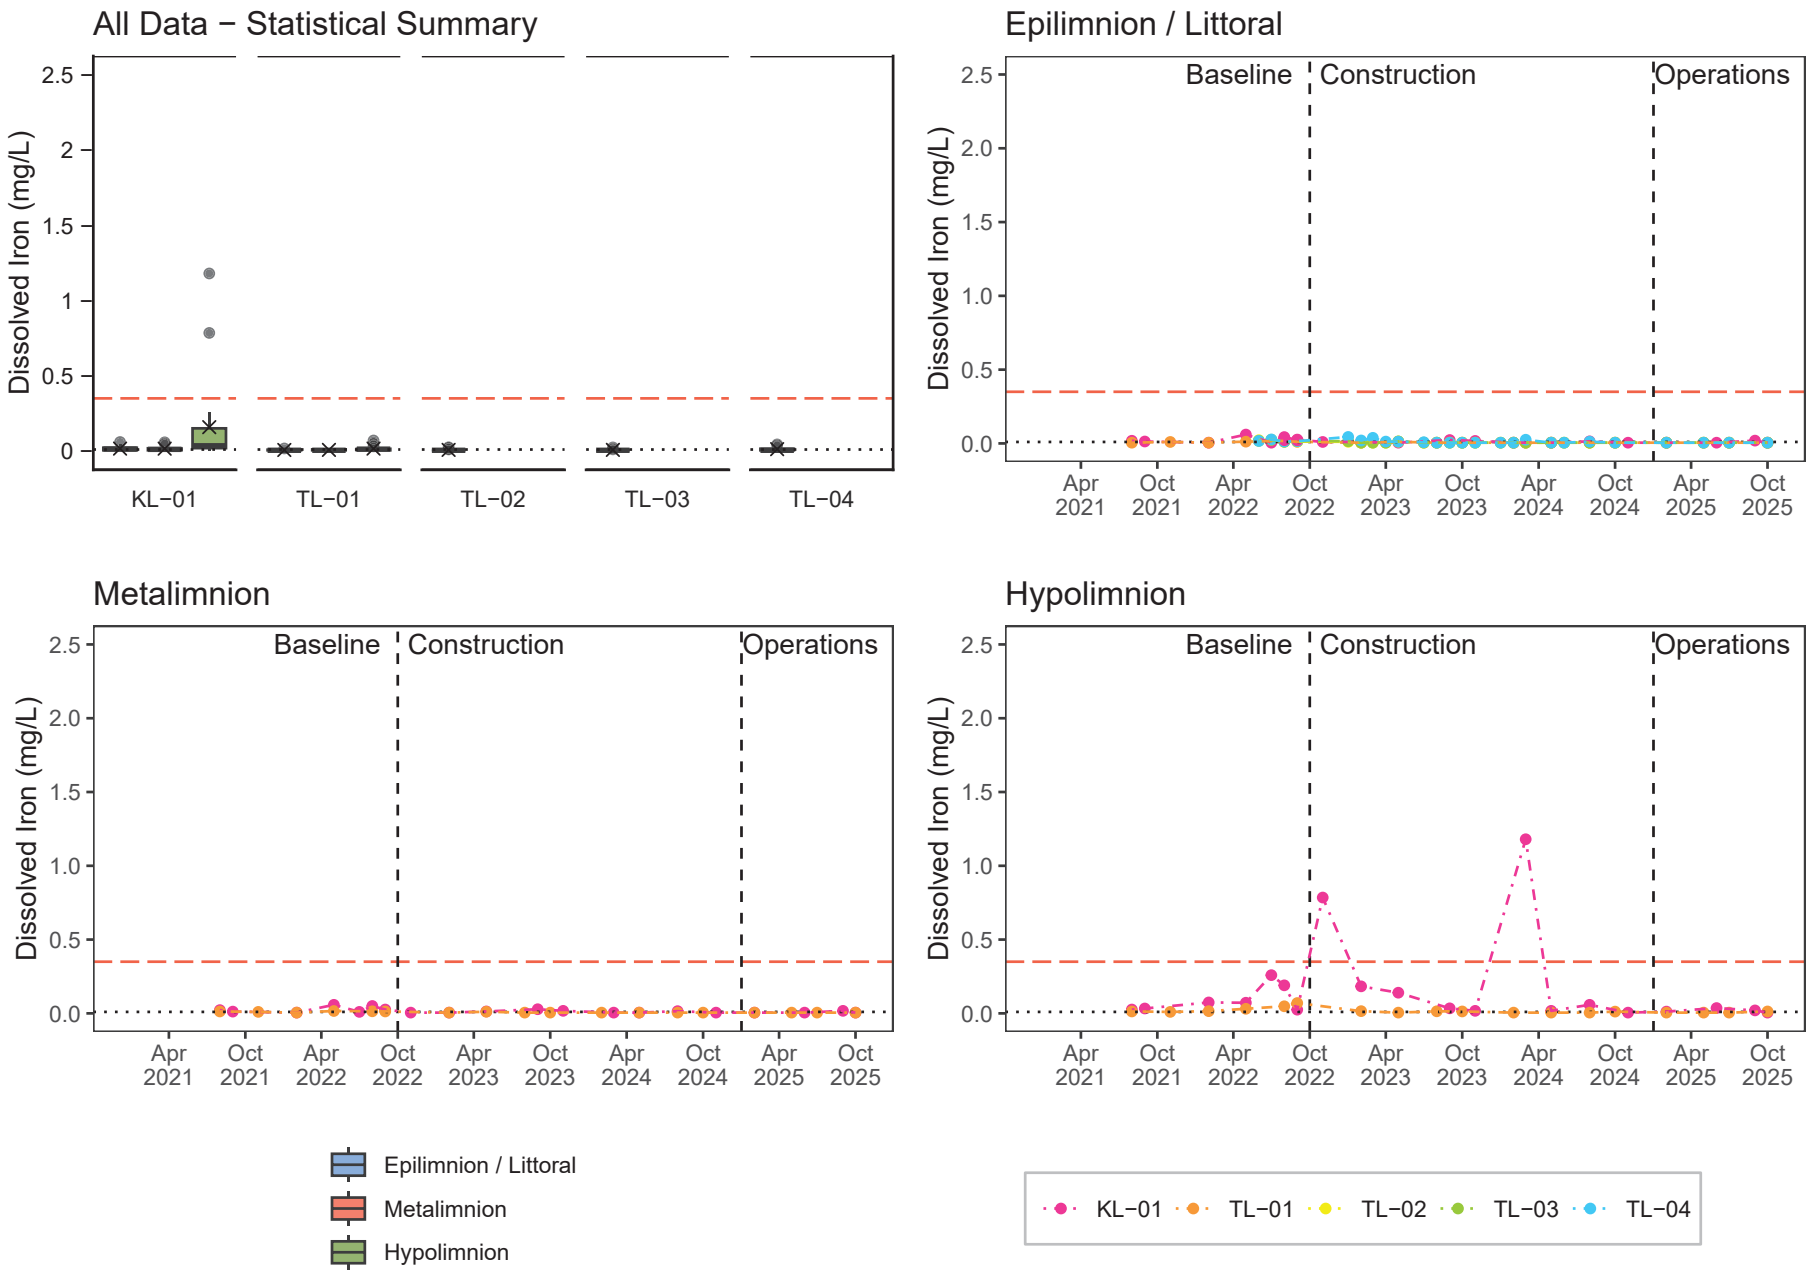
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.
BC WQG−AL long−term 30−day guideline for dissolved cobalt is 0.000441 mg/L.

Figure A9−66: Dissolved Cobalt in AEMP Monitored Lakes, 2021 to 2025



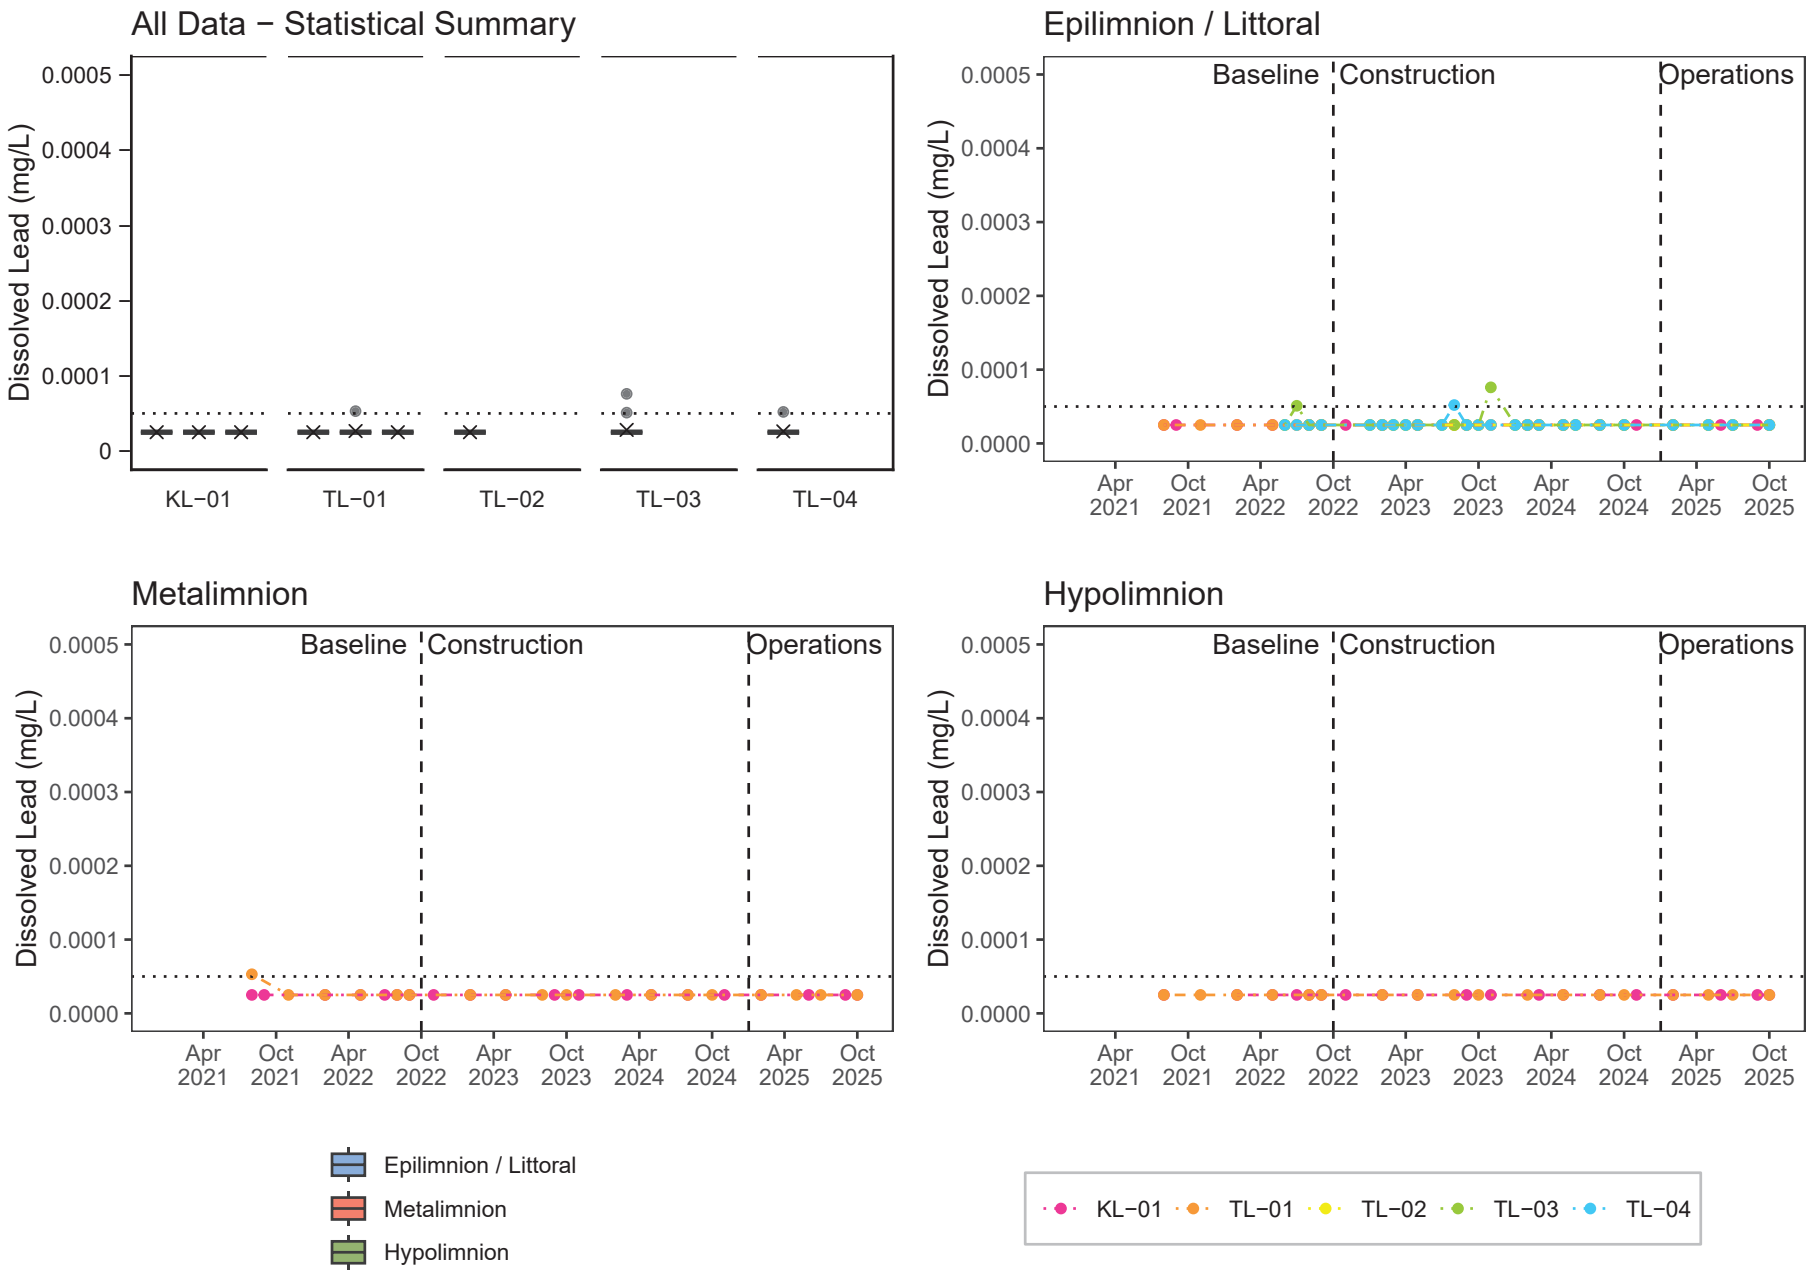
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.
Median BC BLM guideline for dissolved copper for Project lakes is 0.0043 mg/L.

Figure A9−67: Dissolved Copper in AEMP Monitored Lakes, 2021 to 2025



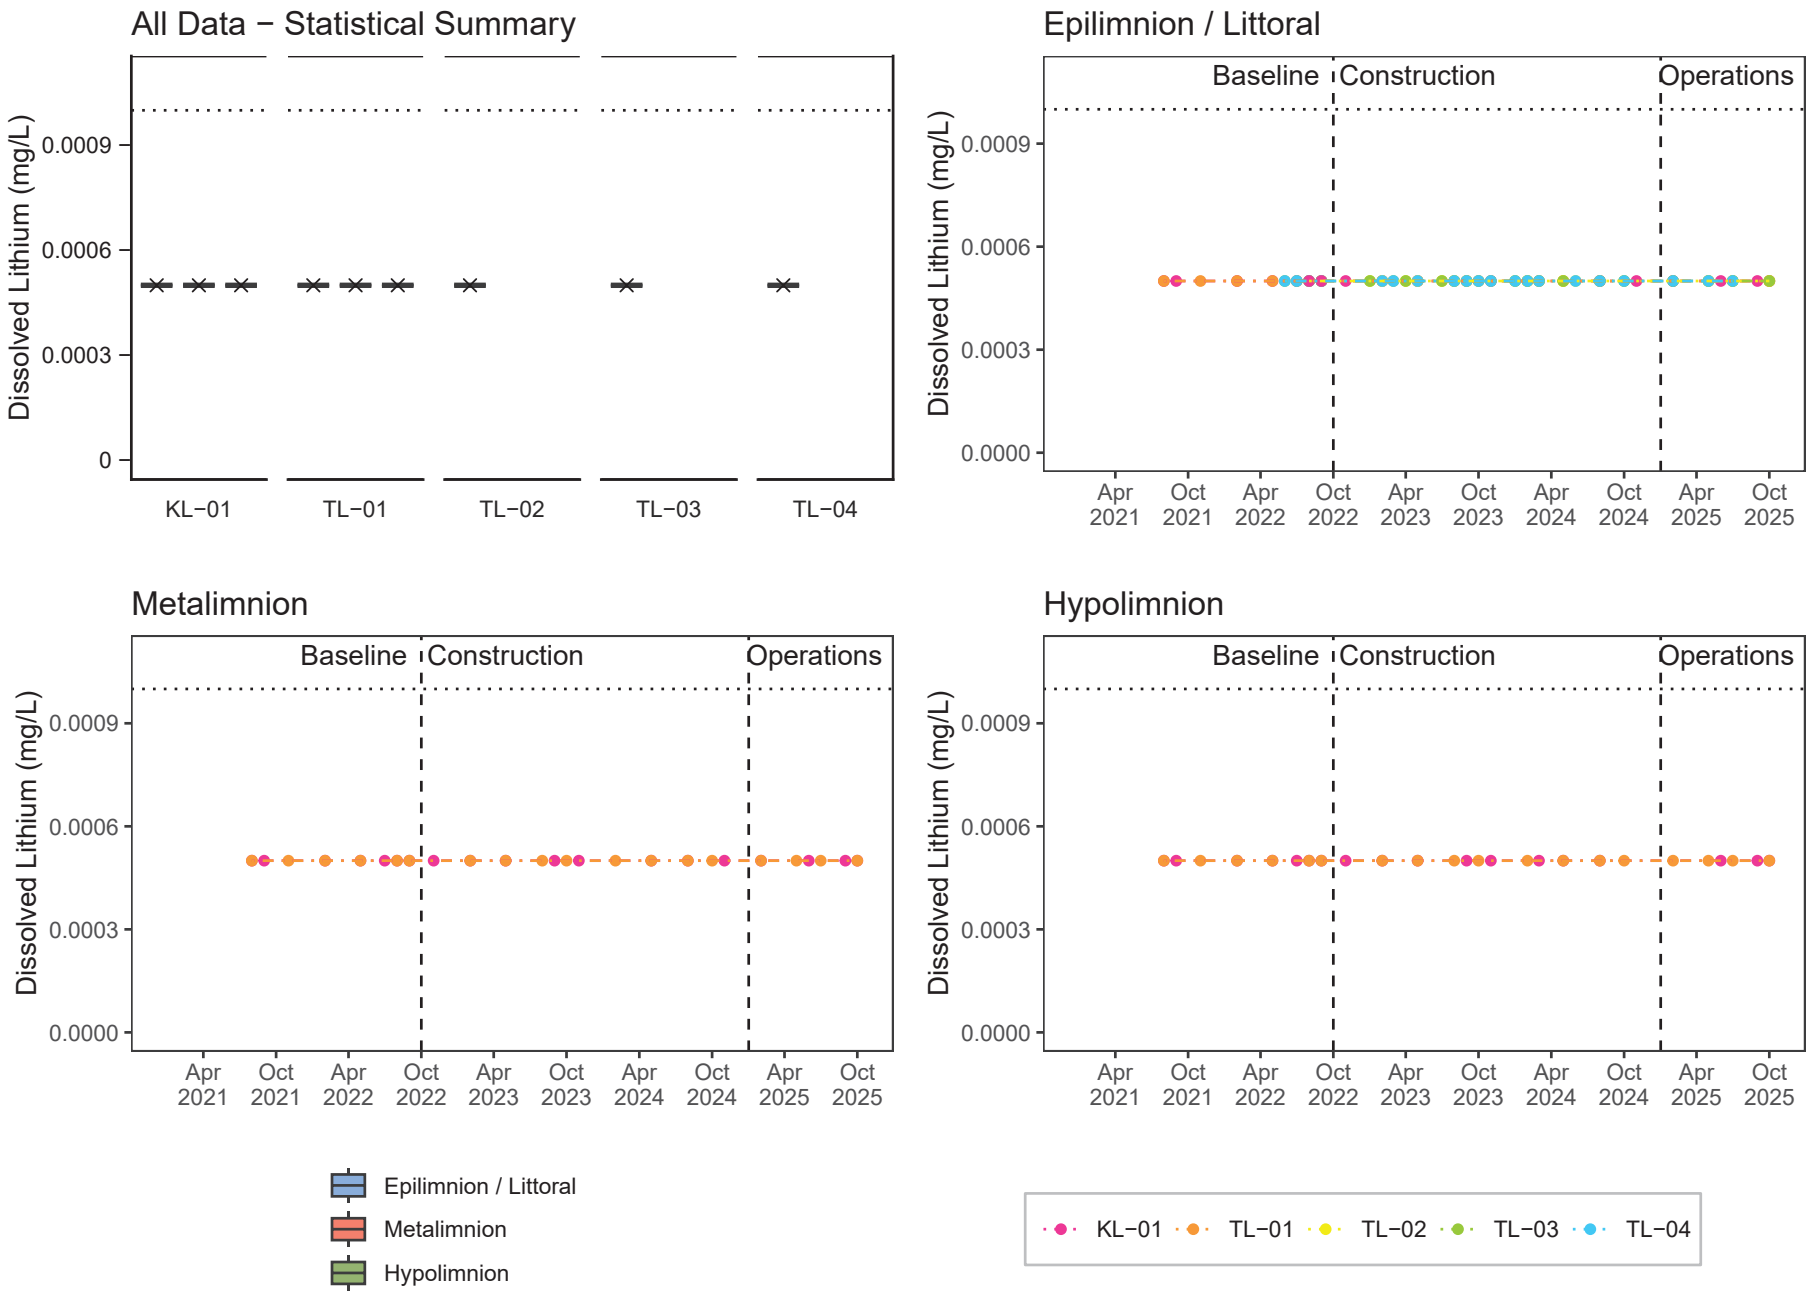
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.
BC WQG−AL short−term guideline for dissolved iron is 0.35 mg/L.

Figure A9−68: Dissolved Iron in AEMP Monitored Lakes, 2021 to 2025



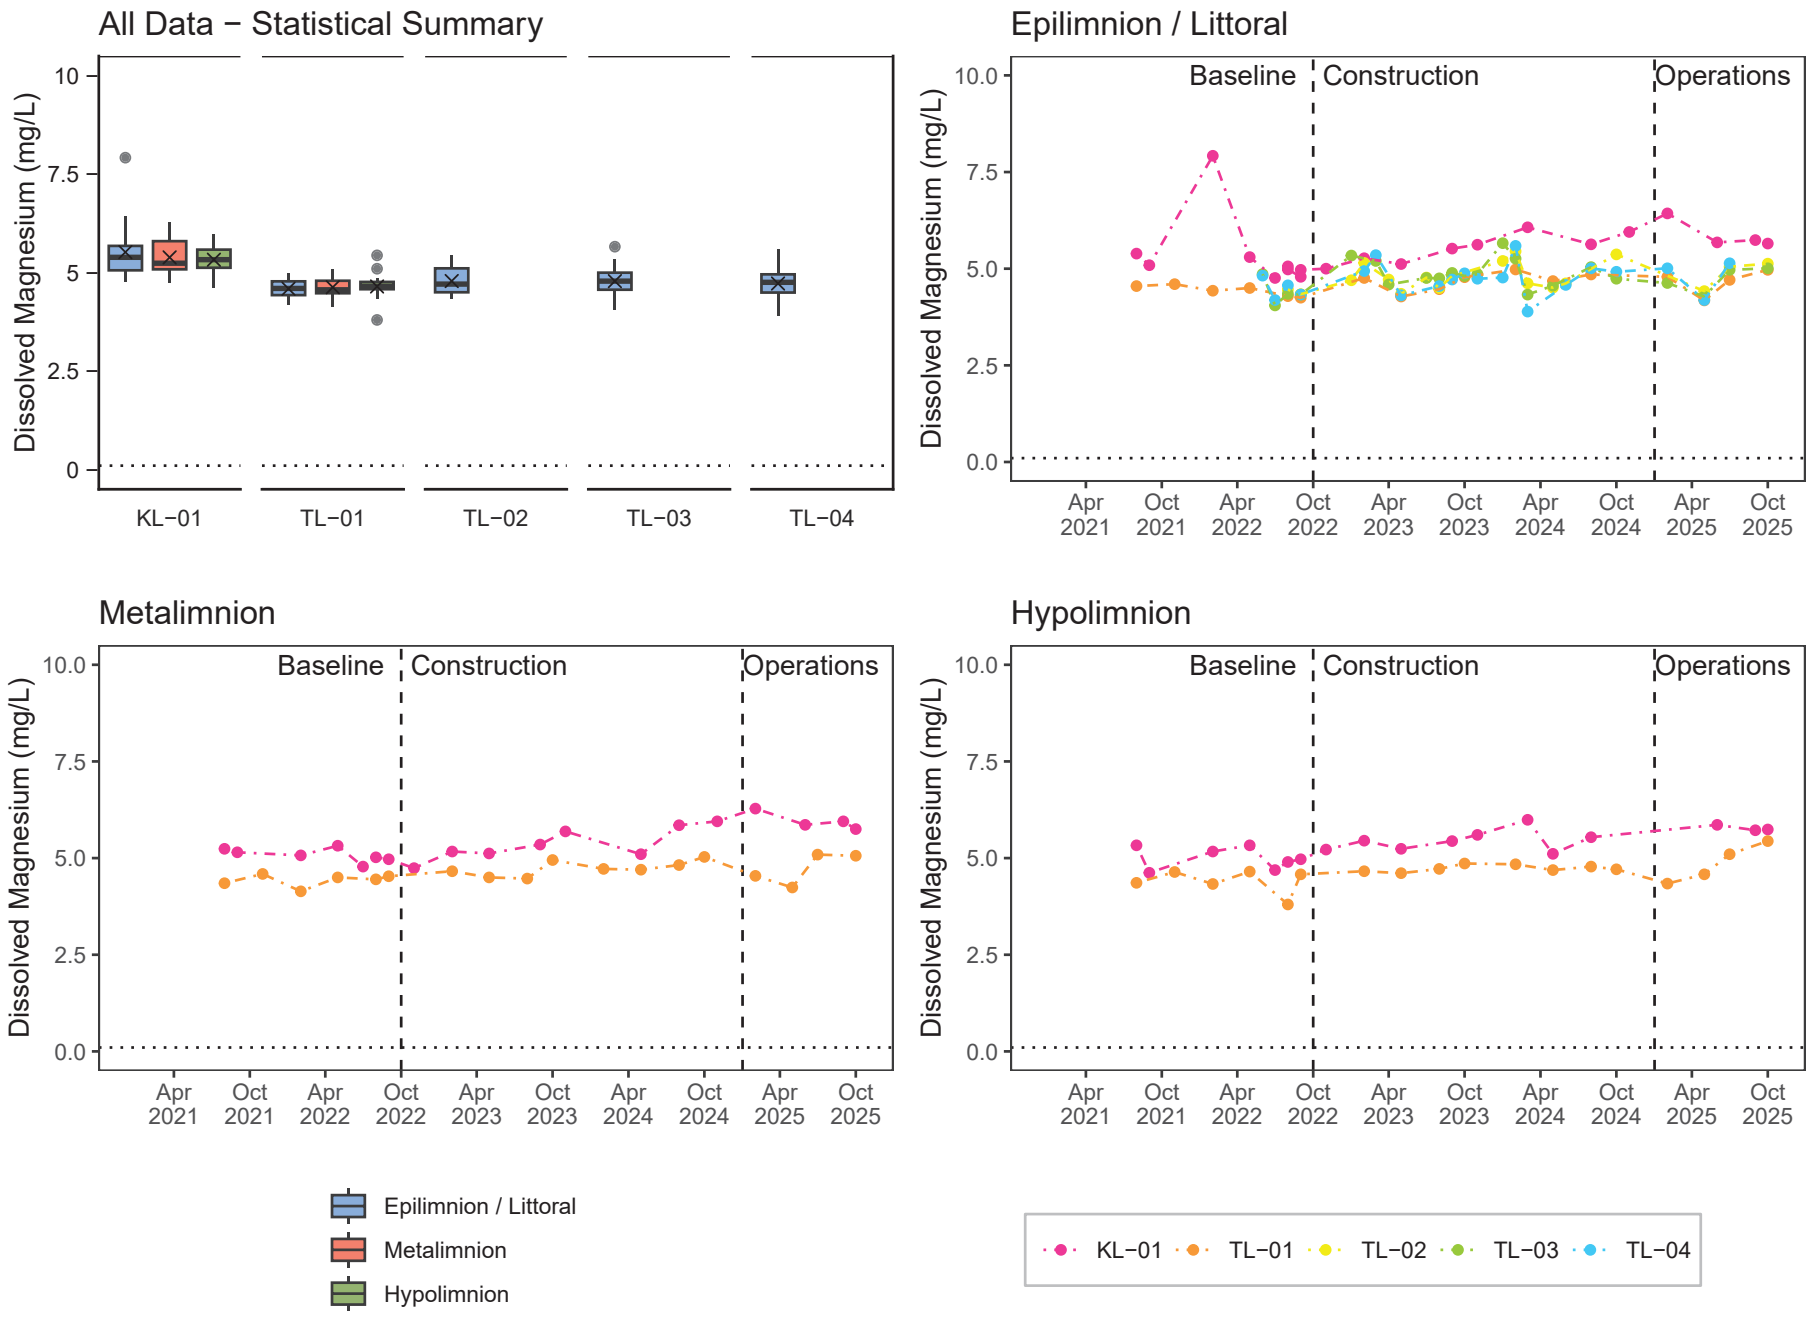
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.
Median BC WQG−AL long−term chronic guideline for dissolved lead for Project lakes is 0.0057 mg/L.

Figure A9−69: Dissolved Lead in AEMP Monitored Lakes, 2021 to 2025



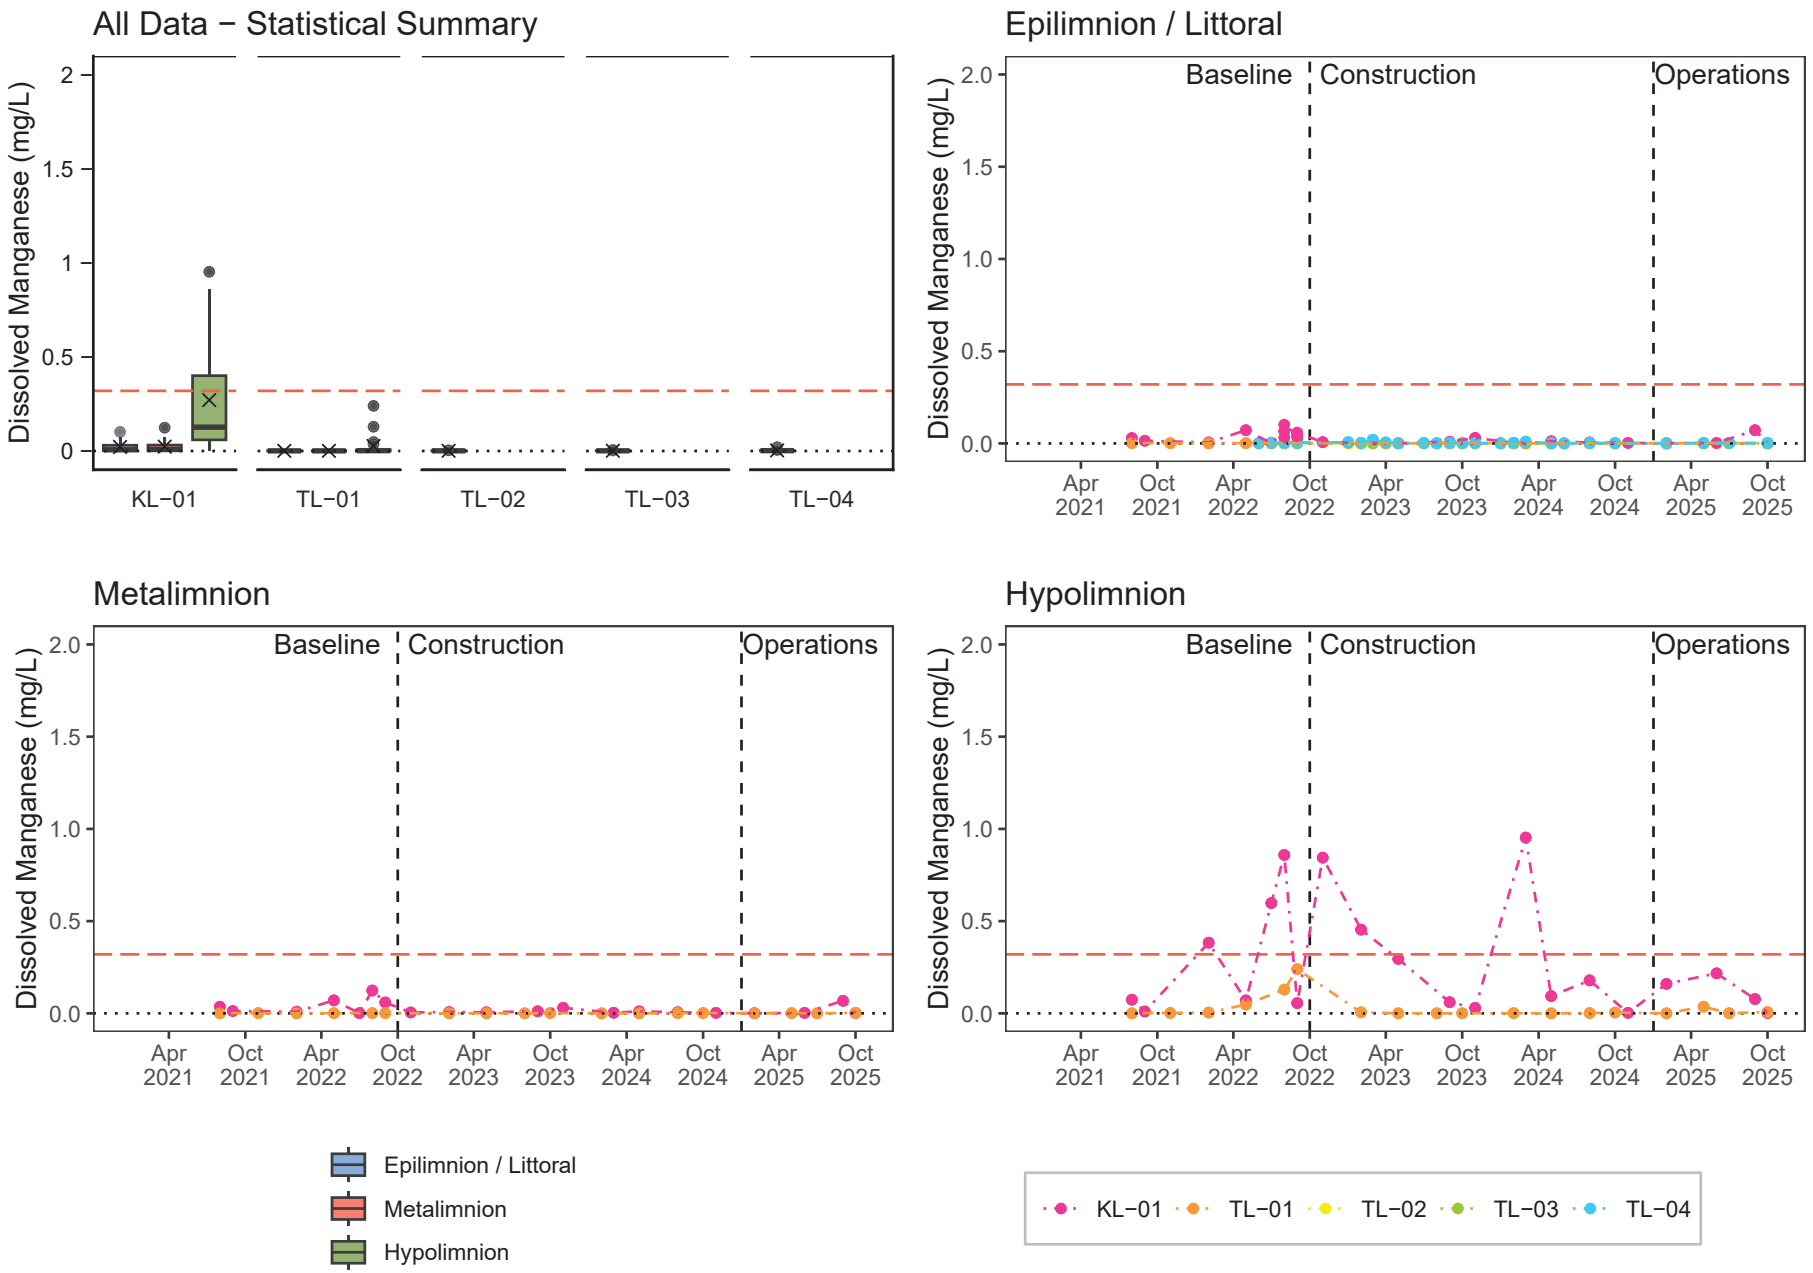
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−70: Dissolved Lithium in AEMP Monitored Lakes, 2021 to 2025



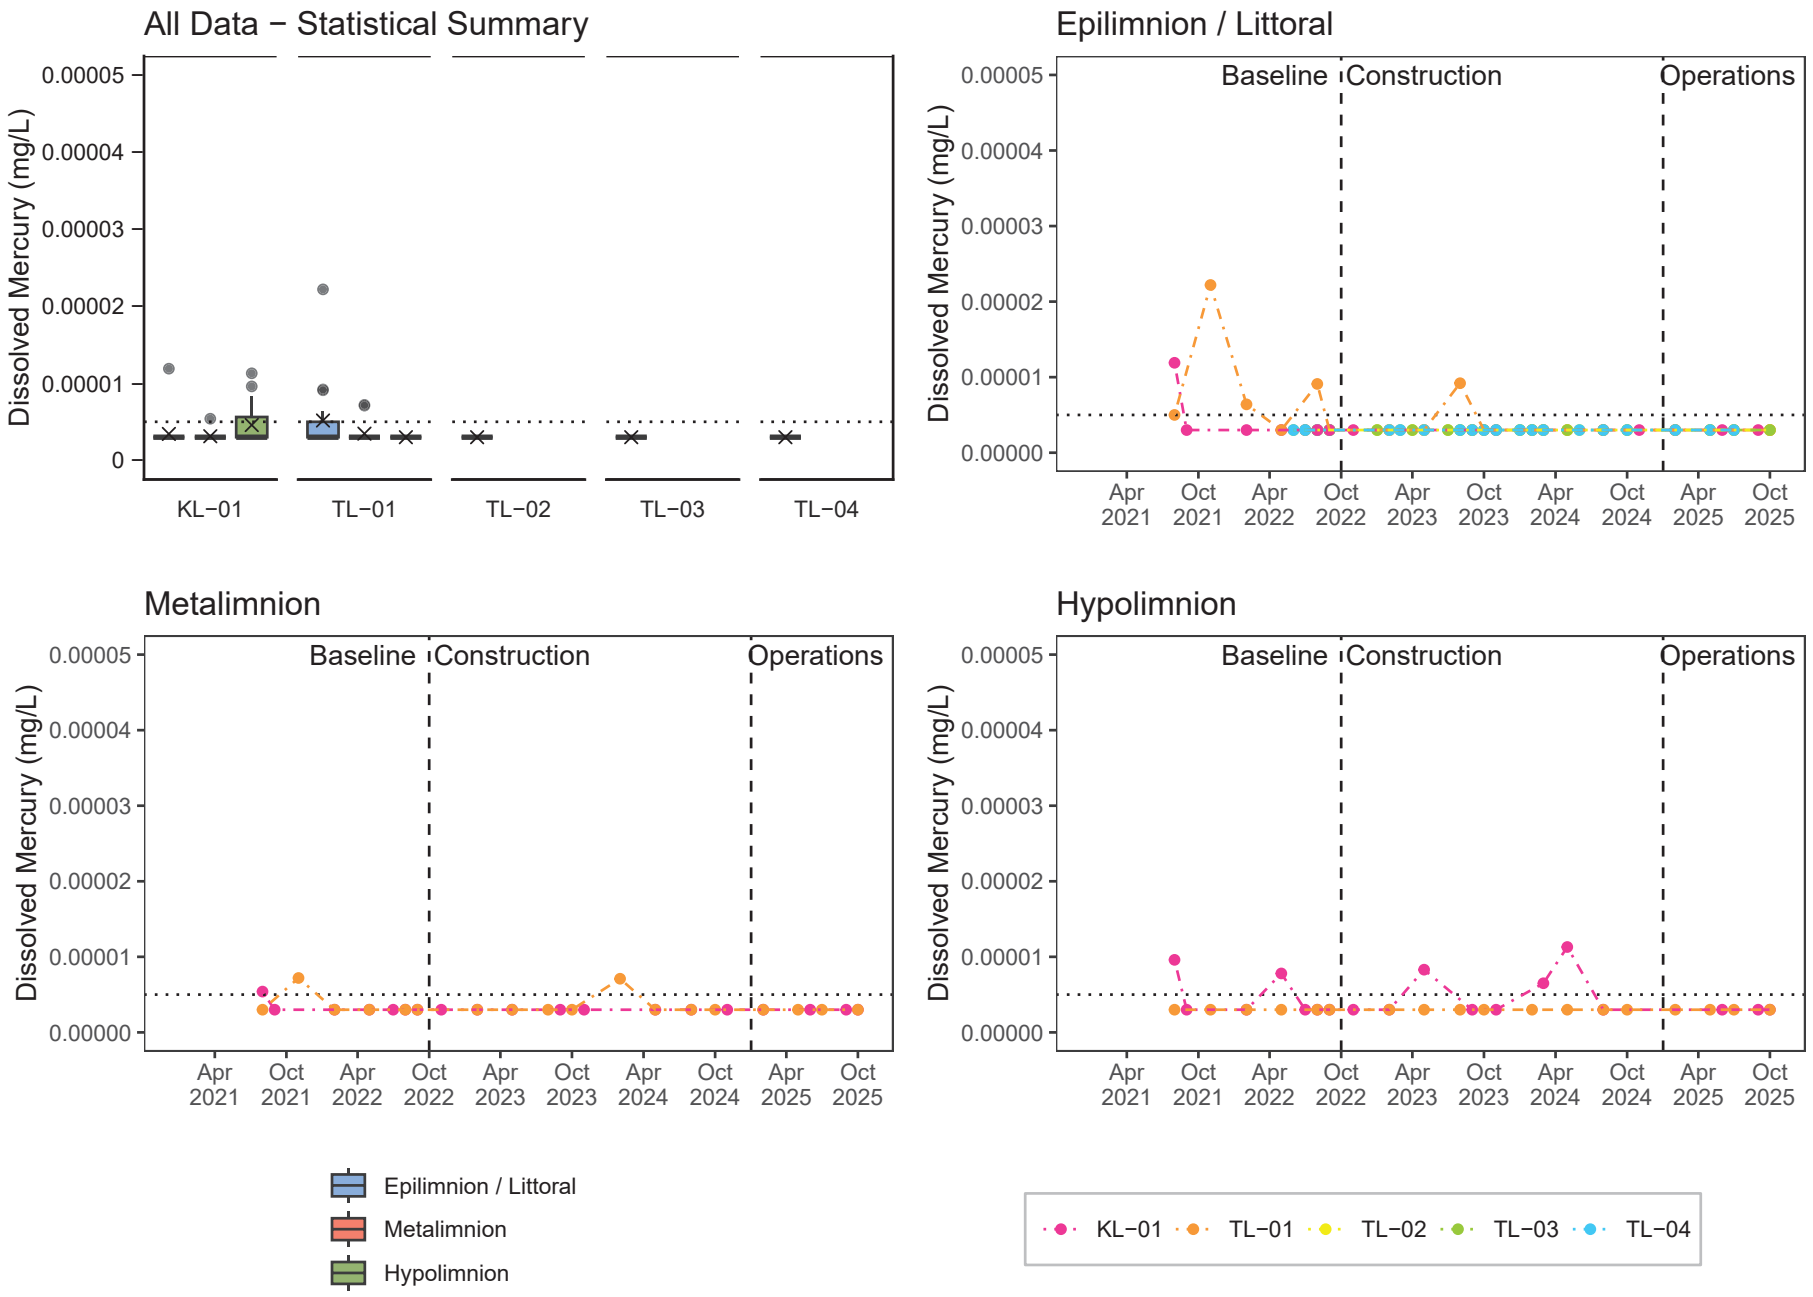
Notes: Dashed line indicates minimum detection limits.

Figure A9−71: Dissolved Magnesium in AEMP Monitored Lakes, 2021 to 2025



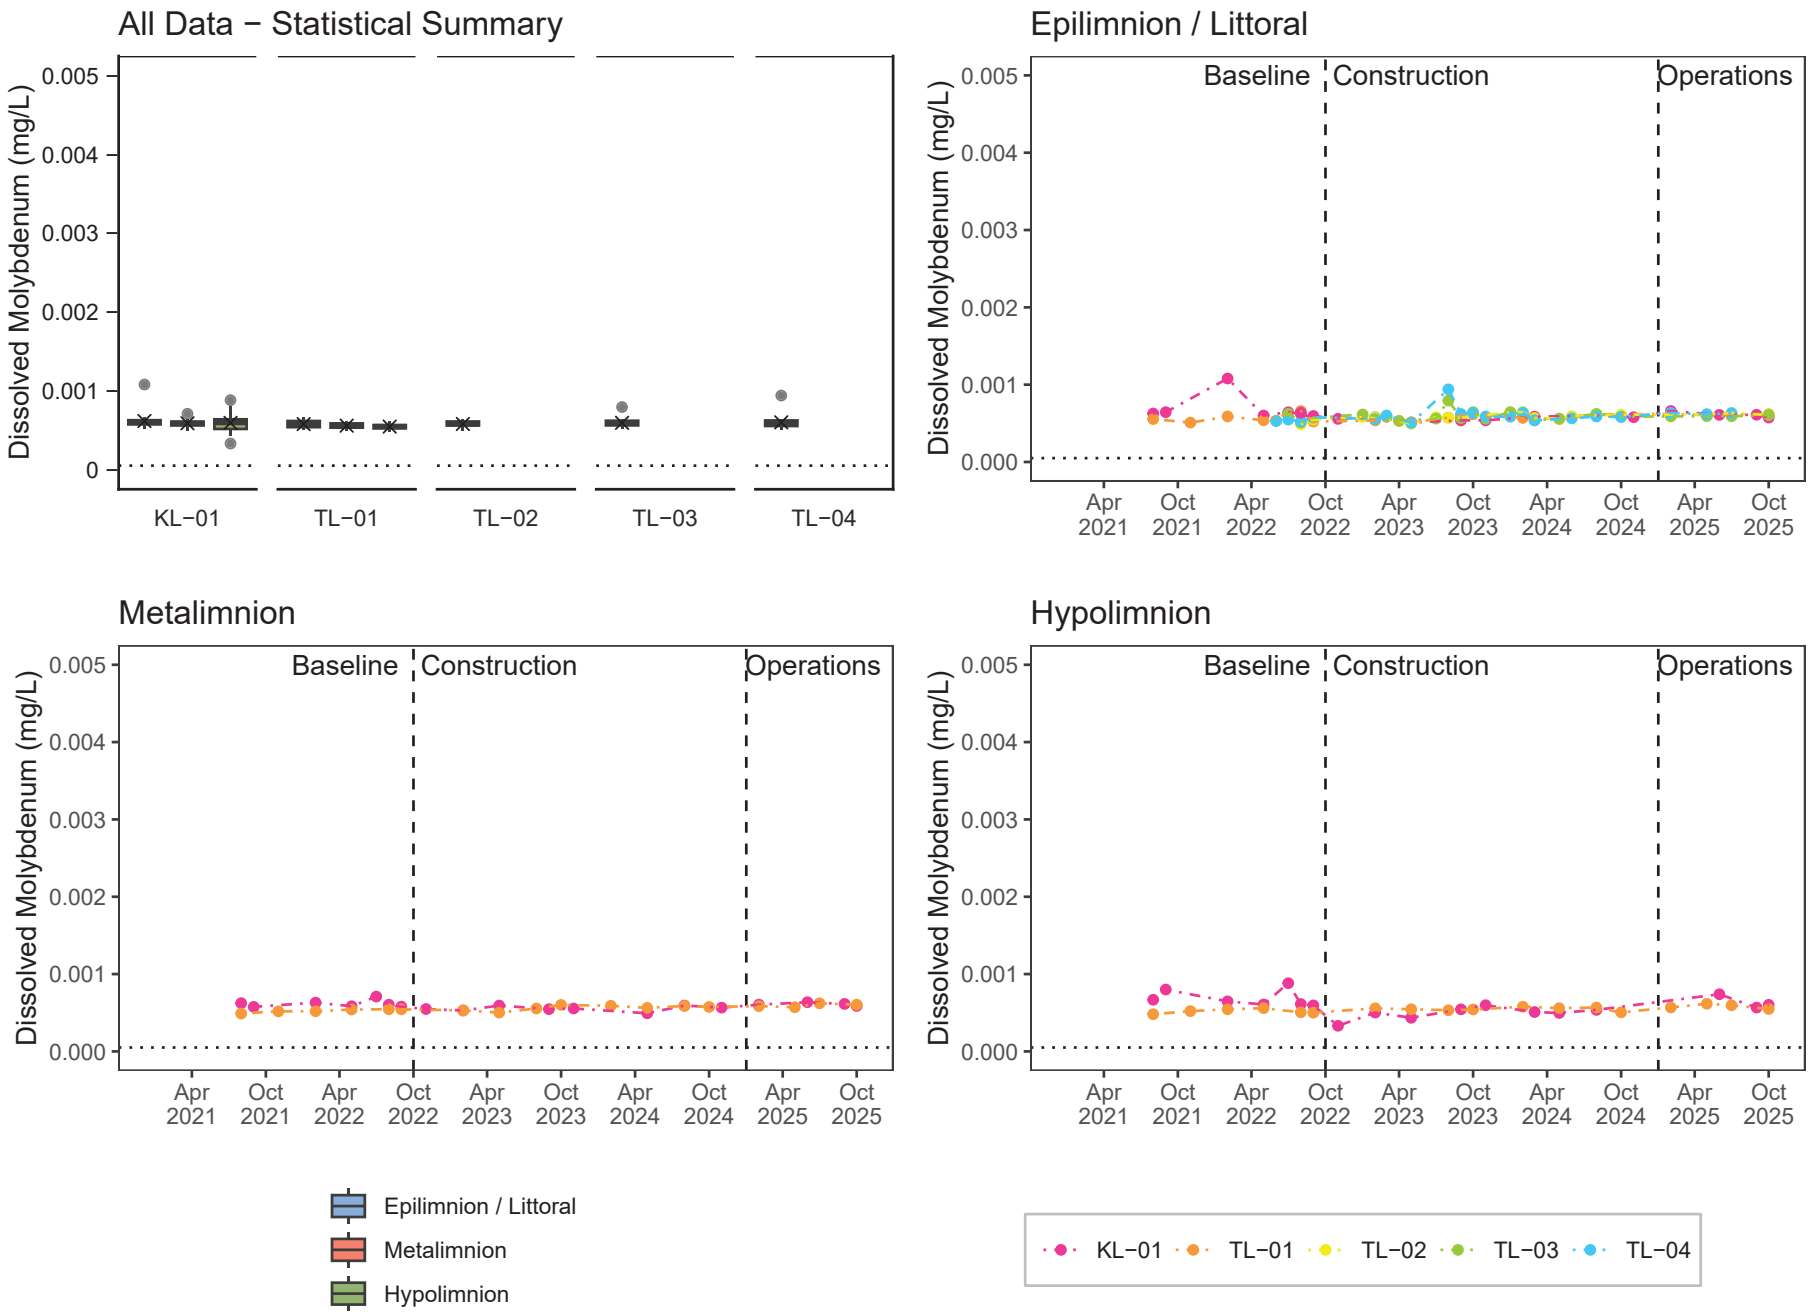
Notes: Dashed line indicates minimum detection limits.
Median CCME WQG−AL long−term chronic guideline for dissolved manganese for Project lakes is 0.32 mg/L.
Median CCME WQG−AL short−term acute guideline for dissolved manganese for Project lakes is 4.9 mg/L.

Figure A9−72: Dissolved Manganese in AEMP Monitored Lakes, 2021 to 2025



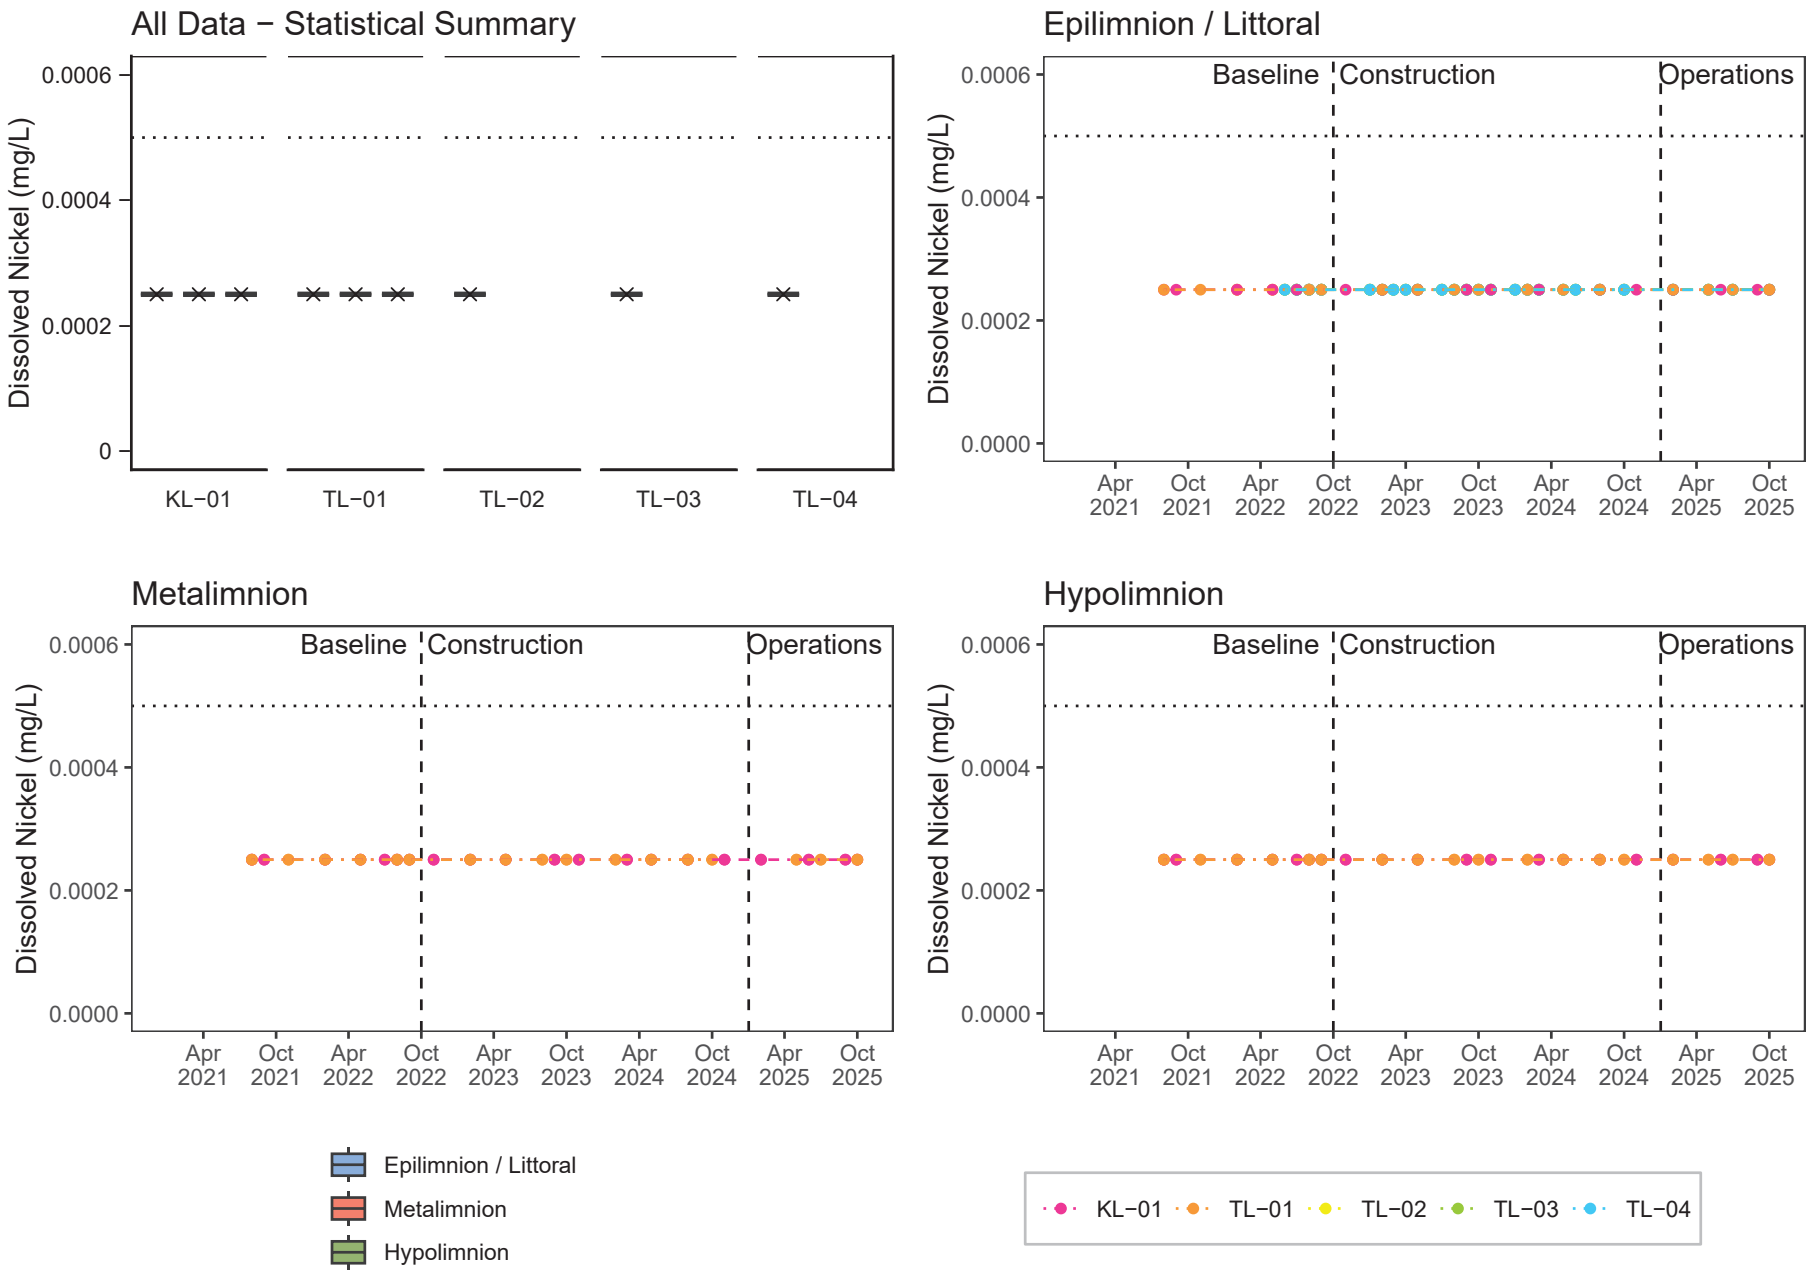
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−73: Dissolved Mercury in AEMP Monitored Lakes, 2021 to 2025



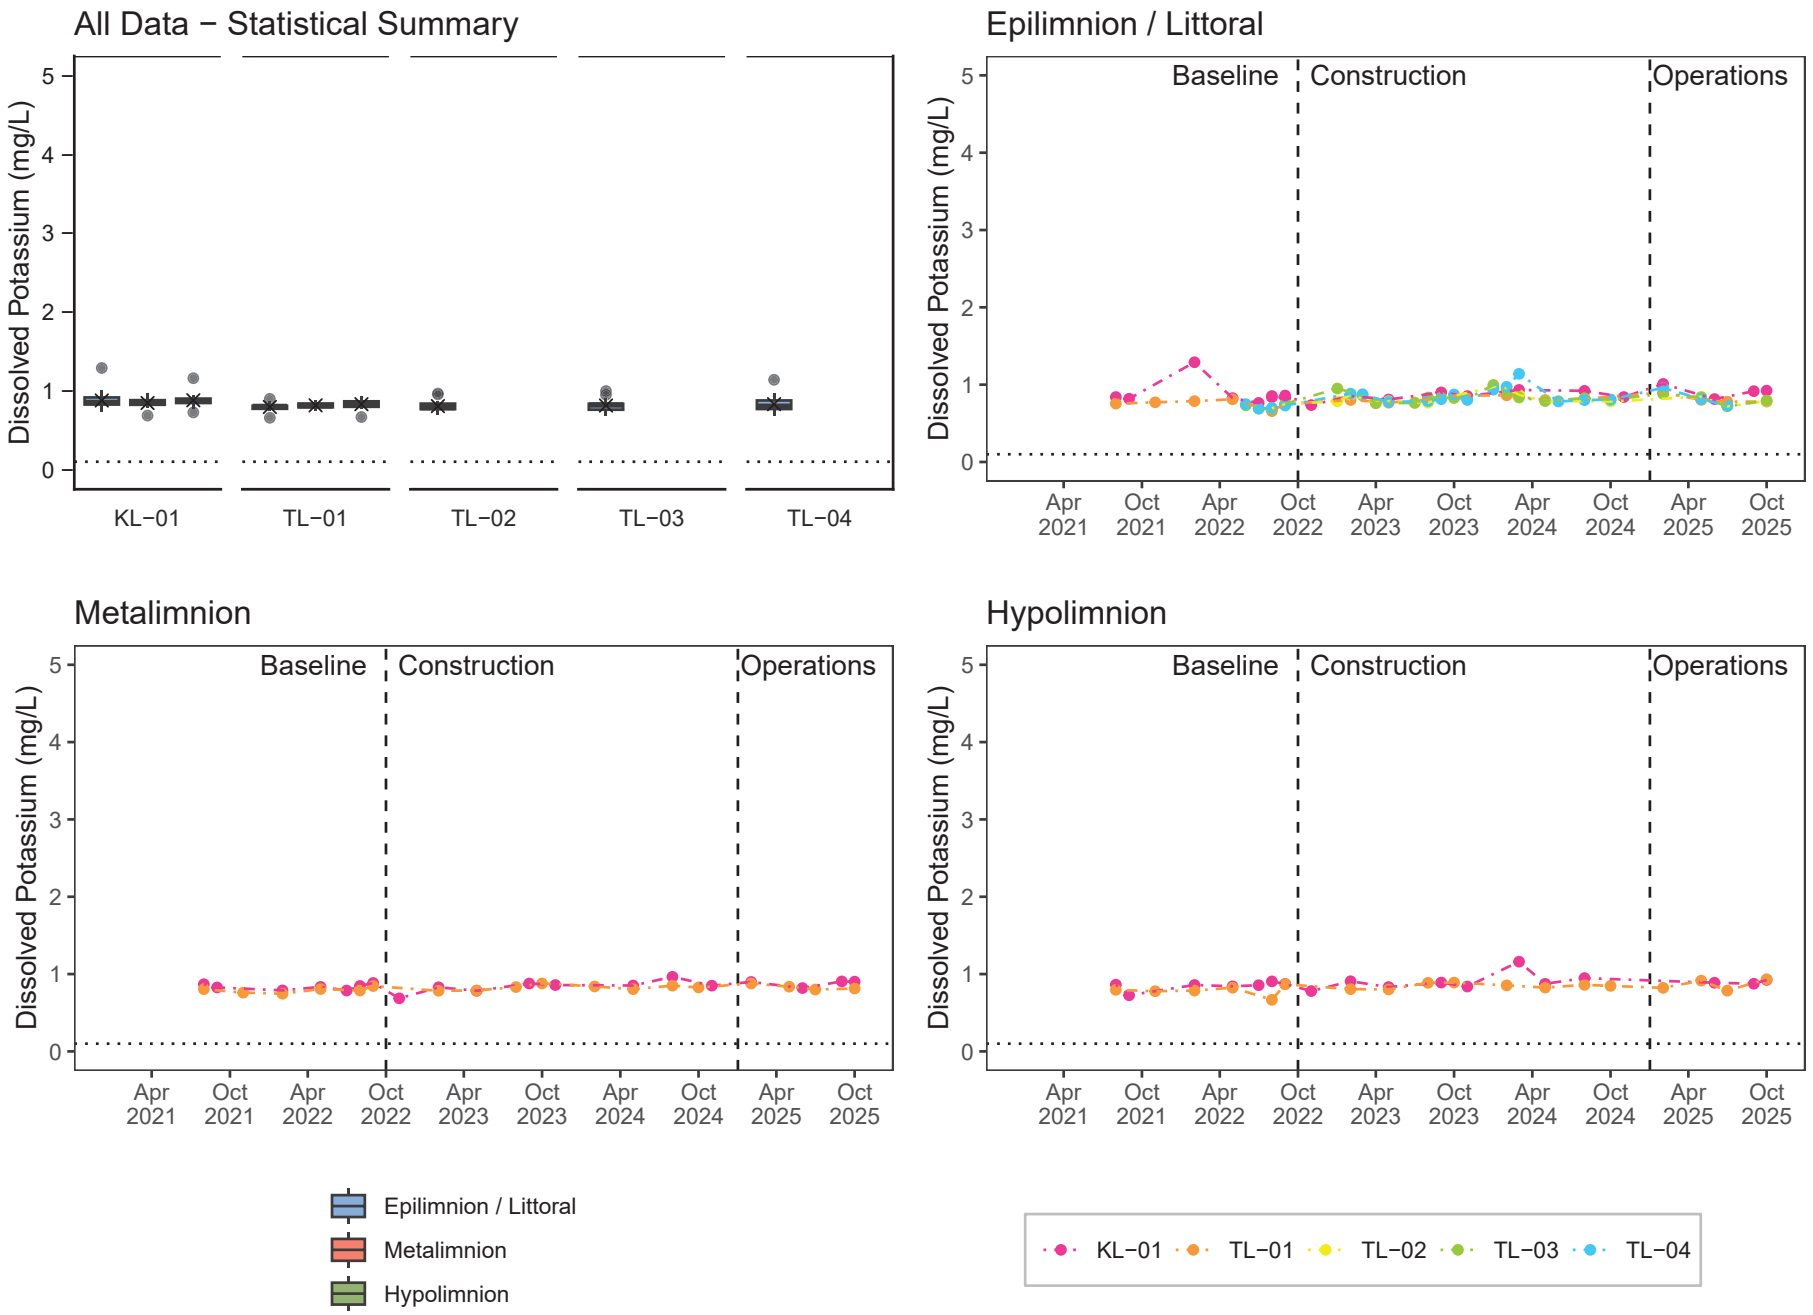
Notes: Dashed line indicates minimum detection limits.

Figure A9−74: Dissolved Molybdenum in AEMP Monitored Lakes, 2021 to 2025



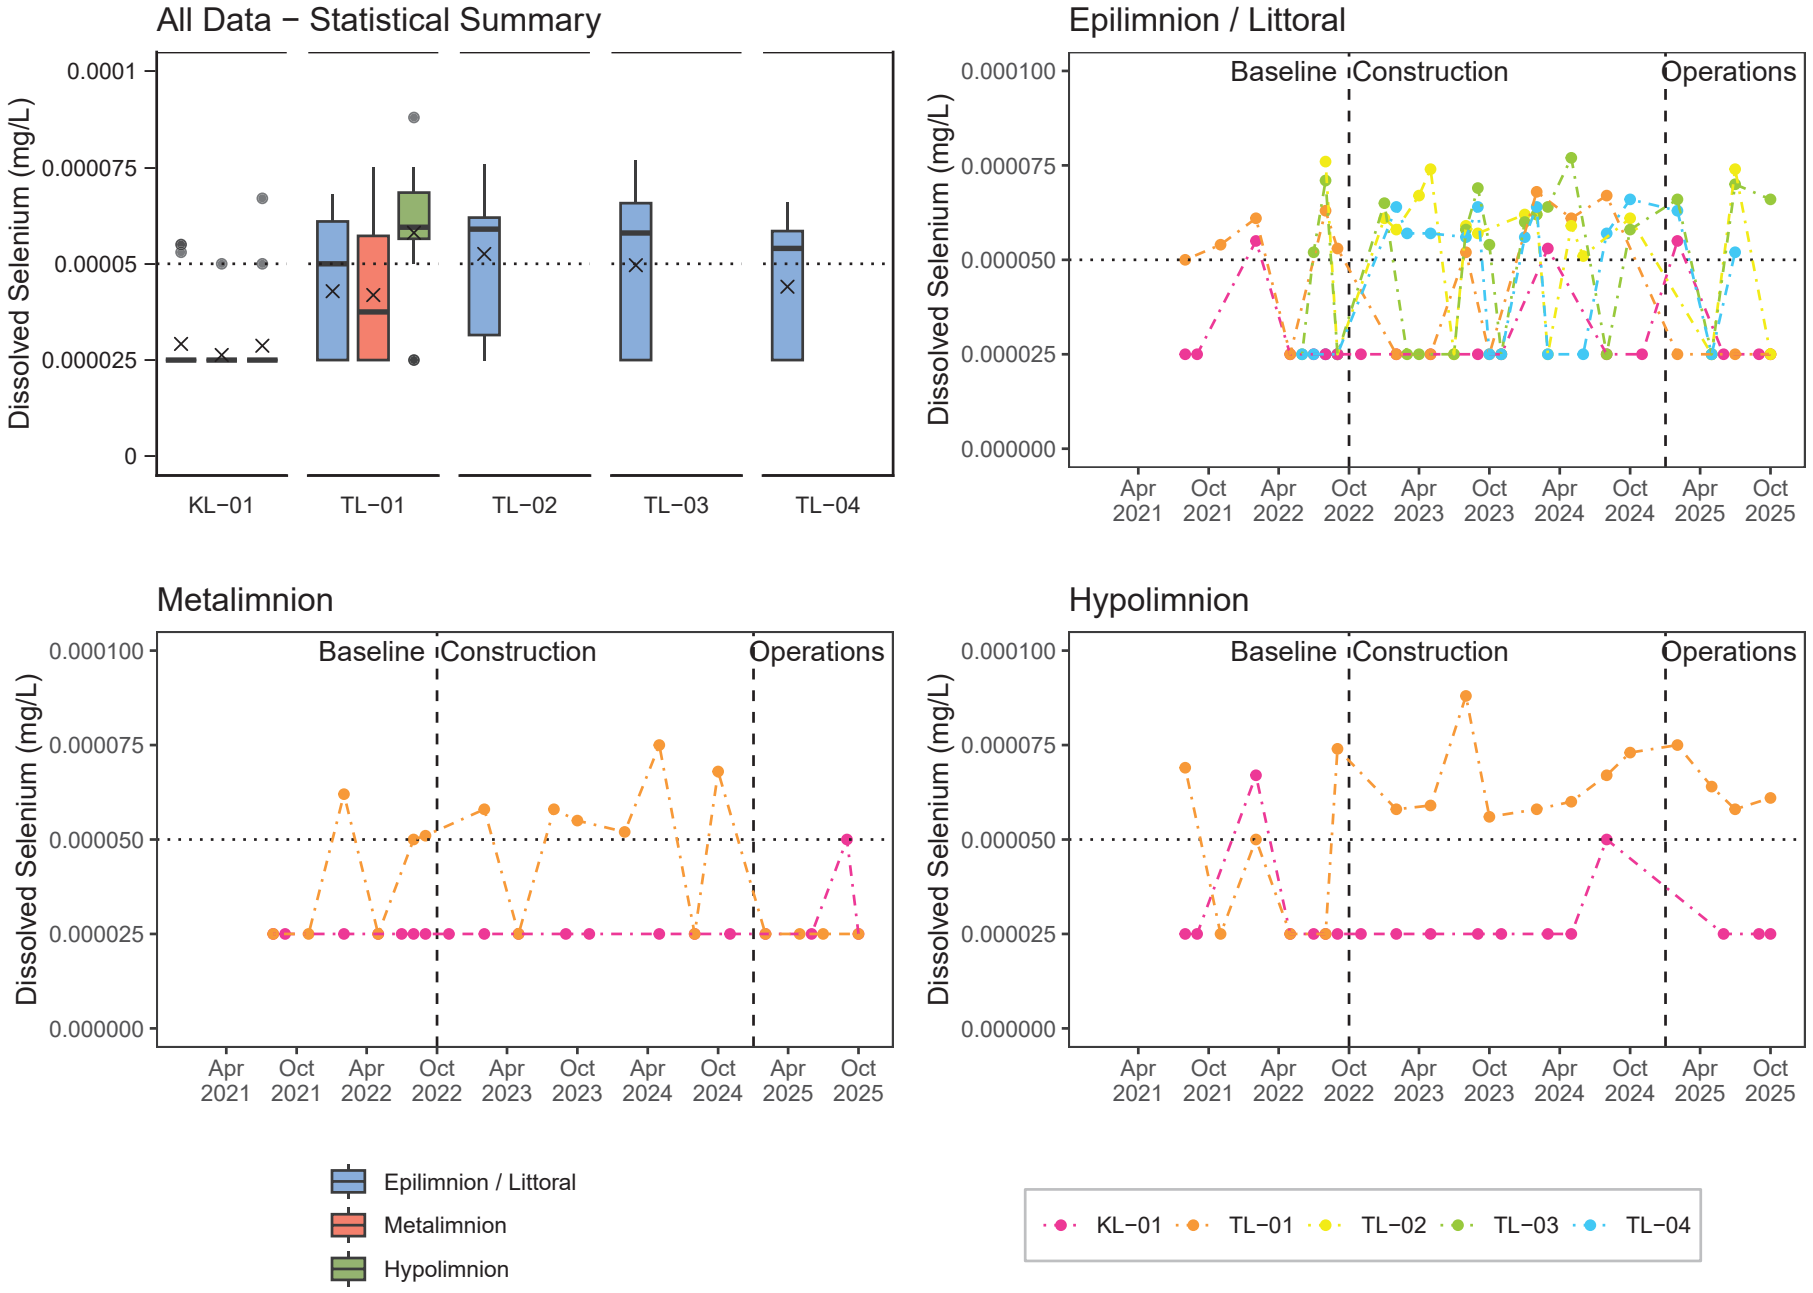
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.
Median BC BLM guideline for dissolved nickel for Project lakes is 0.0068 mg/L.

Figure A9−75: Dissolved Nickel in AEMP Monitored Lakes, 2021 to 2025



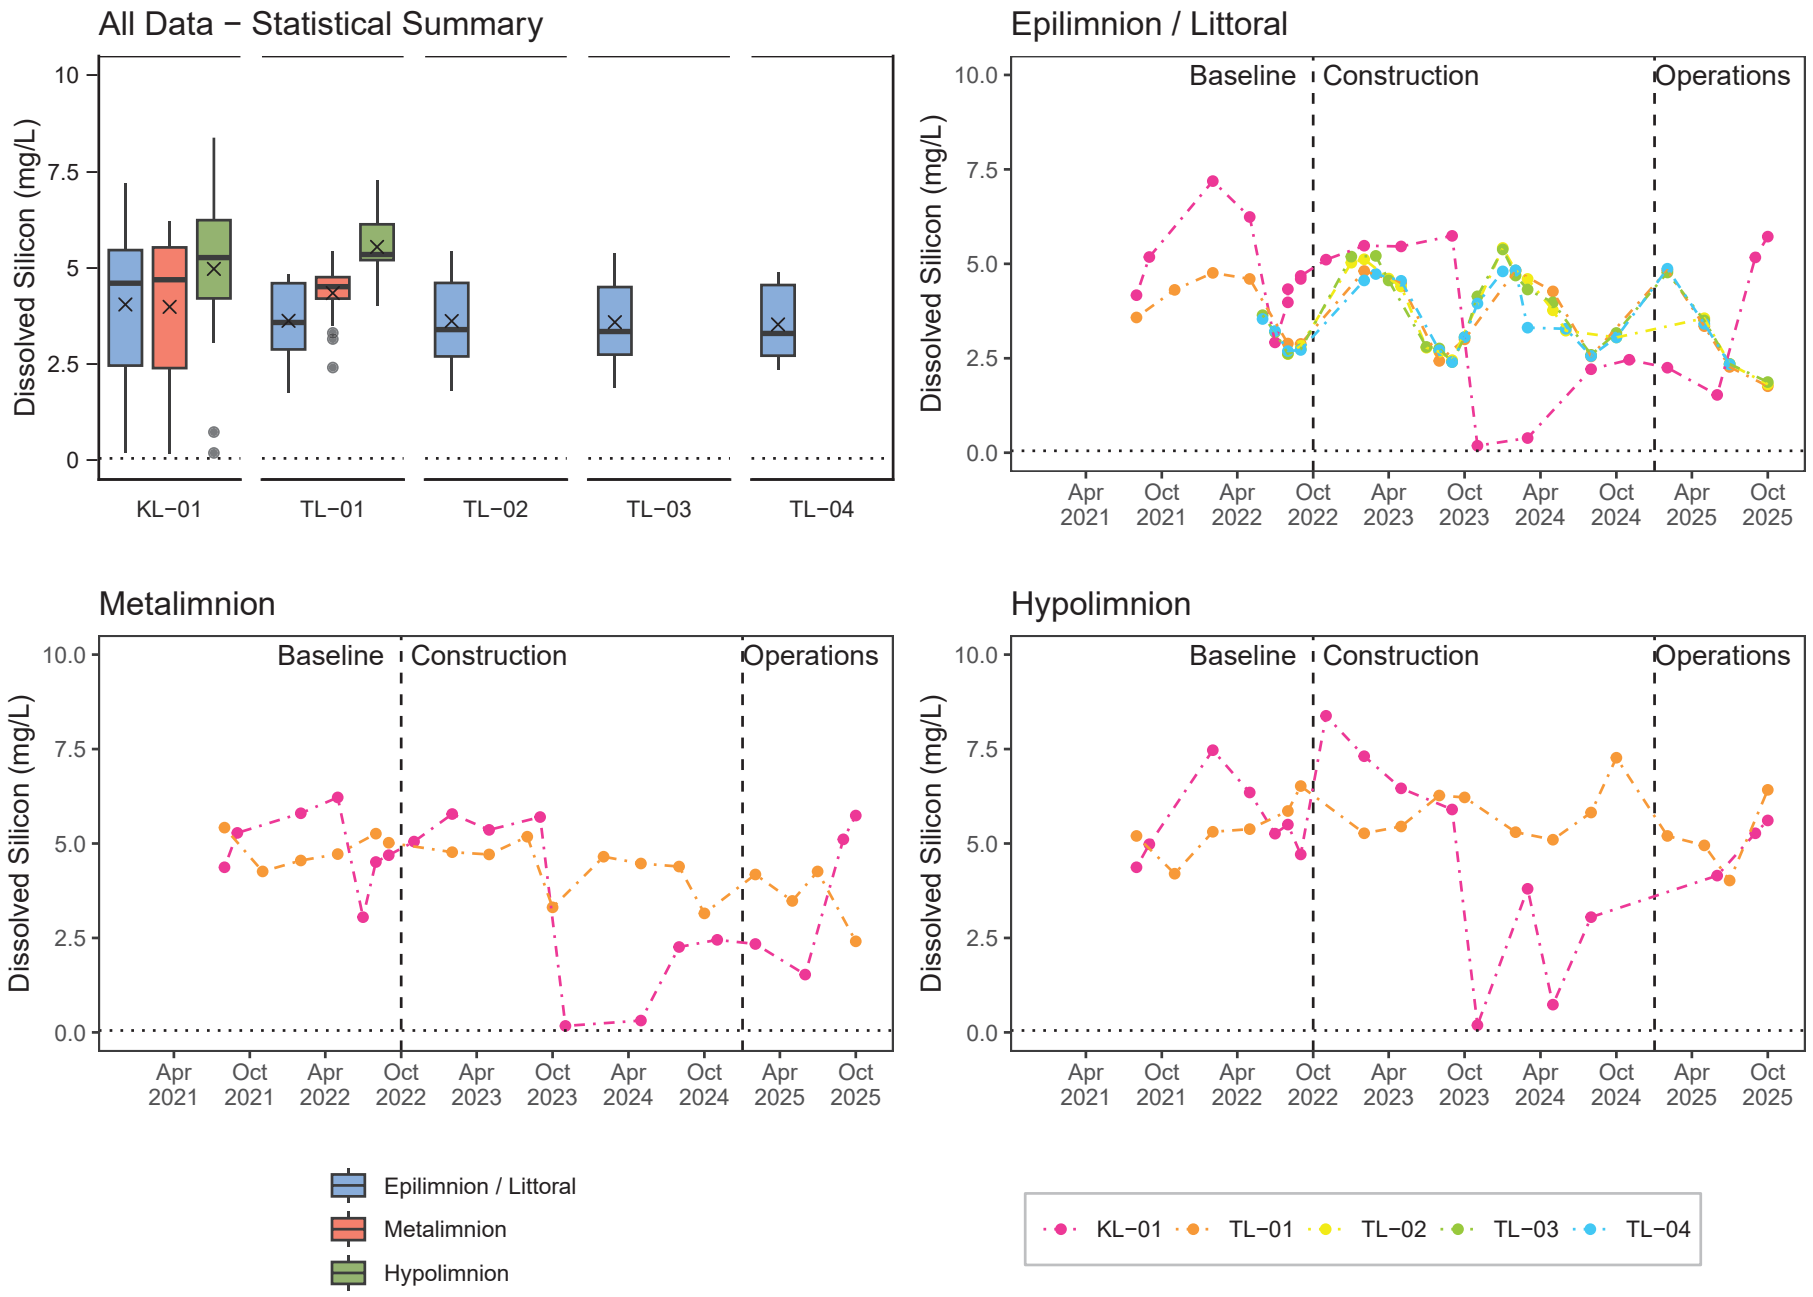
Notes: Dashed line indicates minimum detection limits.

Figure A9−76: Dissolved Potassium in AEMP Monitored Lakes, 2021 to 2025



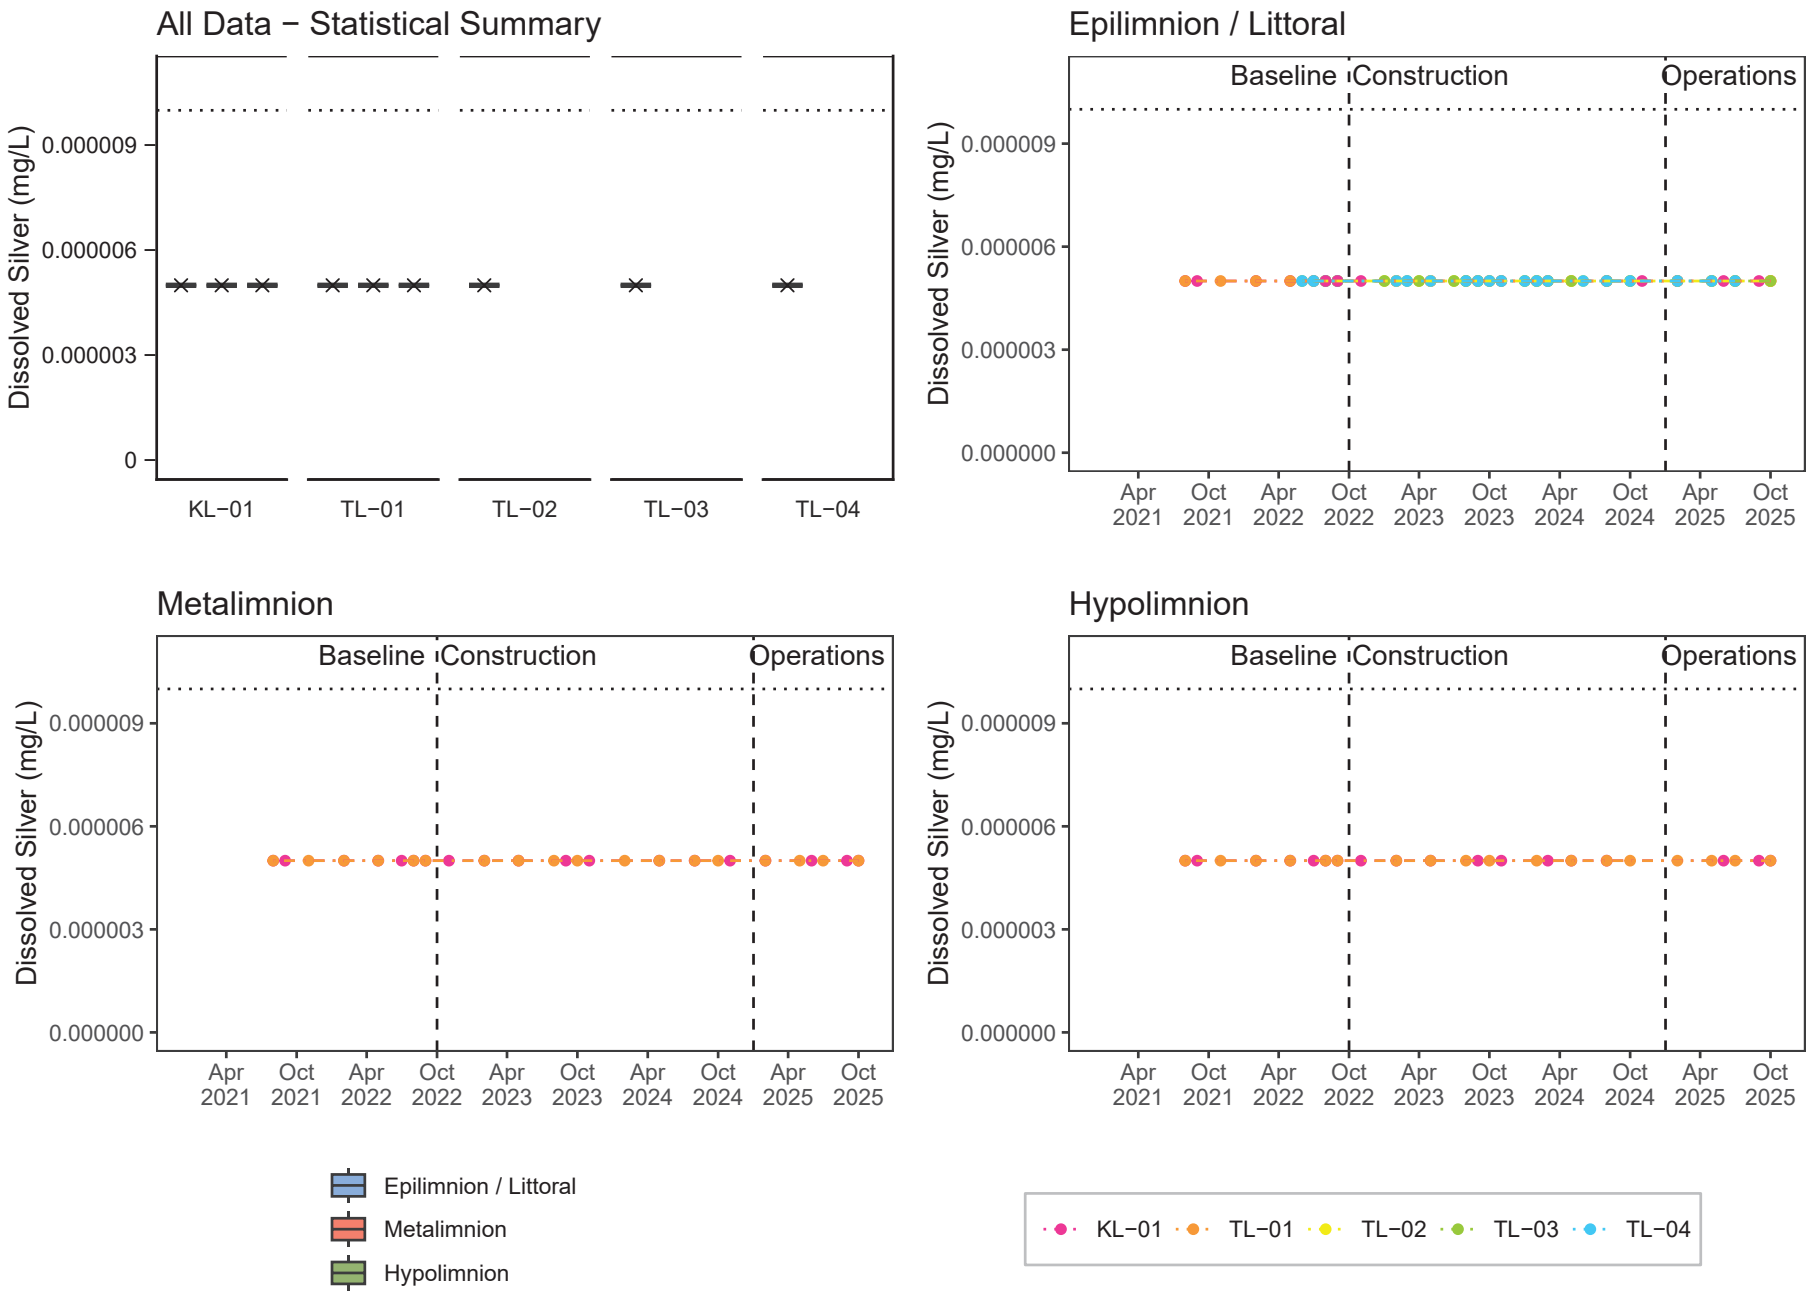
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−77: Dissolved Selenium in AEMP Monitored Lakes, 2021 to 2025



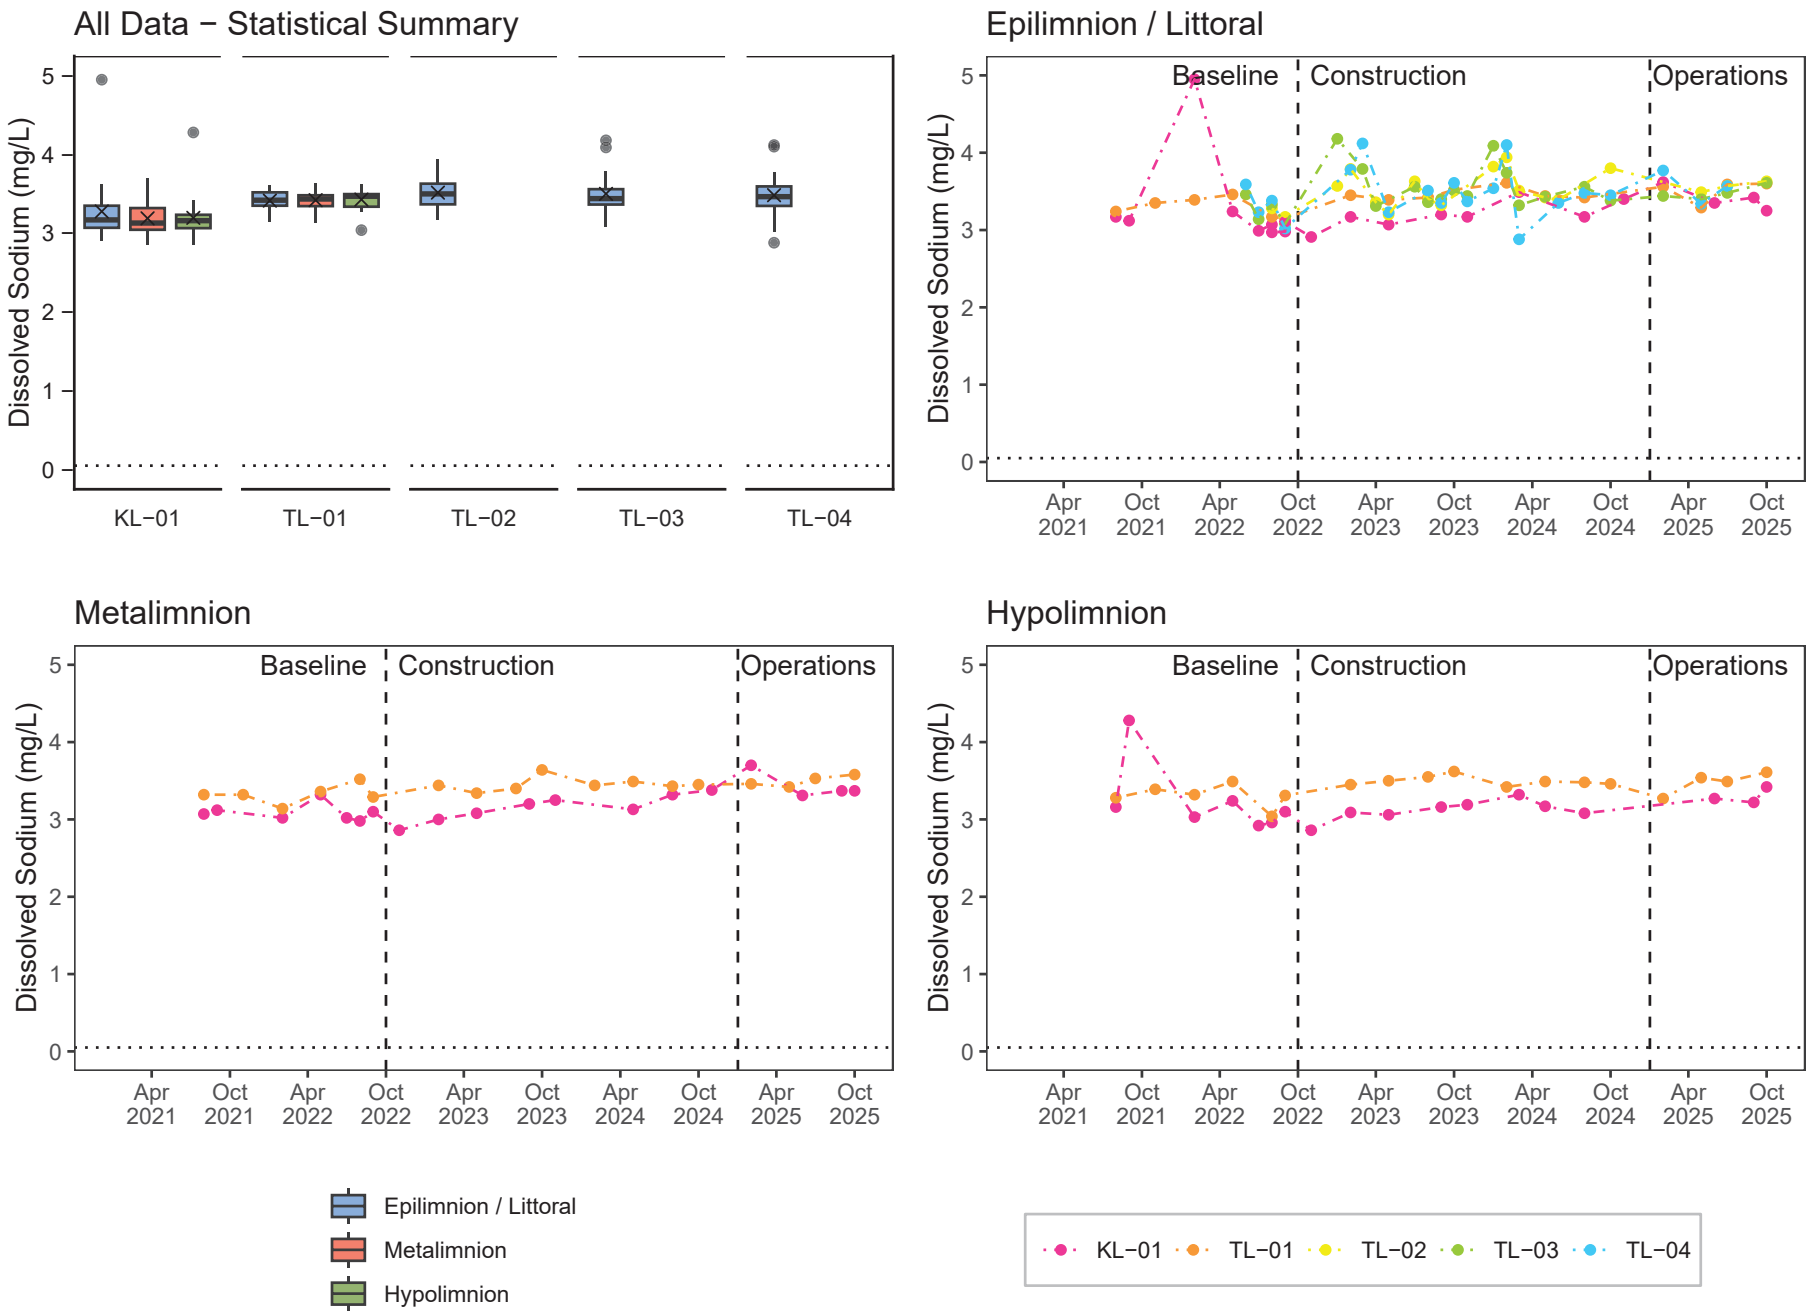
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−78: Dissolved Silicon in AEMP Monitored Lakes, 2021 to 2025



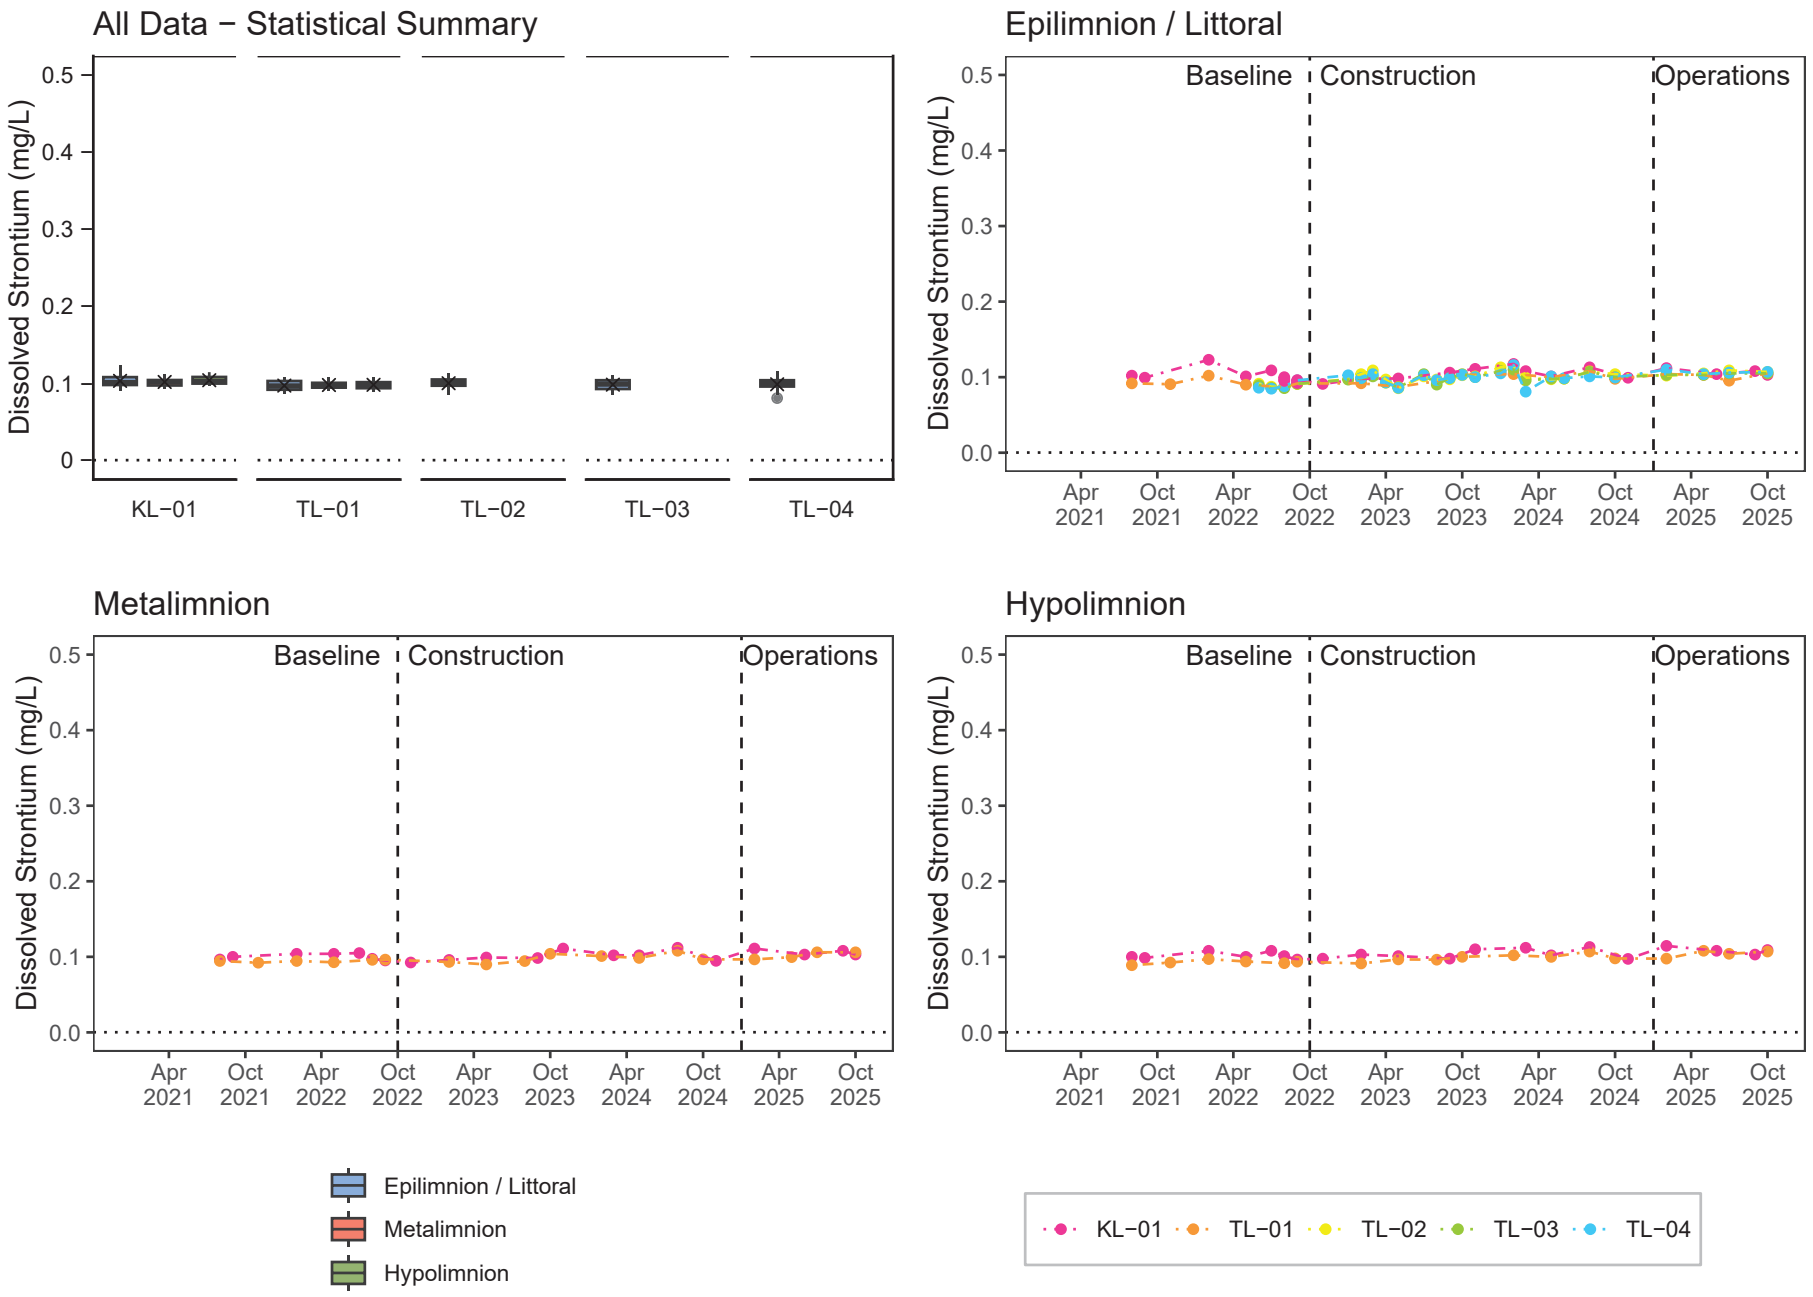
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−79: Dissolved Silver in AEMP Monitored Lakes, 2021 to 2025



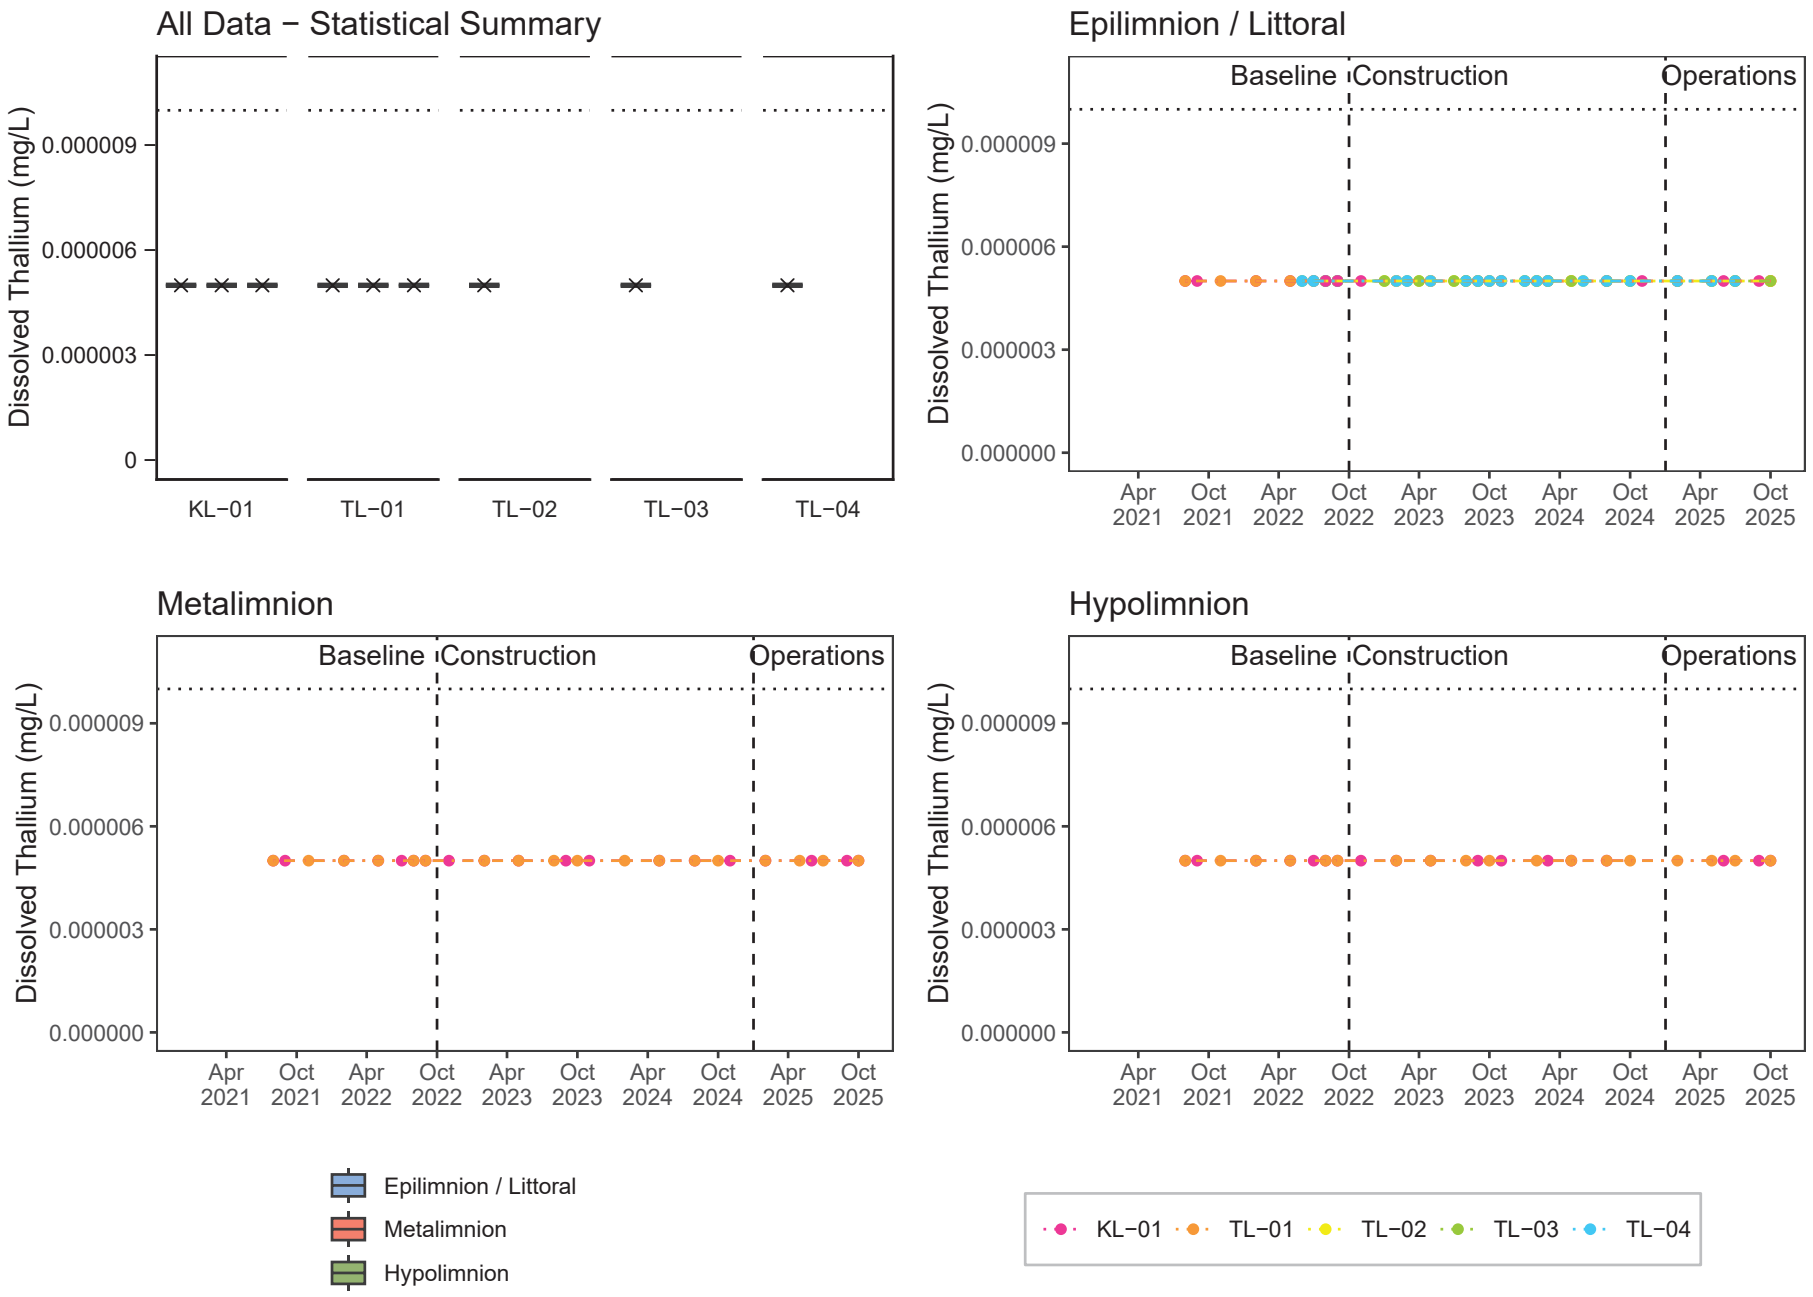
Notes: Dashed line indicates minimum detection limits.

Figure A9−80: Dissolved Sodium in AEMP Monitored Lakes, 2021 to 2025



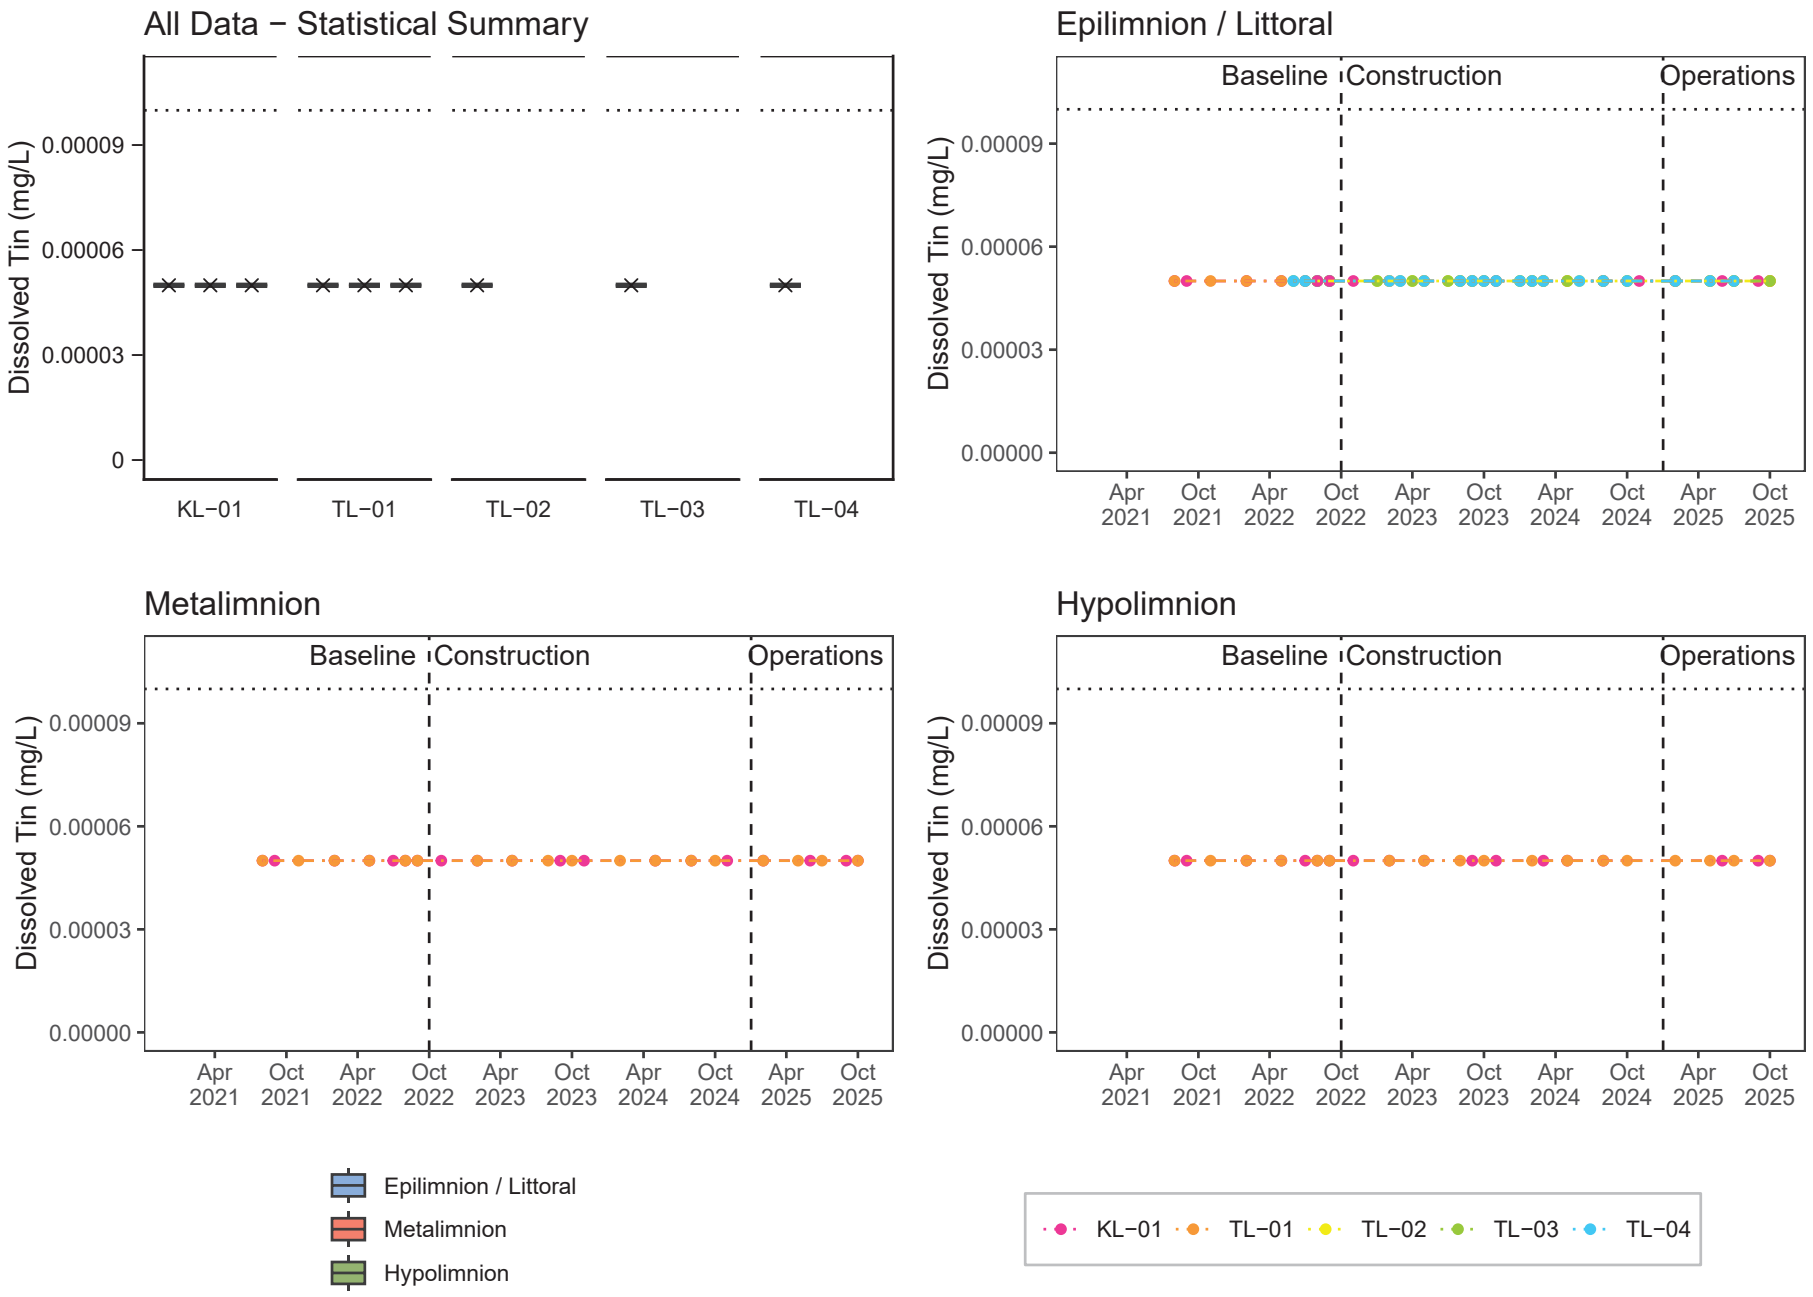
Notes: Dashed line indicates minimum detection limits.
BC WQG−AL working long−term guideline for dissolved strontium is 1.25 mg/L.

Figure A9−81: Dissolved Strontium in AEMP Monitored Lakes, 2021 to 2025



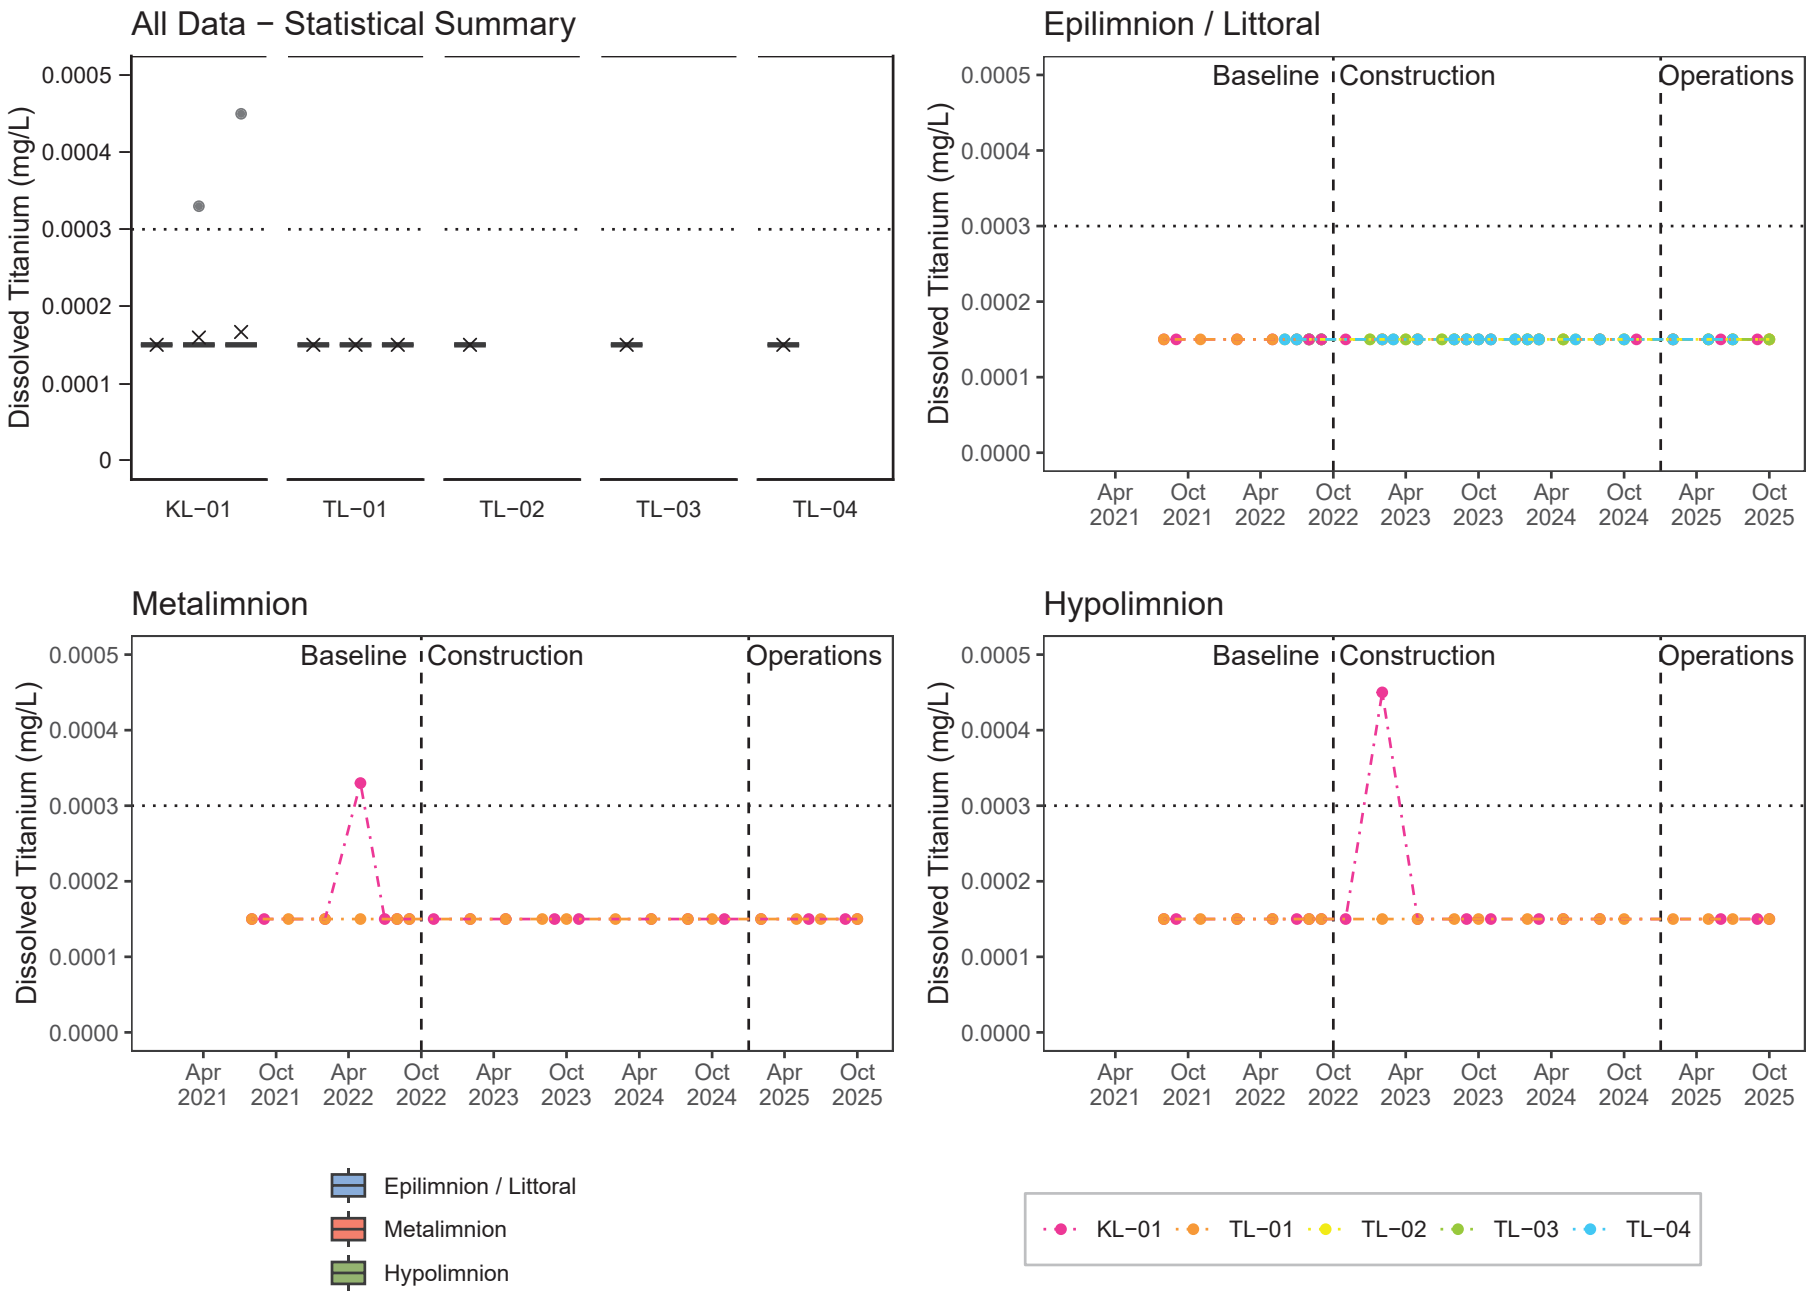
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−82: Dissolved Thallium in AEMP Monitored Lakes, 2021 to 2025



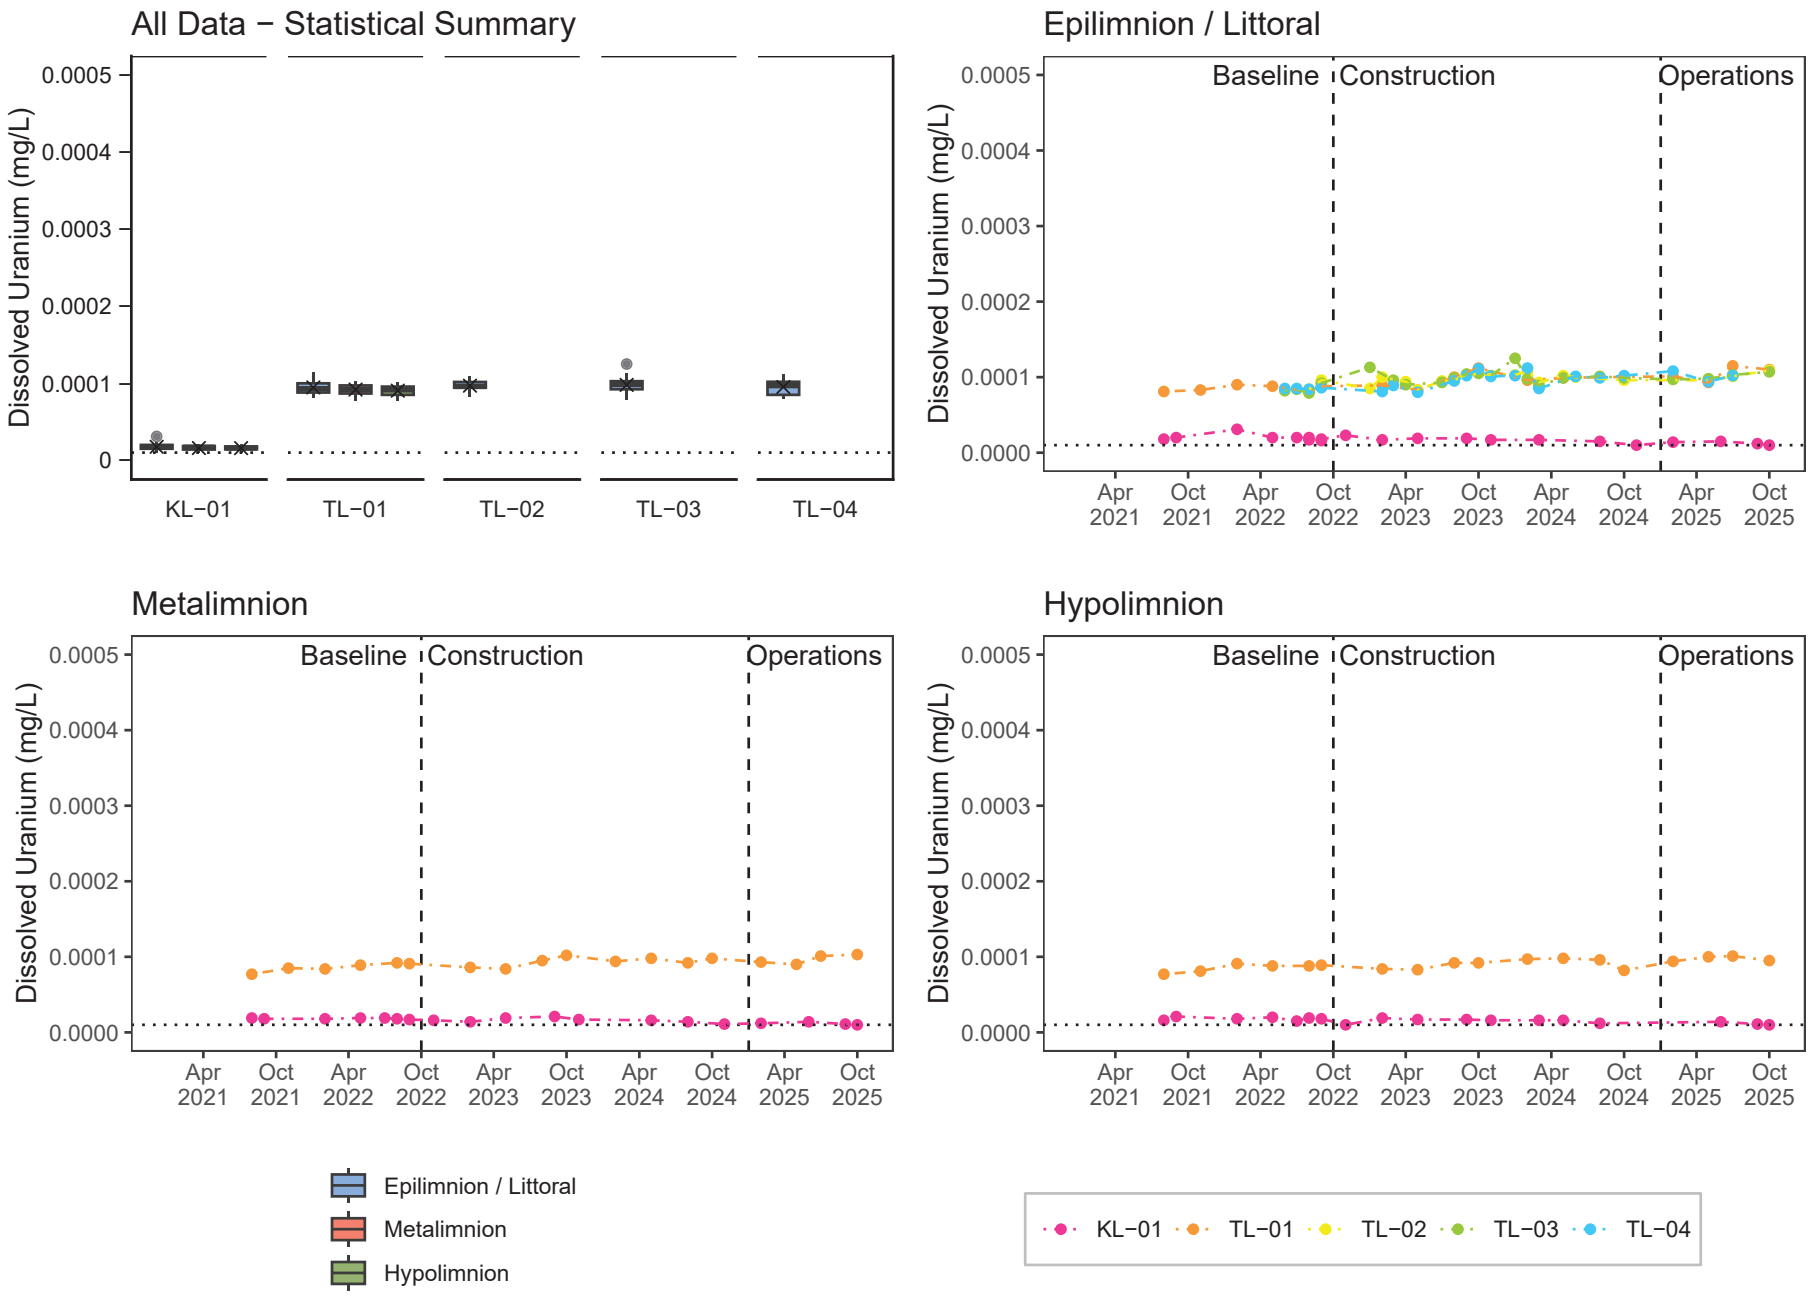
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−83: Dissolved Tin in AEMP Monitored Lakes, 2021 to 2025



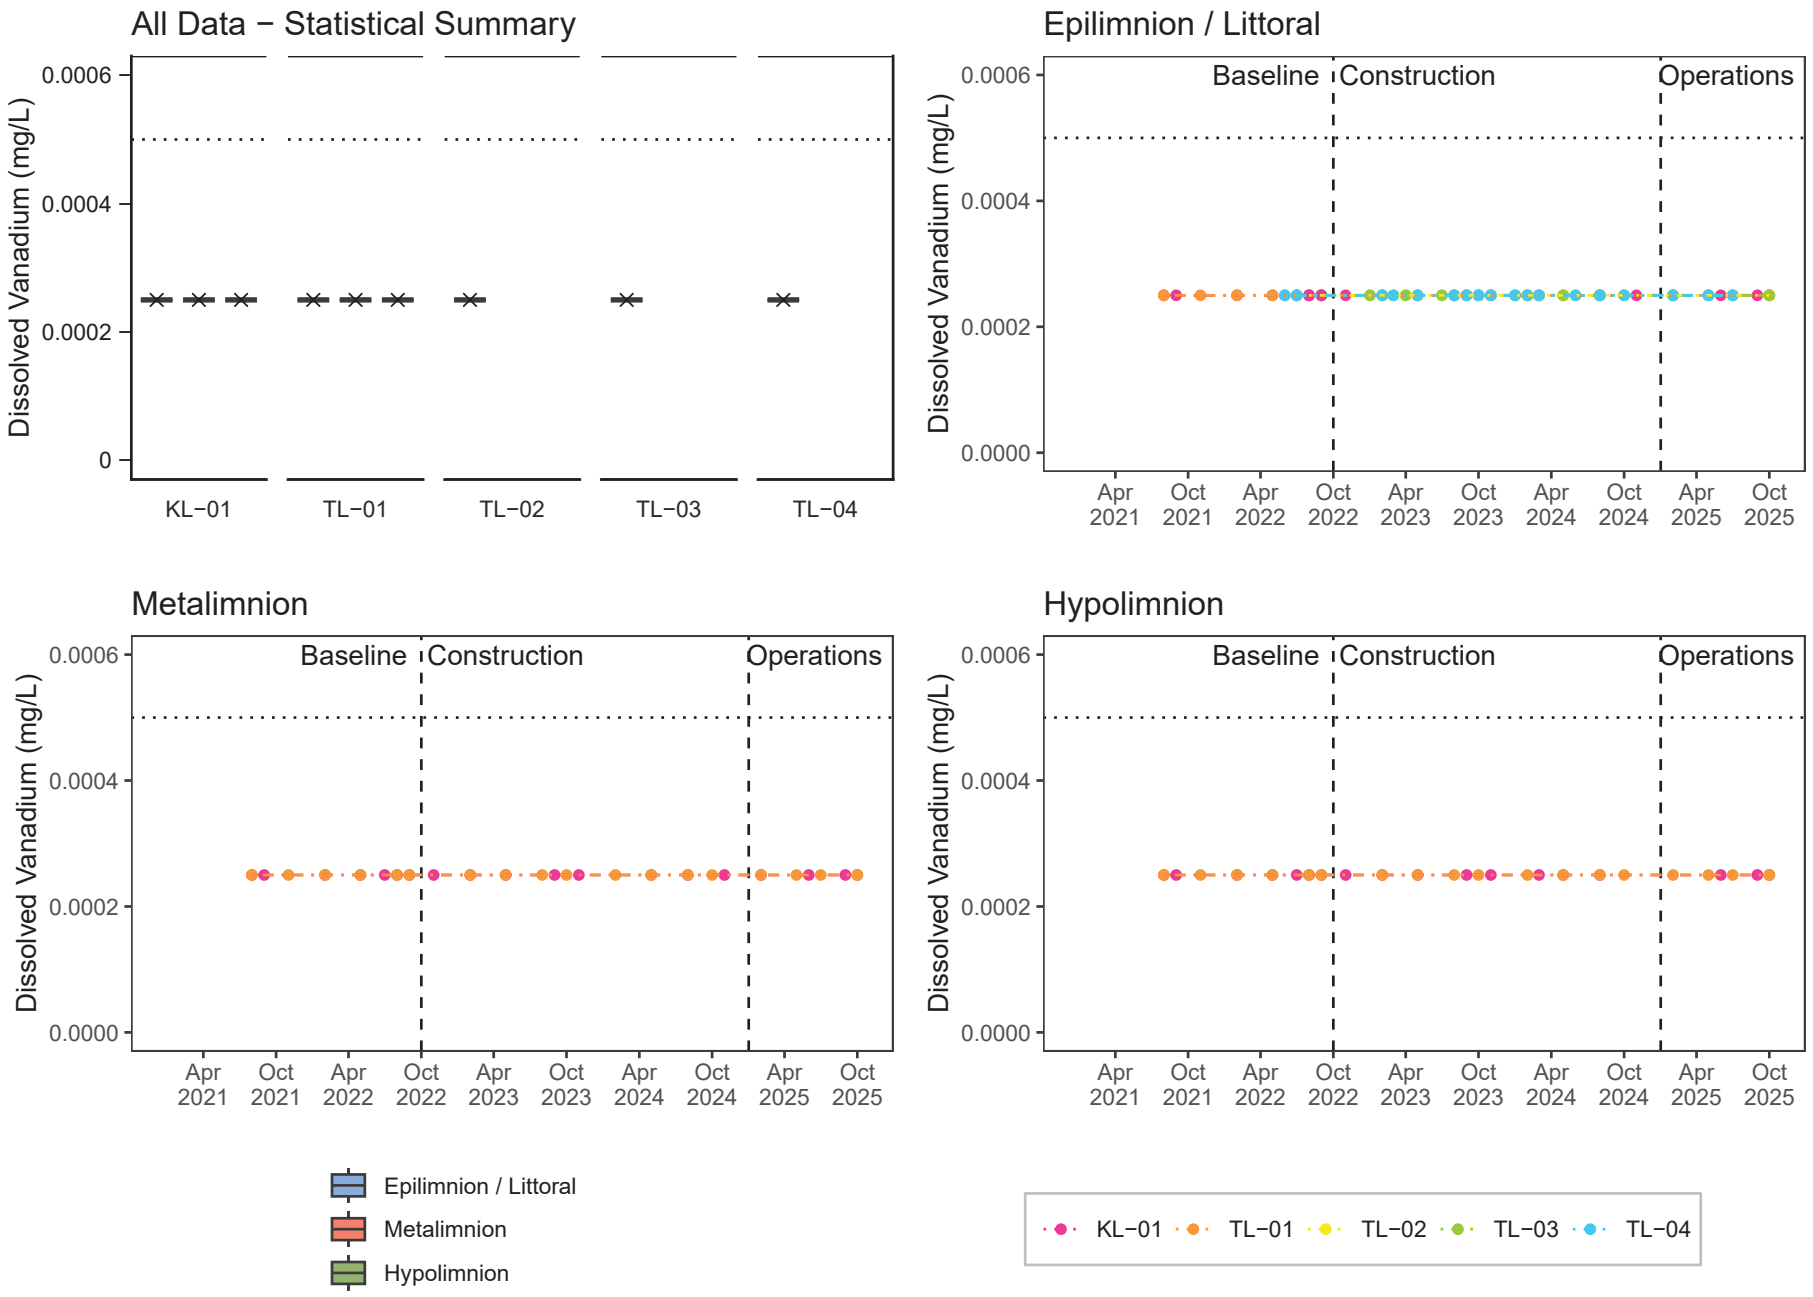
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−84: Dissolved Titanium in AEMP Monitored Lakes, 2021 to 2025



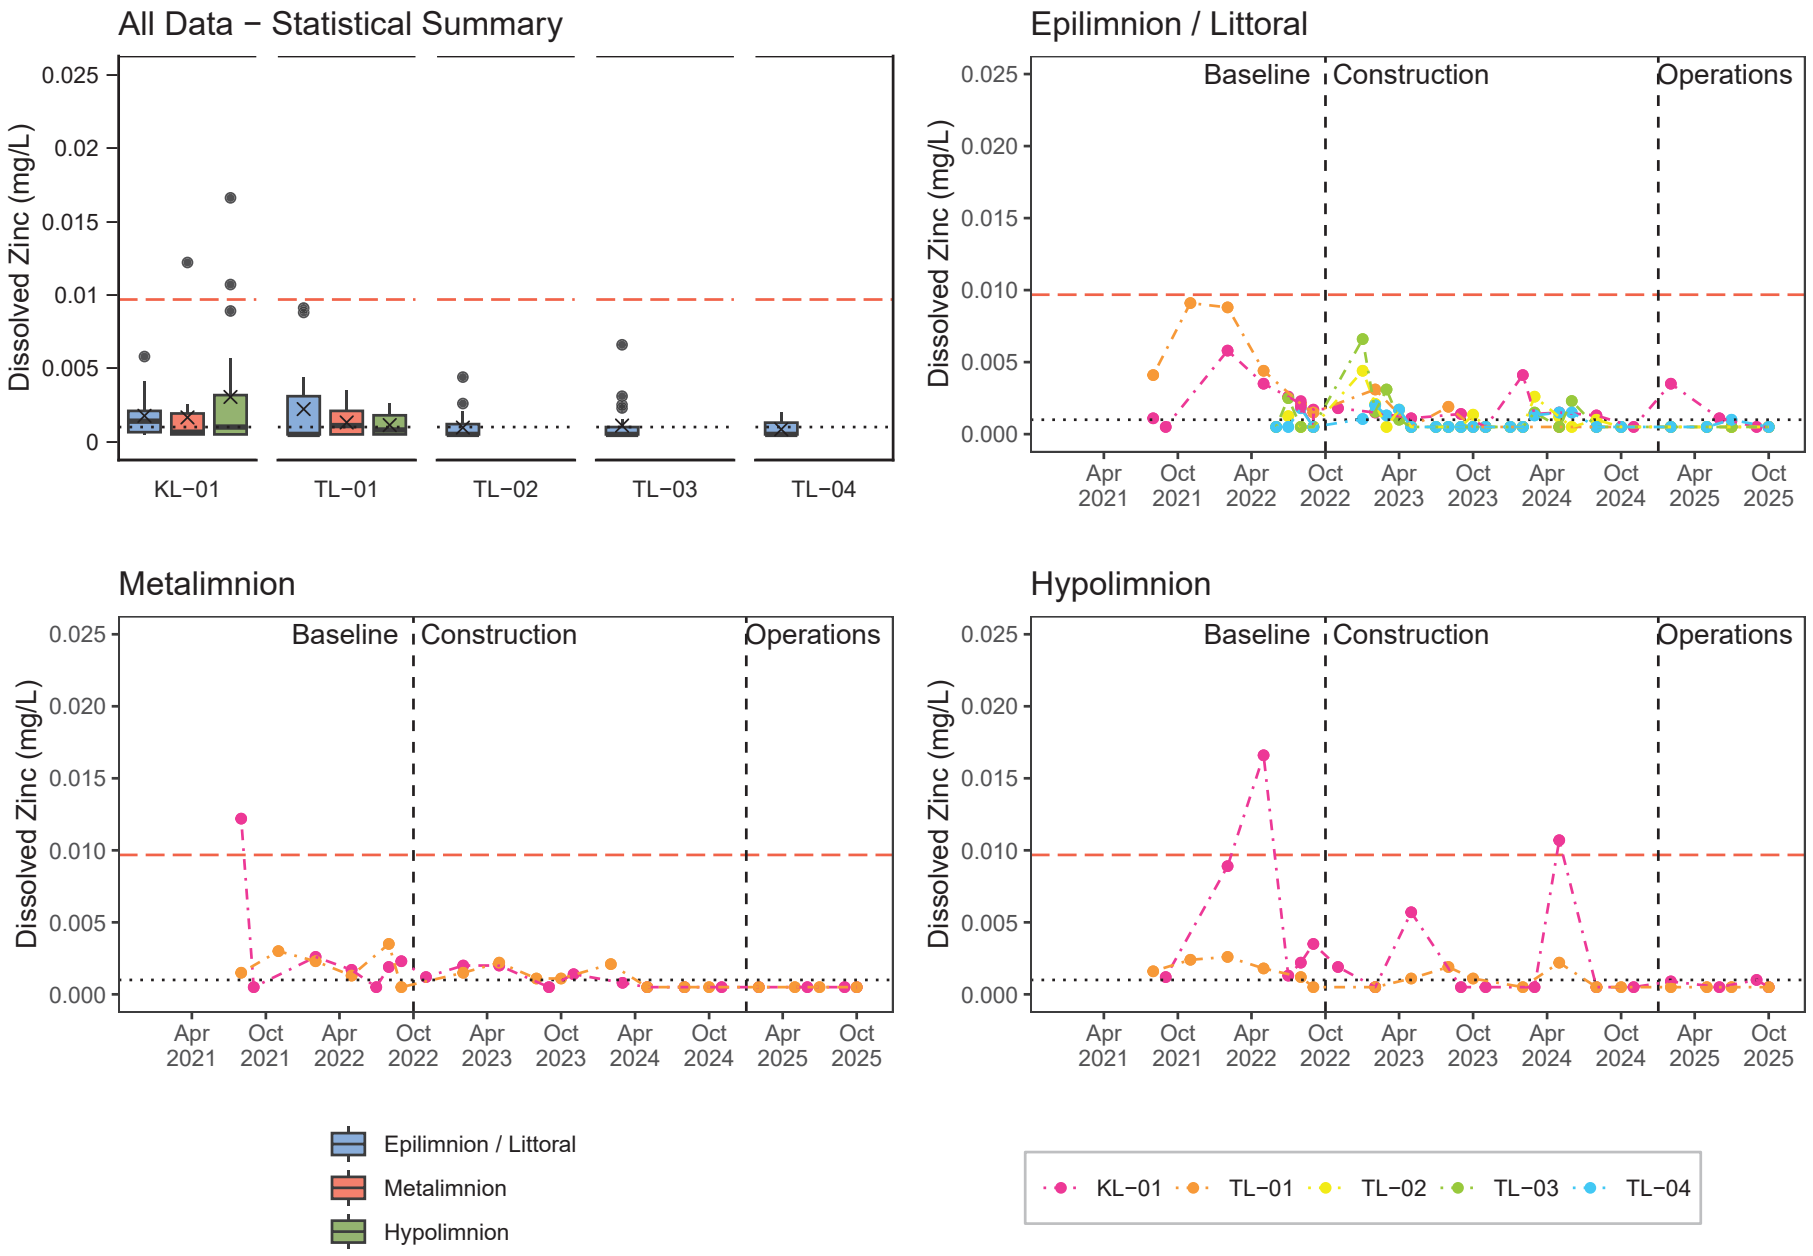
Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−85: Dissolved Uranium in AEMP Monitored Lakes, 2021 to 2025



Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.

Figure A9−86: Dissolved Vanadium in AEMP Monitored Lakes, 2021 to 2025



Notes: Dashed line indicates minimum detection limits.
Concentrations below the detection limit were plotted as half the detection limit.
Median BC WQG−AL long−term chronic guideline for dissolved zinc for Project lakes is 0.0094 mg/L.
Median BC WQG−AL short−term acute guideline for dissolved zinc for Project lakes is 0.0479 mg/L.

Notes:
Concentrations in mg/L (unless otherwise noted).
Shaded cells indicate the mean monthly concentration is greater than the 95th percentile + 20% concentration for that month.
Values below detection limit were replaced with half the detection limit for calculations.

[a] 95th percentile concentration measured in baseline studies at DC-05 and WQ-10 between 2016 and September 30, 2022.

[b] Mean monthly concentration from October 2022 to December 2025, Construction and Operations.

[c] The lower and upper 95th percentile pH value was calculated based on the hydrogen ion concentration + 20%.

Notes:
Concentrations in mg/L (unless otherwise noted).
Shaded cells indicate the mean monthly concentration is greater than the 95th percentile + 20% concentration for that month.
Values below detection limit were replaced with half the detection limit for calculations.

[a] 95th percentile concentration measured in baseline studies between 2016 and September 30, 2022.

[b] Mean monthly concentration from October 2022 to December 2025, Construction and Operations.

[c] The lower and upper 95th percentile pH value was calculated based on the hydrogen ion concentration + 20%.

Notes:
Concentrations in mg/L (unless otherwise noted).
Shaded cells indicate the mean monthly concentration is greater than the 95th percentile + 20% concentration for that month.
Values below detection limit were replaced with half the detection limit for calculations.

[a] 95th percentile concentration measured in baseline studies between 2016 and September 30, 2022.

[b] Mean monthly concentration from October 2022 to December 2025, Construction and Operations.

[c] The lower and upper 95th percentile pH value was calculated based on the hydrogen ion concentration + 20%.

Notes:
Concentrations in mg/L (unless otherwise noted).
Shaded cells indicate the mean monthly concentration is greater than the 95th percentile + 20% concentration for that month.
Values below detection limit were replaced with half the detection limit for calculations.

[a] 95th percentile concentration measured in baseline studies between 2016 and September 30, 2022.

[b] Mean monthly concentration from October 2022 to December 2025, Construction and Operations.

[c] The lower and upper 95th percentile pH value was calculated based on the hydrogen ion concentration + 20%.

Notes:
Concentrations in mg/L (unless otherwise noted).
Shaded cells indicate the mean monthly concentration is greater than the 95th percentile + 20% concentration for that month.
Values below detection limit were replaced with half the detection limit for calculations.

[a] 95th percentile concentration measured in baseline studies between 2016 and September 30, 2022.

[b] Mean monthly concentration from October 2022 to December 2025, Construction and Operations.

[c] The lower and upper 95th percentile pH value was calculated based on the hydrogen ion concentration + 20%.

Notes:
Concentrations in mg/L (unless otherwise noted).
Shaded cells indicate the mean monthly concentration is greater than the 95th percentile + 20% concentration for that month.
Values below detection limit were replaced with half the detection limit for calculations.

[a] 95th percentile concentration measured in baseline studies between 2016 and September 30, 2022.

[b] Mean monthly concentration from October 2022 to December 2025, Construction and Operations.

[c] The lower and upper 95th percentile pH value was calculated based on the hydrogen ion concentration + 20%.

Notes:
Concentrations in mg/L (unless otherwise noted).
Shaded cells indicate the mean monthly concentration is greater than the 95th percentile + 20% concentration for that month.
Values below detection limit were replaced with half the detection limit for calculations.

[a] 95th percentile concentration measured in baseline studies between 2016 and September 30, 2022.

[b] Mean monthly concentration from October 2022 to December 2025, Construction and Operations.

[c] The lower and upper 95th percentile pH value was calculated based on the hydrogen ion concentration + 20%.

Notes:
Concentrations in mg/L (unless otherwise noted).
Shaded cells indicate the mean monthly concentration is greater than the 95th percentile + 20% concentration for that month.
Values below detection limit were replaced with half the detection limit for calculations.

[a] 95th percentile concentration measured in baseline studies between 2016 and September 30, 2022.

[b] Mean monthly concentration from October 2022 to December 2025, Construction and Operations.

[c] The lower and upper 95th percentile pH value was calculated based on the hydrogen ion concentration + 20%.

APPENDIX A-11I: COMPARISON OF AVERAGE MONTHLY WATER QUALITY AND BASELINE FOR 661–20 IN CREEK 661

Parameter	95th Percentile Plus 20% Baseline Concentration[a]

Notes:
Concentrations in mg/L (unless otherwise noted).
Shaded cells indicate the mean monthly concentration is greater than the 95th percentile + 20% concentration for that month.
Values below detection limit were replaced with half the detection limit for calculations.

[a] 95th percentile concentration measured in baseline studies between 2016 and September 30, 2022.

[b] Mean monthly concentration from October 2022 to December 2025, Construction and Operations.

[c] The lower and upper 95th percentile pH value was calculated based on the hydrogen ion concentration + 20%.

Notes:
Concentrations in mg/L (unless otherwise noted).
Shaded cells indicate the mean monthly concentration is greater than the 95th percentile + 20% concentration for that month.
Values below detection limit were replaced with half the detection limit for calculations.

[a] 95th percentile concentration measured in baseline studies between 2016 and September 30, 2022.

[b] Mean monthly concentration from October 2022 to December 2025, Construction and Operations.

[c] The lower and upper 95th percentile pH value was calculated based on the hydrogen ion concentration + 20%.

Notes:
Concentrations in mg/L (unless otherwise noted).
Shaded cells indicate the mean monthly concentration is greater than the 95th percentile + 20% concentration for that month.
Values below detection limit were replaced with half the detection limit for calculations.

[a] 95th percentile concentration measured in baseline studies between 2016 and September 30, 2022.

[b] Mean monthly concentration from October 2022 to December 2025, Construction and Operations.

[c] The lower and upper 95th percentile pH value was calculated based on the hydrogen ion concentration + 20%.

Notes:
Concentrations in mg/L (unless otherwise noted).
Shaded cells indicate the mean monthly concentration is greater than the 95th percentile + 20% concentration for that month.
Values below detection limit were replaced with half the detection limit for calculations.

[a] 95th percentile concentration measured in baseline studies between 2016 and September 30, 2022.

[b] Mean monthly concentration from October 2022 to December 2025, Construction and Operations.

[c] The lower and upper 95th percentile pH value was calculated based on the hydrogen ion concentration + 20%.

Notes:
Concentrations in mg/L (unless otherwise noted).
Shaded cells indicate the mean monthly concentration is greater than the 95th percentile + 20% concentration for that month.
Values below detection limit were replaced with half the detection limit for calculations.

[a] 95th percentile concentration measured in baseline studies between 2016 and September 30, 2022.

[b] Mean monthly concentration from October 2022 to December 2025, Construction and Operations.

[c] The lower and upper 95th percentile pH value was calculated based on the hydrogen ion concentration + 20%.

Appendix A-12 2025 Surface Water Quality Results of the Before-After-Control-Impact Analysis

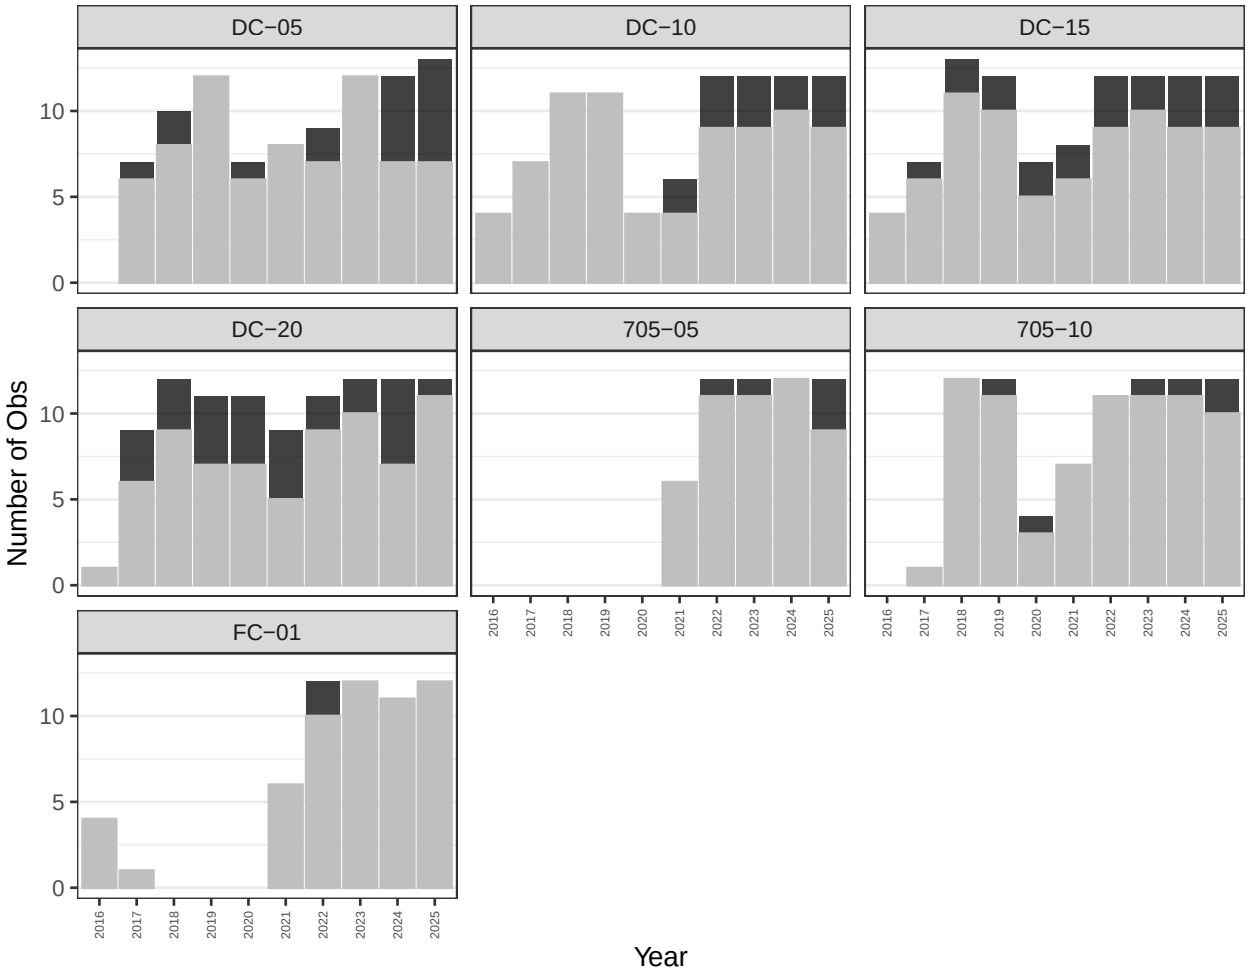
A-12.1 Davidson Creek

A-12.1.1 Total Suspended Solids

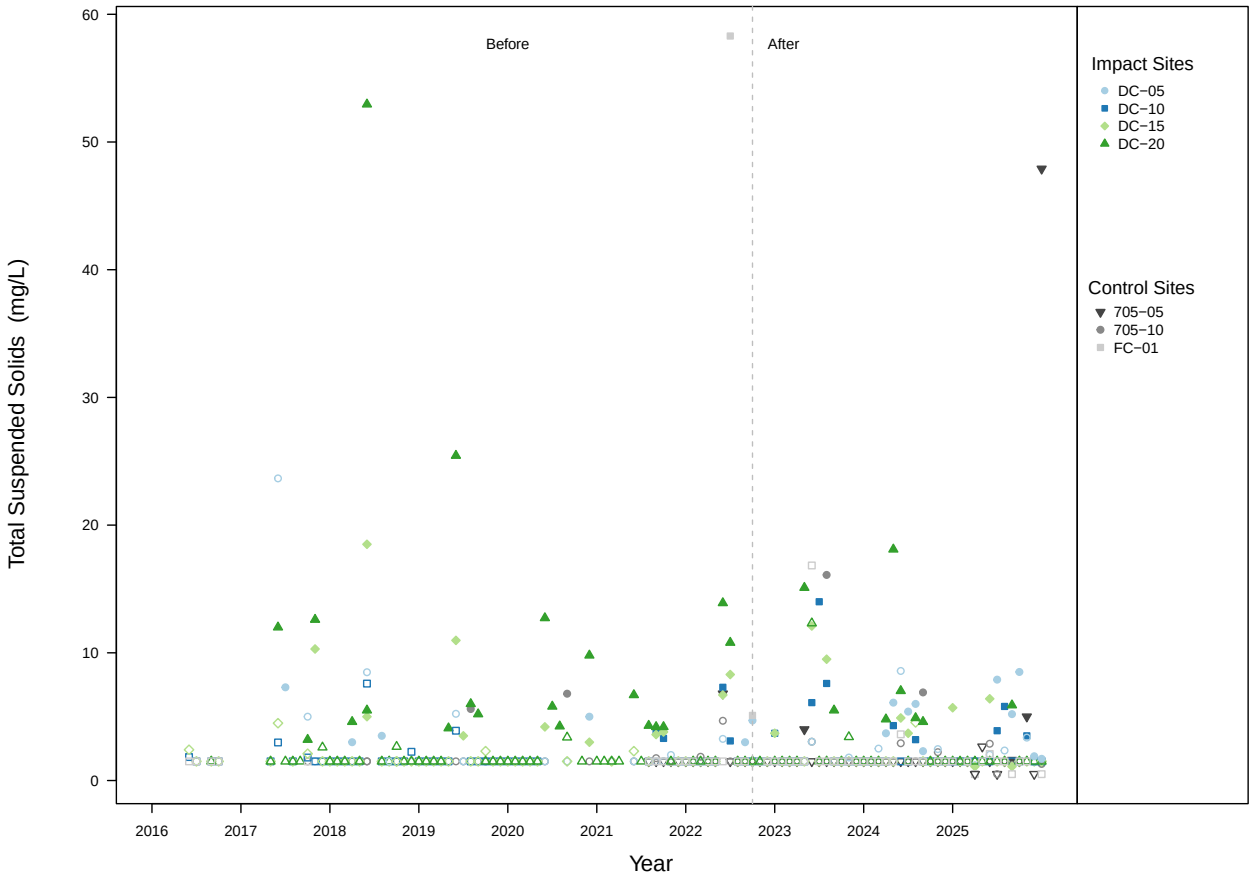
1 Davidson Creek

1.1 Censored Data The following charts indicate the number of measurements taken in each year from each stream that were below the detection limit (light gray) or above the detection limit (dark gray).



Conclusion:

Statistical analyses were not conducted due to censoring or availability of observations. Below is a summary figure of all observations in the dataset.



Note: Open symbols represent cases where the results were below the sample detection limit.

Final Summary Table

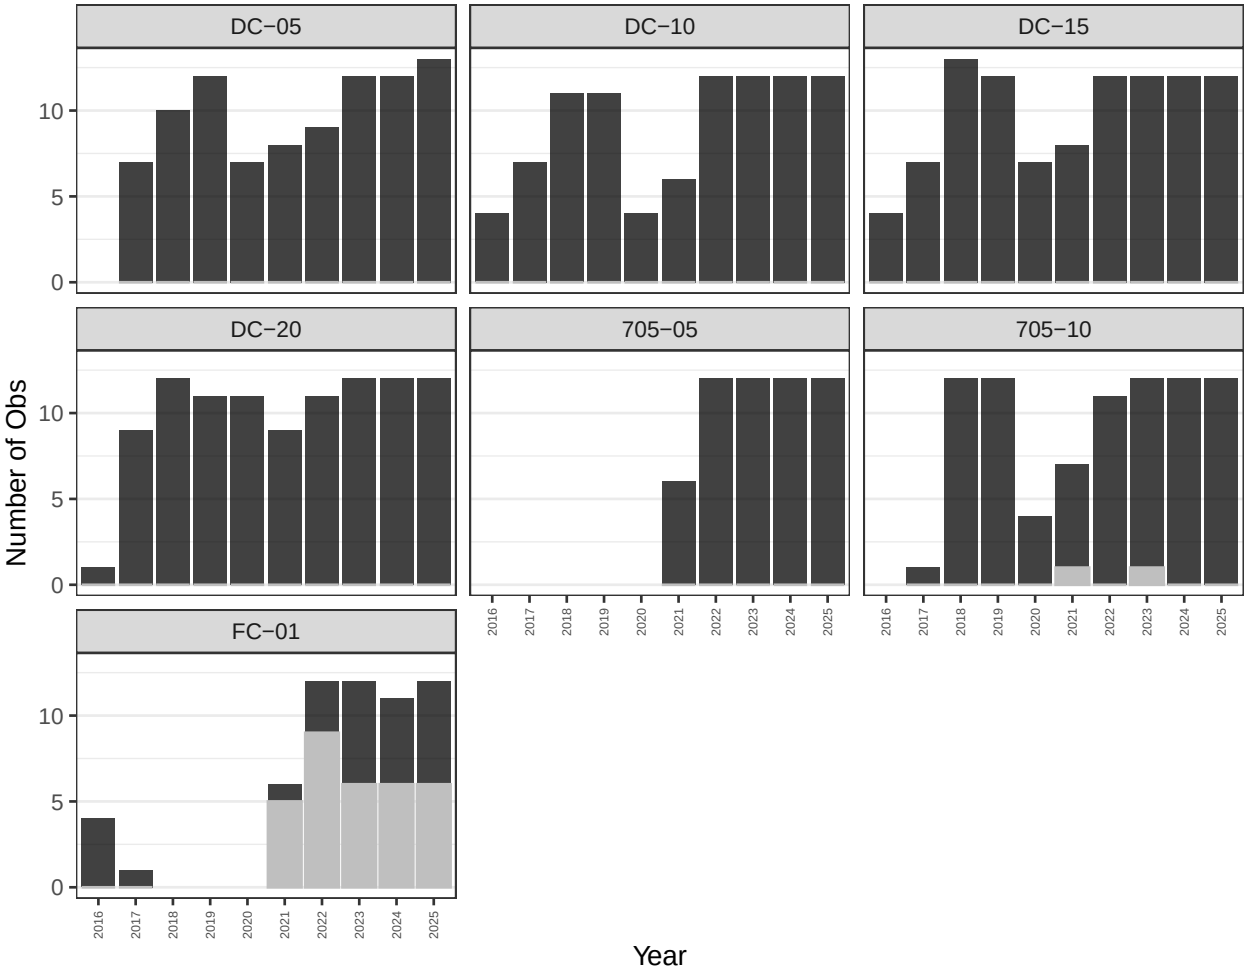
Variable	Total Suspended Solids
Watershed	Davidson Creek
Waterbody	Stream
Streams Removed	All Excluded
Data Transformation	N/A
Model Type	N/A
Benchmark	None
Significant BACI term	N/A

A-12.1.2 Turbidity

1 Davidson Creek

1.1 Censored Data

The following charts indicate the number of measurements taken in each year from each stream that were below the detection limit (light gray) or above the detection limit (dark gray).



Observations at or below the analytical detection limit were considered censored. Data were excluded from the analysis if greater than 70% of observations from a site were censored or if greater than 50% of observations in a site's sampling year were censored. If more than 10% of observations from a site in a sampling year were censored, data were flagged to caution interpretation of results. The following observations were excluded:

Watershed	Site	Year	Class	Period	#Obs Removed
Fawnie Creek (Control)	FC-01	2021	control	before	6
Fawnie Creek (Control)	FC-01	2022	control	before	12
Fawnie Creek (Control)	FC-01	2022	control	after	12
Fawnie Creek (Control)	FC-01	2024	control	after	11

1.2 Sample Sizes for Modelling

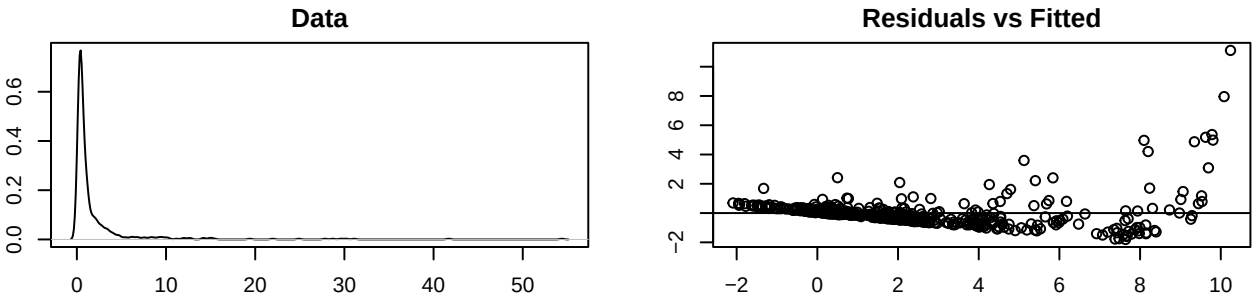
The remaining sample sizes per site and period are summarised in the table below.

Watershed	Site	Period	N	Median	% Censored
Davidson Creek	DC-05	before	51	0.3925	0.000
Davidson Creek	DC-05	after	39	3.1900	0.000
Davidson Creek	DC-10	before	52	0.3400	0.000
Davidson Creek	DC-10	after	39	2.7400	0.000
Davidson Creek	DC-15	before	60	0.3740	0.000
Davidson Creek	DC-15	after	39	1.6200	0.000
Davidson Creek	DC-20	before	62	0.5950	0.000
Davidson Creek	DC-20	after	38	2.2635	0.000
Creek 705 (Control)	705-05	before	15	0.7400	0.000
Creek 705 (Control)	705-05	after	39	0.8050	0.000
Creek 705 (Control)	705-10	before	45	0.6000	2.222
Creek 705 (Control)	705-10	after	38	0.5450	2.632
Fawnie Creek (Control)	FC-01	before	5	0.2200	0.000
Fawnie Creek (Control)	FC-01	after	24	0.1150	50.000

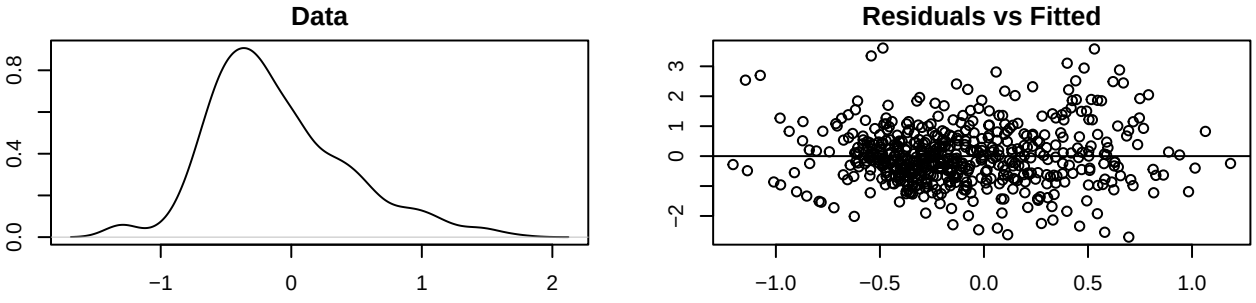
1.3 Initial Model Fit

Initially a model was fit to all sites to assess the need for transformations.

Natural Scale Model



Log−10 Transformed Model



Outliers

The following is a summary of outliers identified (if any) using preliminary regression models. All data points were plotted in the summary figures. The analysis needs to be interpreted with care and in conjunction with graphical displays if large outliers are present.

Outliers on natural scale:

Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Davidson Creek	DC-05	2024	3	impact	after	54.40	10.242	11.113	Y
Davidson Creek	DC-20	2024	3	impact	after	41.70	10.083	7.957	Y
Davidson Creek	DC-05	2024	4	impact	after	31.10	9.783	5.364	Y
Davidson Creek	DC-20	2024	4	impact	after	30.20	9.624	5.178	Y
Davidson Creek	DC-10	2024	3	impact	after	29.60	9.805	4.981	Y
Davidson Creek	DC-05	2024	2	impact	after	27.83	8.097	4.967	Y
Davidson Creek	DC-10	2024	4	impact	after	28.70	9.347	4.870	Y
Davidson Creek	DC-20	2024	12	impact	after	24.90	8.200	4.203	Y
Davidson Creek	DC-15	2025	6	impact	after	19.40	5.123	3.593	Y
Davidson Creek	DC-05	2024	5	impact	after	21.97	9.694	3.089	Y

Outliers on log scale:

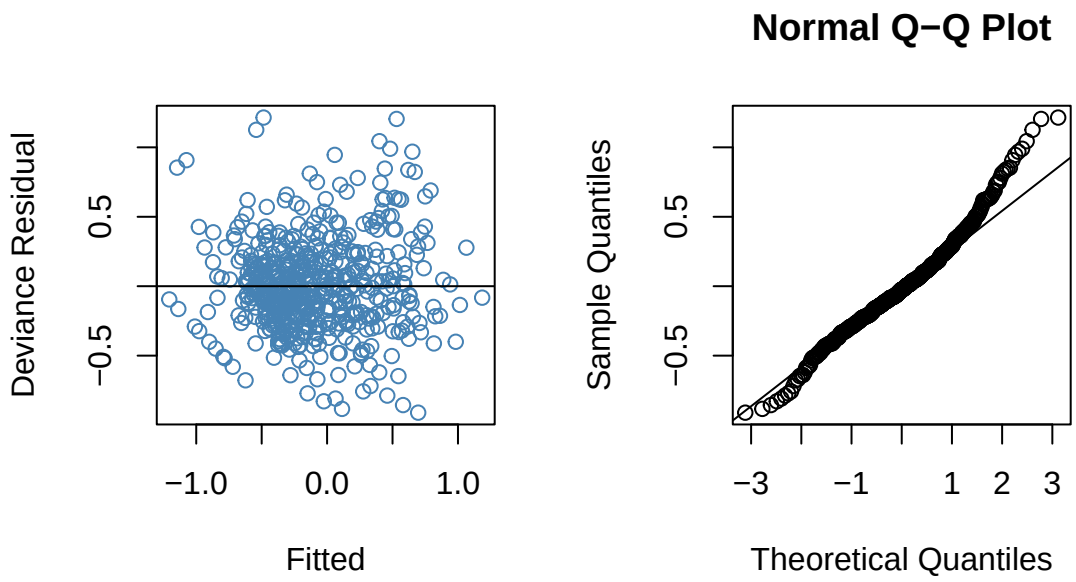
Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Creek 705 (Control)	705-10	2023	7	control	after	0.7292	-0.4855	3.609	Y
Davidson Creek	DC-05	2024	3	impact	after	1.7356	0.5309	3.579	Y
Fawnie Creek (Control)	FC-01	2023	5	control	after	0.5846	-0.5418	3.347	Y
Davidson Creek	DC-05	2024	2	impact	after	1.4446	0.4001	3.103	Y

Based on examination of the residuals, the log-10 transformed data were selected for analysis. No outliers were removed prior to analysis.

1.4 Before-After Control-Impact Linear Modeling

A models was fit to compare impact sites with control sites.

Plot of Standardized Residuals and Fitted Values



Results of the ANOVA test on the fixed effects of the model:

	Sum Sq.	Mean Sq.	NumDF	DenDF	F value	p	p adjusted
class	0.3454	0.3454	1	5.06	3.050	0.14	
period	1.0835	1.0835	1	274.36	9.565	0.00219	
class:period	10.0142	10.0142	1	520.94	88.408	<0.001	7.23e-18

Results of the observed power calculation for the between-effect test on the fixed effects for repeated-measures ANOVA analysis at a significance level of 0.05:

Sample Size	Effect Size (f2)	Expected Power	Power Test
546	0.1845	96%	Repeated-Measures ANOVA

Summary of BACI contrasts for relative difference between changes from the *before* to *after* in impact sites (DC-05, DC-10, DC-15, DC-20) and control sites (705-05, 705-10, FC-01), with p value adjusted for multiple comparisons:

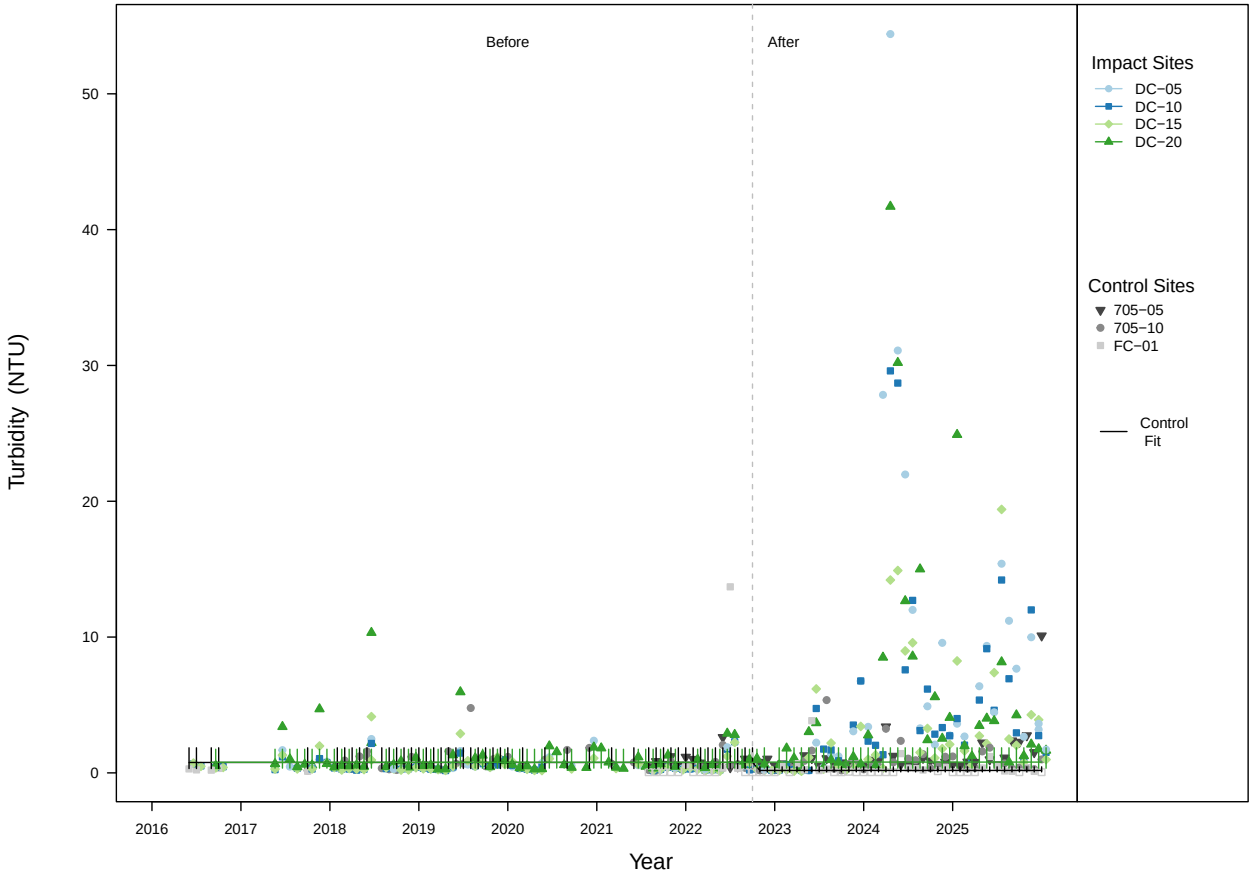
Impact vs.	Estimate	Significance
control sites	0.6367	significant

Conclusion:

The change in Turbidity concentrations at the impact sites from *before* to *after* was significantly (*adjusted p* = 7.23×10^{-18}) different from the change at the control sites, according to the test on the BACI term (*class:period*).

1.5 Model Summary

The overall performance of the model is shown in the plot below. All the observations are plotted along with the model estimates. The model fitted values and 95% confidence intervals are indicated as lines and errors.



Note: Open symbols represent cases where the results were below the sample detection limit. Model fitted values are based on site class and period. Error bars indicate 95% confidence intervals. The positions of data along the x-axis are adjusted for legibility. Modelled log-transformed values were converted back to natural scale.

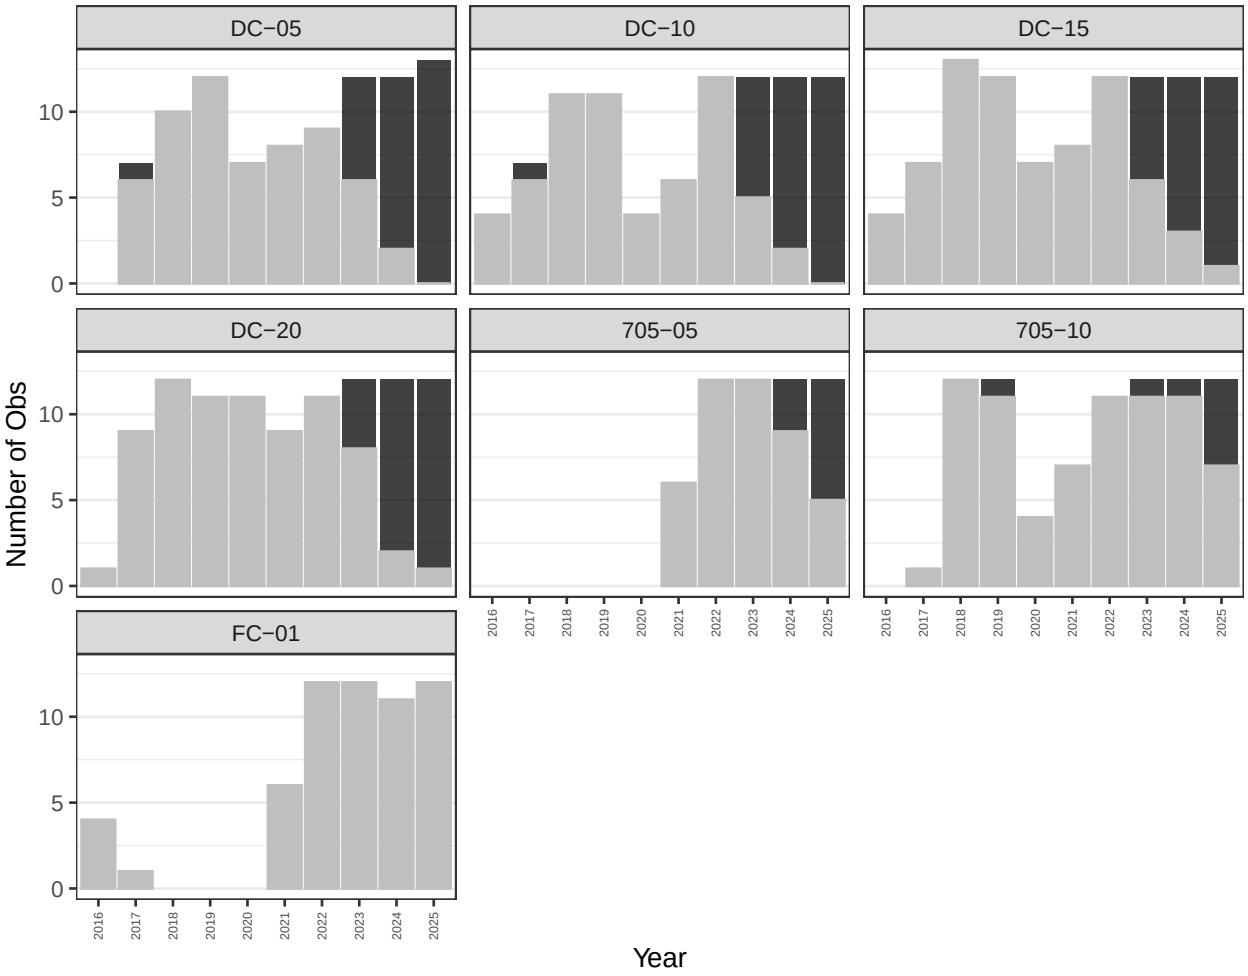
Final Summary Table

Variable	Turbidity
Watershed	Davidson Creek
Waterbody	Stream
Streams Removed	None
Data Transformation	Log-10 transformed
Model Type	Linear Mixed Effects Regression
Is BACI significant	Yes

A-12.1.3 Chloride

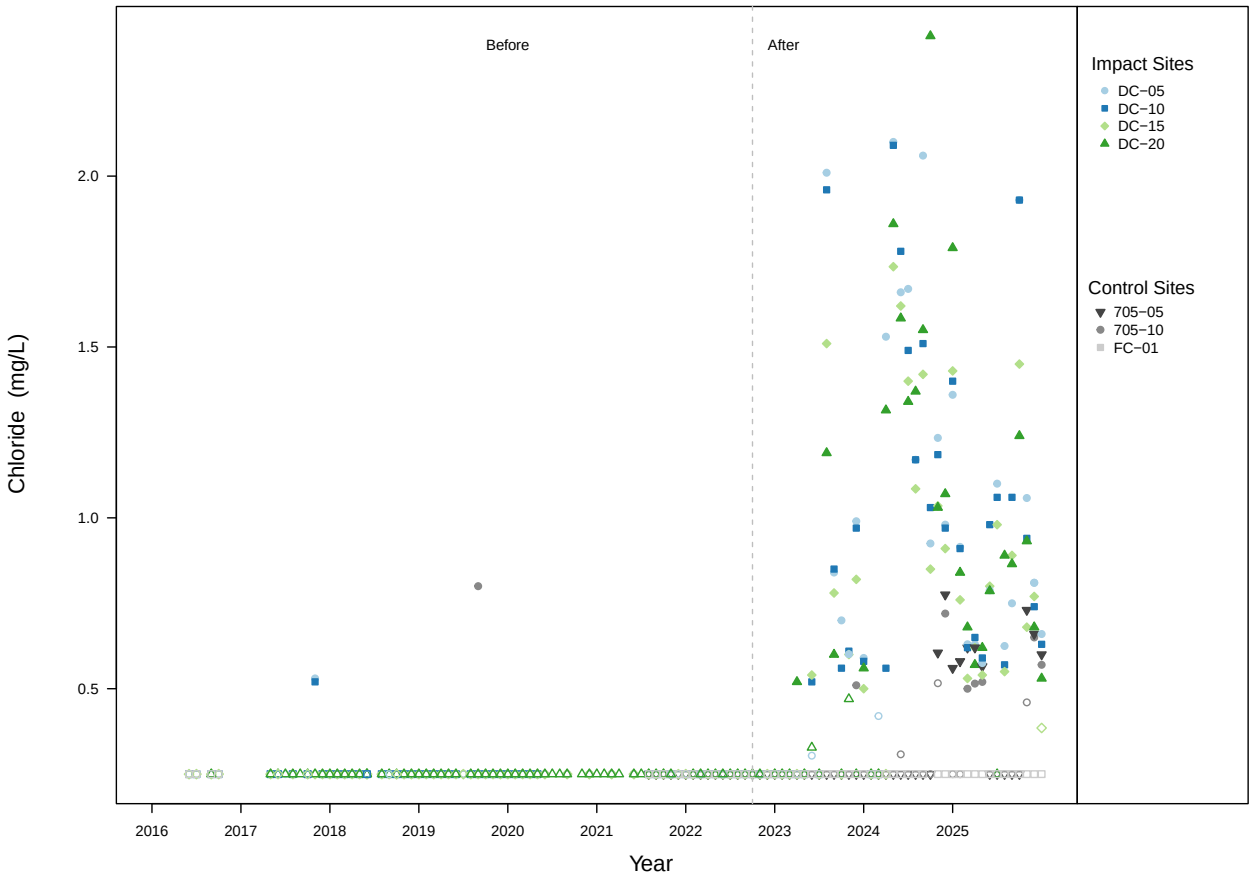
1 Davidson Creek

1.1 Censored Data The following charts indicate the number of measurements taken in each year from each stream that were below the detection limit (light gray) or above the detection limit (dark gray).



Conclusion:

Statistical analyses were not conducted due to censoring or availability of observations. Below is a summary figure of all observations in the dataset.



Note: Open symbols represent cases where the results were below the sample detection limit.

Final Summary Table

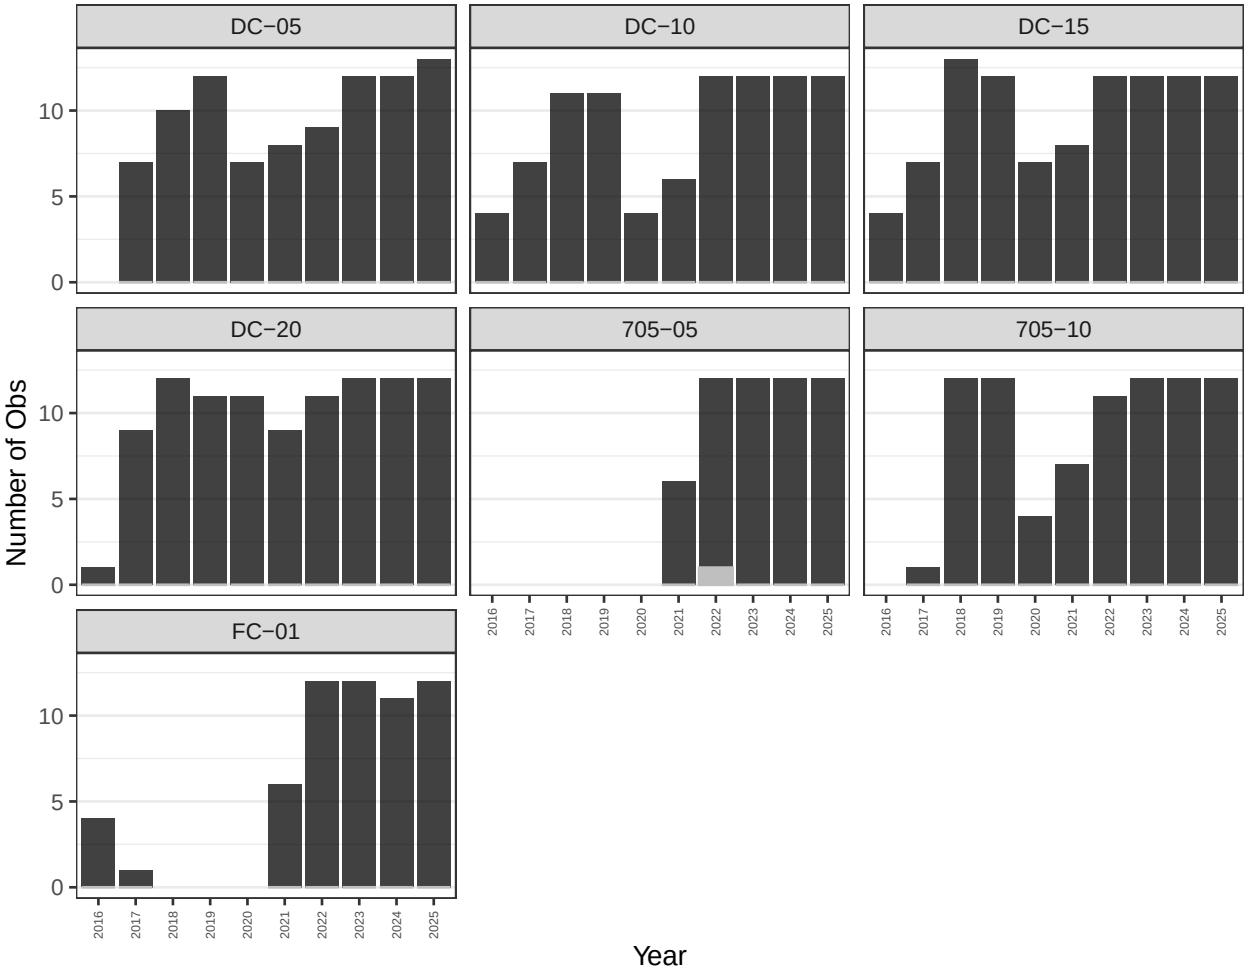
Variable	Chloride
Watershed	Davidson Creek
Waterbody	Stream
Streams Removed	All Excluded
Data Transformation	N/A
Model Type	N/A
Benchmark	None
Significant BACI term	N/A

A-12.1.4 Sulphate

1 Davidson Creek

1.1 Censored Data

The following charts indicate the number of measurements taken in each year from each stream that were below the detection limit (light gray) or above the detection limit (dark gray).



Observations at or below the analytical detection limit were considered censored. Data were excluded from the analysis if greater than 70% of observations from a site were censored or if greater than 50% of observations in a site's sampling year were censored. If more than 10% of observations from a site in a sampling year were censored, data were flagged to caution interpretation of results. The following observations were excluded:

None

1.2 Sample Sizes for Modelling

The remaining sample sizes per site and period are summarised in the table below.

Watershed	Site	Period	N	Median	% Censored
Davidson Creek	DC-05	before	51	1.870	0.000
Davidson Creek	DC-05	after	39	3.290	0.000
Davidson Creek	DC-10	before	52	1.950	0.000
Davidson Creek	DC-10	after	39	3.340	0.000
Davidson Creek	DC-15	before	60	1.940	0.000
Davidson Creek	DC-15	after	39	3.130	0.000
Davidson Creek	DC-20	before	62	1.825	0.000
Davidson Creek	DC-20	after	38	2.955	0.000
Creek 705 (Control)	705-05	before	15	0.560	6.667
Creek 705 (Control)	705-05	after	39	1.050	0.000
Creek 705 (Control)	705-10	before	45	1.090	0.000

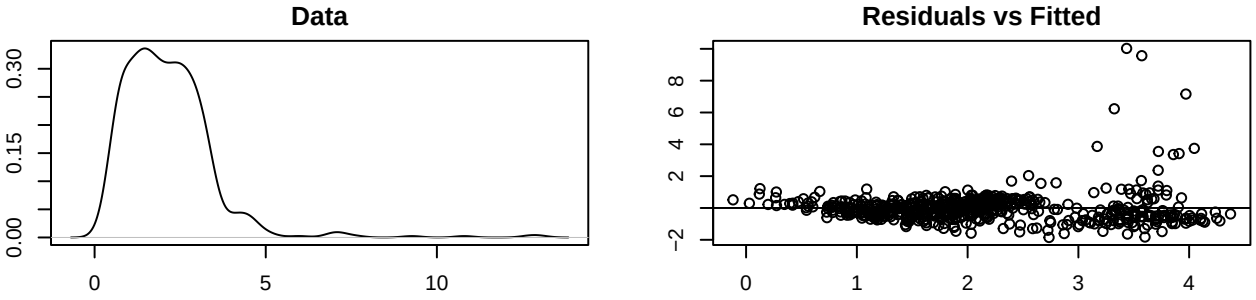
Fawnie Creek (Control)	FC-01	after	38	2.346	0.000

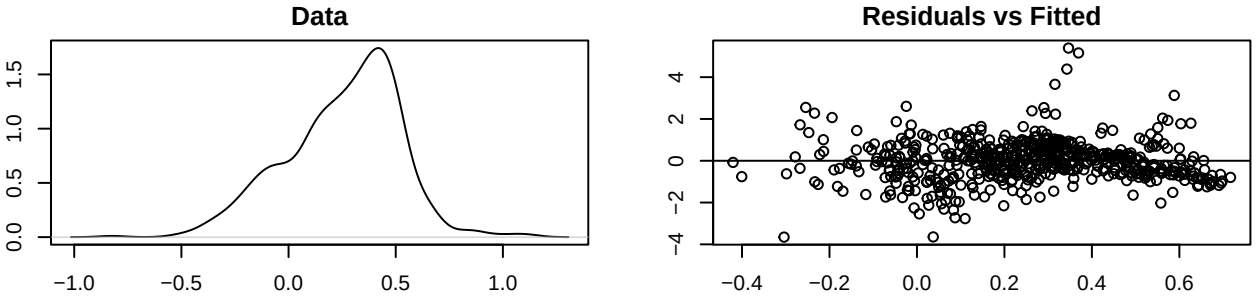
1.3 Initial Model Fit

Initially a model was fit to all sites to assess the need for transformations.

Natural Scale Model



Log−10 Transformed Model



Outliers

The following is a summary of outliers identified (if any) using preliminary regression models. All data points were plotted in the summary figures. The analysis needs to be interpreted with care and in conjunction with graphical displays if large outliers are present.

Outliers on natural scale:

Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Davidson Creek	DC-05	2023	7	impact	after	13.00	3.435	10.026	Y
Davidson Creek	DC-10	2023	7	impact	after	12.70	3.572	9.568	Y
Davidson Creek	DC-10	2025	9	impact	after	10.80	3.971	7.159	Y
Davidson Creek	DC-15	2023	7	impact	after	9.27	3.324	6.233	Y
Davidson Creek	DC-20	2023	7	impact	after	6.86	3.170	3.868	Y
Davidson Creek	DC-10	2025	12	impact	after	7.62	4.046	3.746	Y
Davidson Creek	DC-15	2025	9	impact	after	7.11	3.723	3.551	Y
Davidson Creek	DC-05	2025	12	impact	after	7.17	3.909	3.418	Y
Davidson Creek	DC-10	2025	11	impact	after	7.06	3.858	3.357	Y

Outliers on log scale:

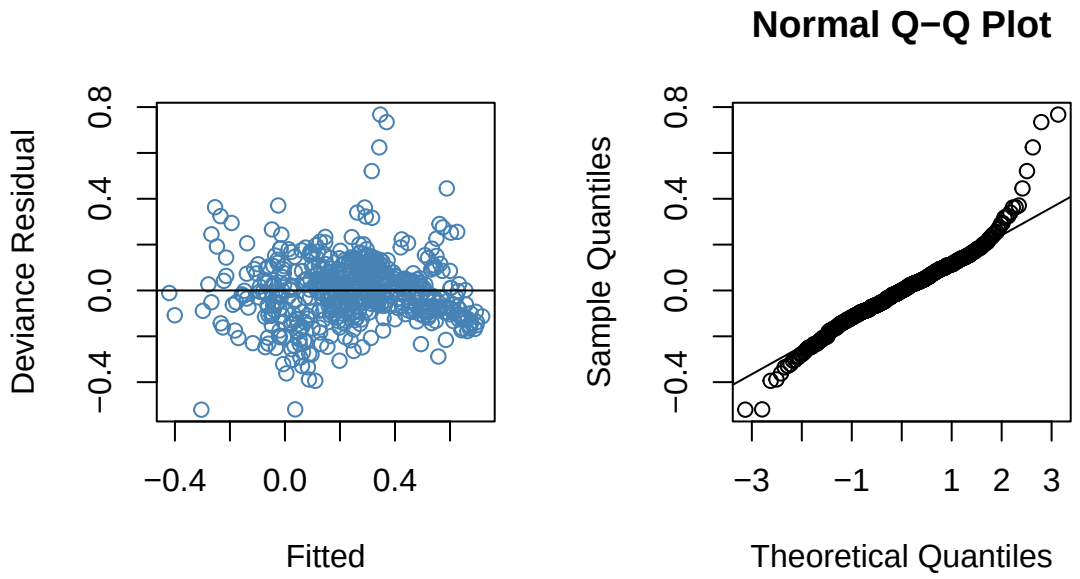
Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Davidson Creek	DC-05	2023	7	impact	after	1.1139	0.3465	5.392	Y
Davidson Creek	DC-10	2023	7	impact	after	1.1038	0.3694	5.160	Y
Davidson Creek	DC-15	2023	7	impact	after	0.9671	0.3428	4.386	Y
Davidson Creek	DC-20	2023	7	impact	after	0.8363	0.3156	3.659	Y
Creek 705 (Control)	705-05	2022	7	control	before	-0.8239	-0.3039	-3.654	N
Creek 705 (Control)	705-05	2025	9	control	after	-0.4815	0.0372	-3.644	Y
Davidson Creek	DC-10	2025	9	impact	after	1.0334	0.5883	3.127	Y

Based on examination of the residuals, the log-10 transformed data were selected for analysis. No outliers were removed prior to analysis.

1.4 Before-After Control-Impact Linear Modeling

A models was fit to compare impact sites with control sites.

Plot of Standardized Residuals and Fitted Values



Results of the ANOVA test on the fixed effects of the model:

	Sum Sq.	Mean Sq.	NumDF	DenDF	F value	p	p adjusted
class	0.1675	0.1675	1	5.026	8.266	0.0346	
period	0.8639	0.8639	1	25.678	42.646	<0.001	
class:period	0.5325	0.5325	1	555.531	26.287	<0.001	1.59e-06

Results of the observed power calculation for the between-effect test on the fixed effects for repeated-measures ANOVA analysis at a significance level of 0.05:

Sample Size	Effect Size (f2)	Expected Power	Power Test
575	0.4481	100%	Repeated-Measures ANOVA

Summary of BACI contrasts for relative difference between changes from the *before* to *after* in impact sites (DC-05, DC-10, DC-15, DC-20) and control sites (705-05, 705-10, FC-01), with p value adjusted for multiple comparisons:

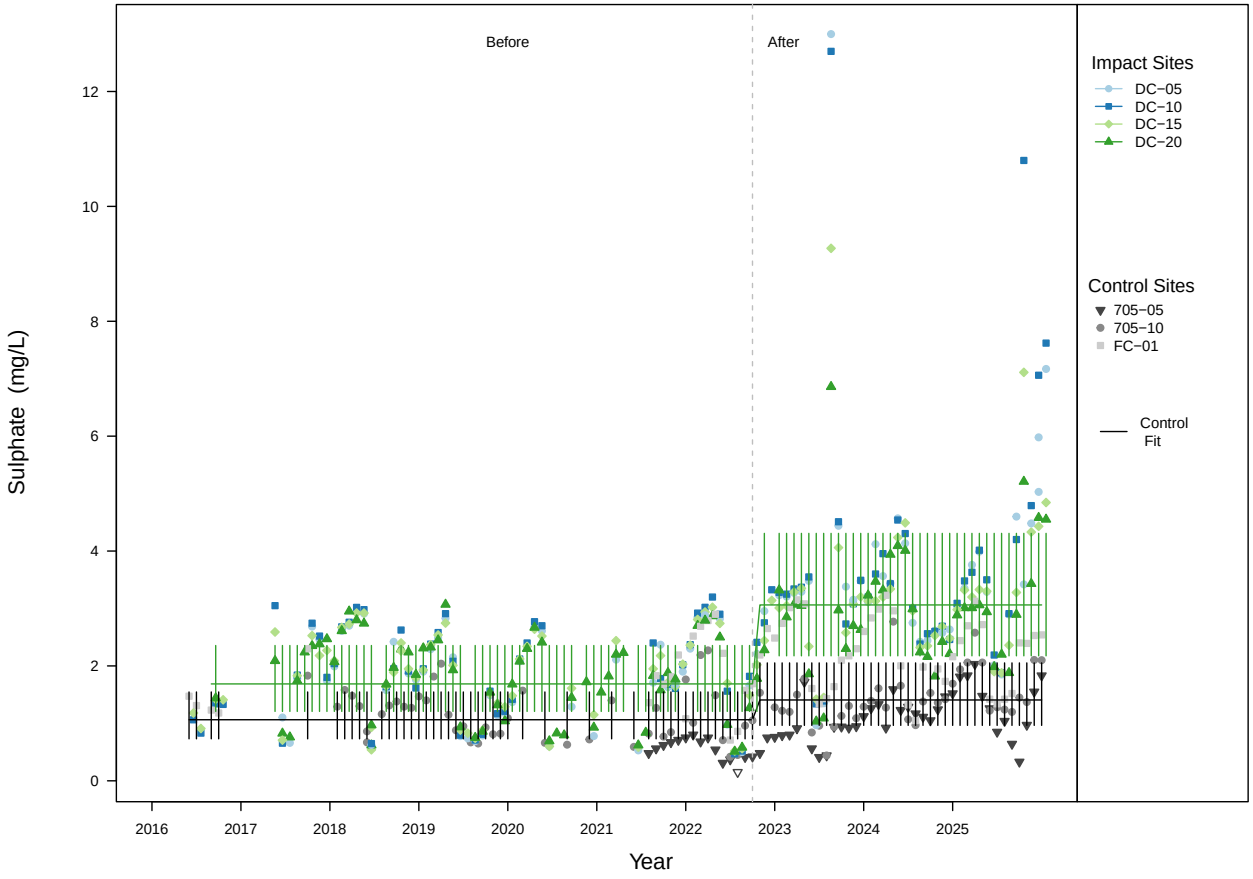
Impact vs.	Estimate	Significance
control sites	0.1371	significant

Conclusion:

The change in Sulphate concentrations at the impact sites from *before* to *after* was significantly (*adjusted p* = 1.59×10^{-6}) different from the change at the control sites, according to the test on the BACI term (*class:period*).

1.5 Model Summary

The overall performance of the model is shown in the plot below. All the observations are plotted along with the model estimates. The model fitted values and 95% confidence intervals are indicated as lines and errors.



Note: Open symbols represent cases where the results were below the sample detection limit. Model fitted values are based on site class and period. Error bars indicate 95% confidence intervals. The positions of data along the x-axis are adjusted for legibility. Modelled log-transformed values were converted back to natural scale.

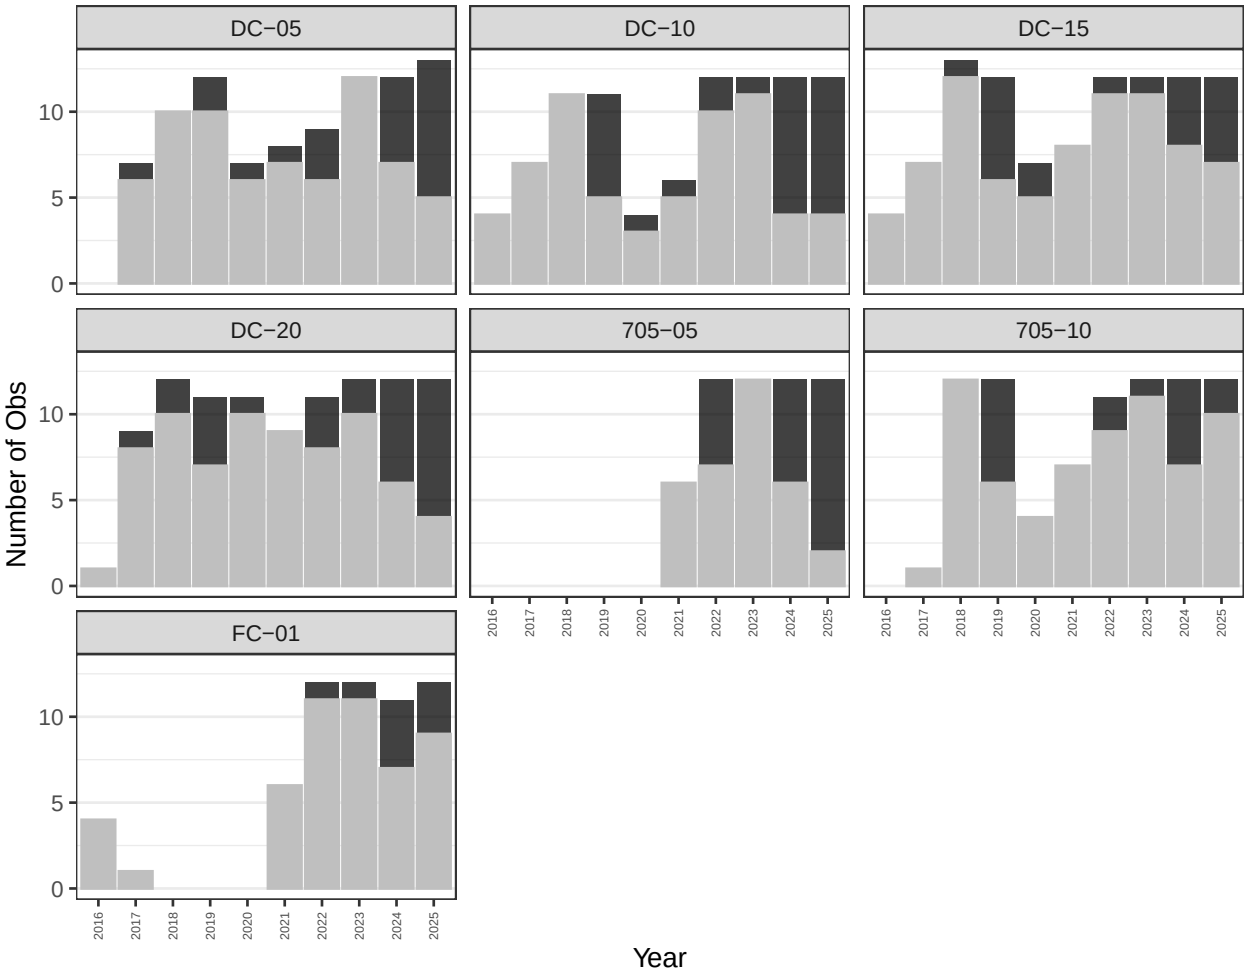
Final Summary Table

Variable	Sulphate
Watershed	Davidson Creek
Waterbody	Stream
Streams Removed	None
Data Transformation	Log-10 transformed
Model Type	Linear Mixed Effects Regression
Is BACI significant	Yes

A-12.1.5 Ammonia

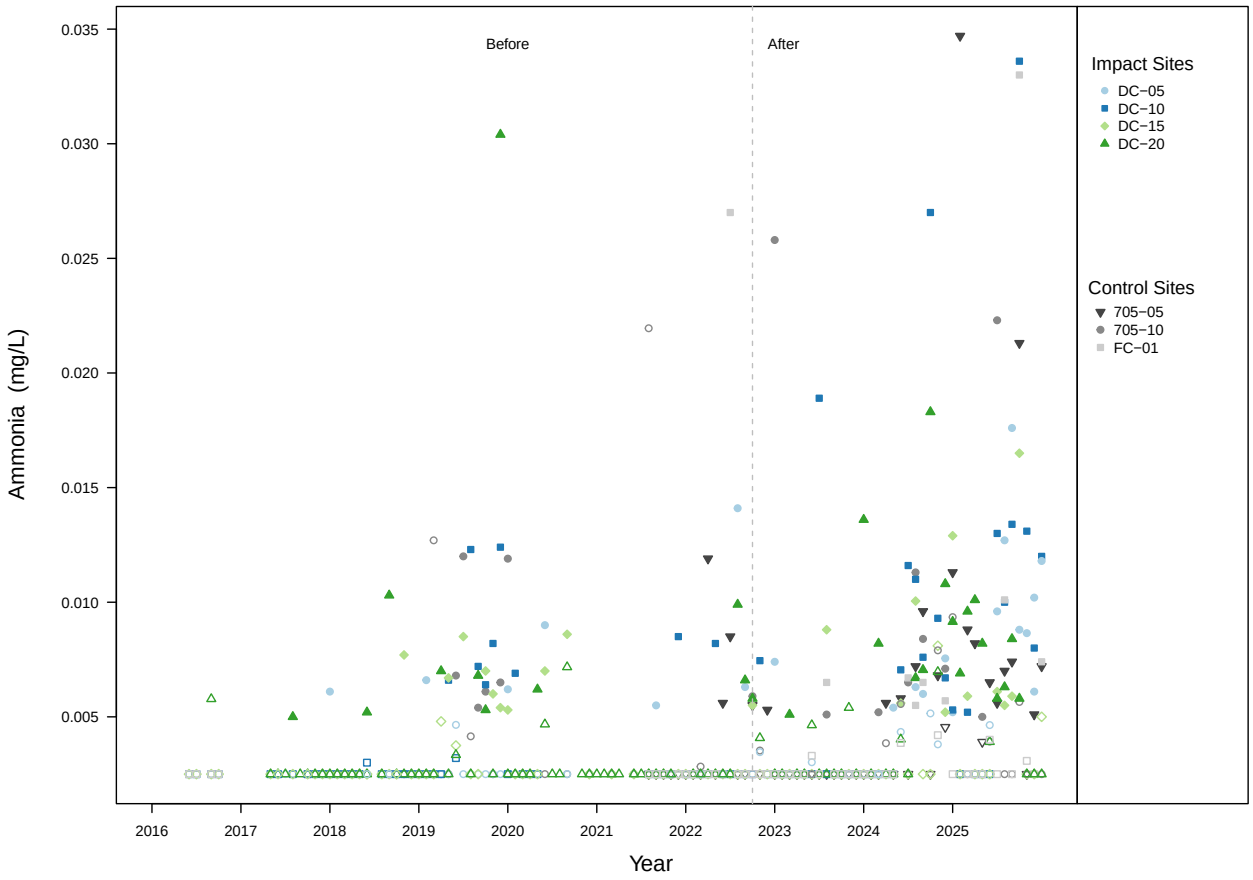
1 Davidson Creek

1.1 Censored Data The following charts indicate the number of measurements taken in each year from each stream that were below the detection limit (light gray) or above the detection limit (dark gray).



Conclusion:

Statistical analyses were not conducted due to censoring or availability of observations. Below is a summary figure of all observations in the dataset.



Note: Open symbols represent cases where the results were below the sample detection limit.

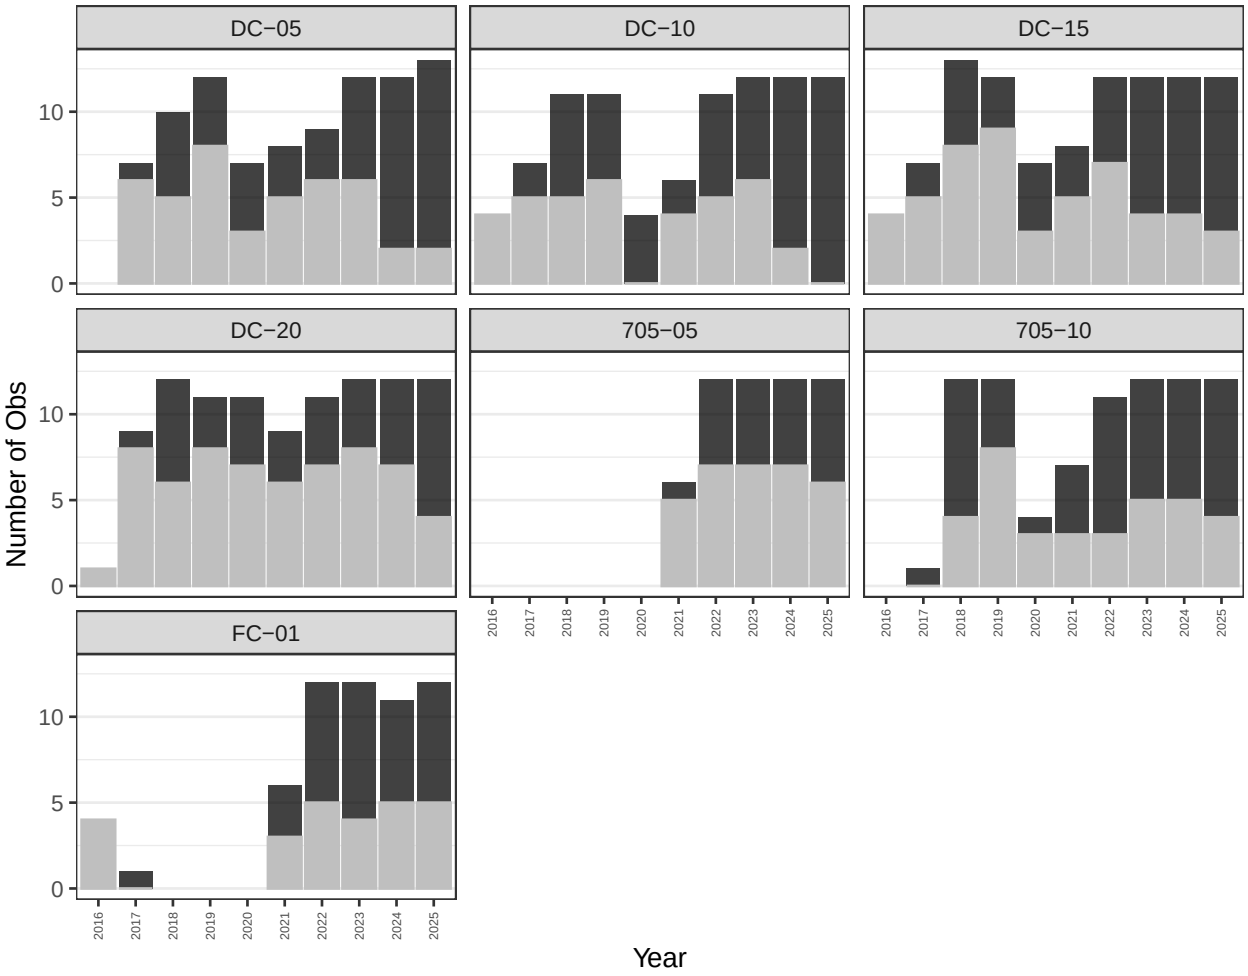
Final Summary Table

Variable	Ammonia
Watershed	Davidson Creek
Waterbody	Stream
Streams Removed	All Excluded
Data Transformation	N/A
Model Type	N/A
Benchmark	None
Significant BACI term	N/A

A-12.1.6 Nitrate-N

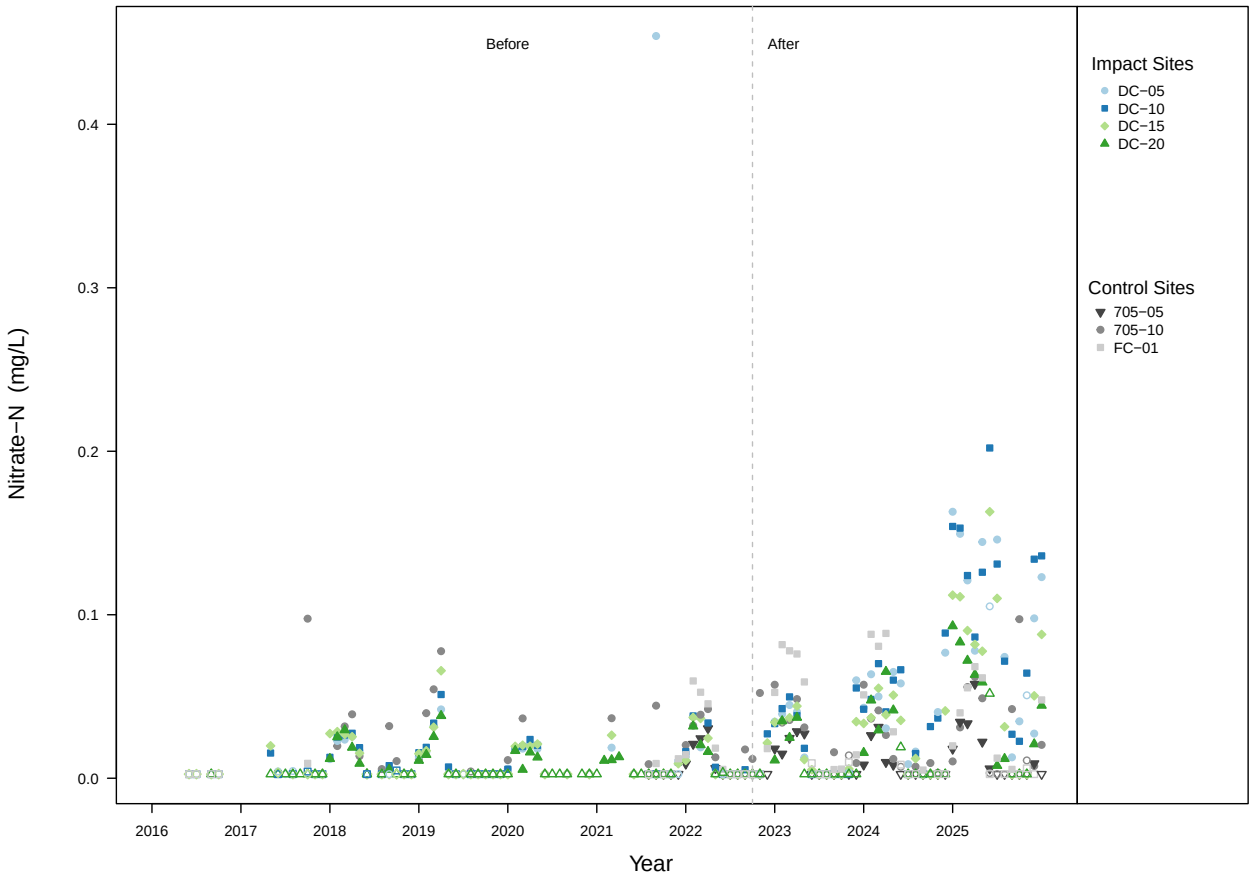
1 Davidson Creek

1.1 Censored Data The following charts indicate the number of measurements taken in each year from each stream that were below the detection limit (light gray) or above the detection limit (dark gray).



Conclusion:

Statistical analyses were not conducted due to censoring or availability of observations. Below is a summary figure of all observations in the dataset.



Note: Open symbols represent cases where the results were below the sample detection limit.

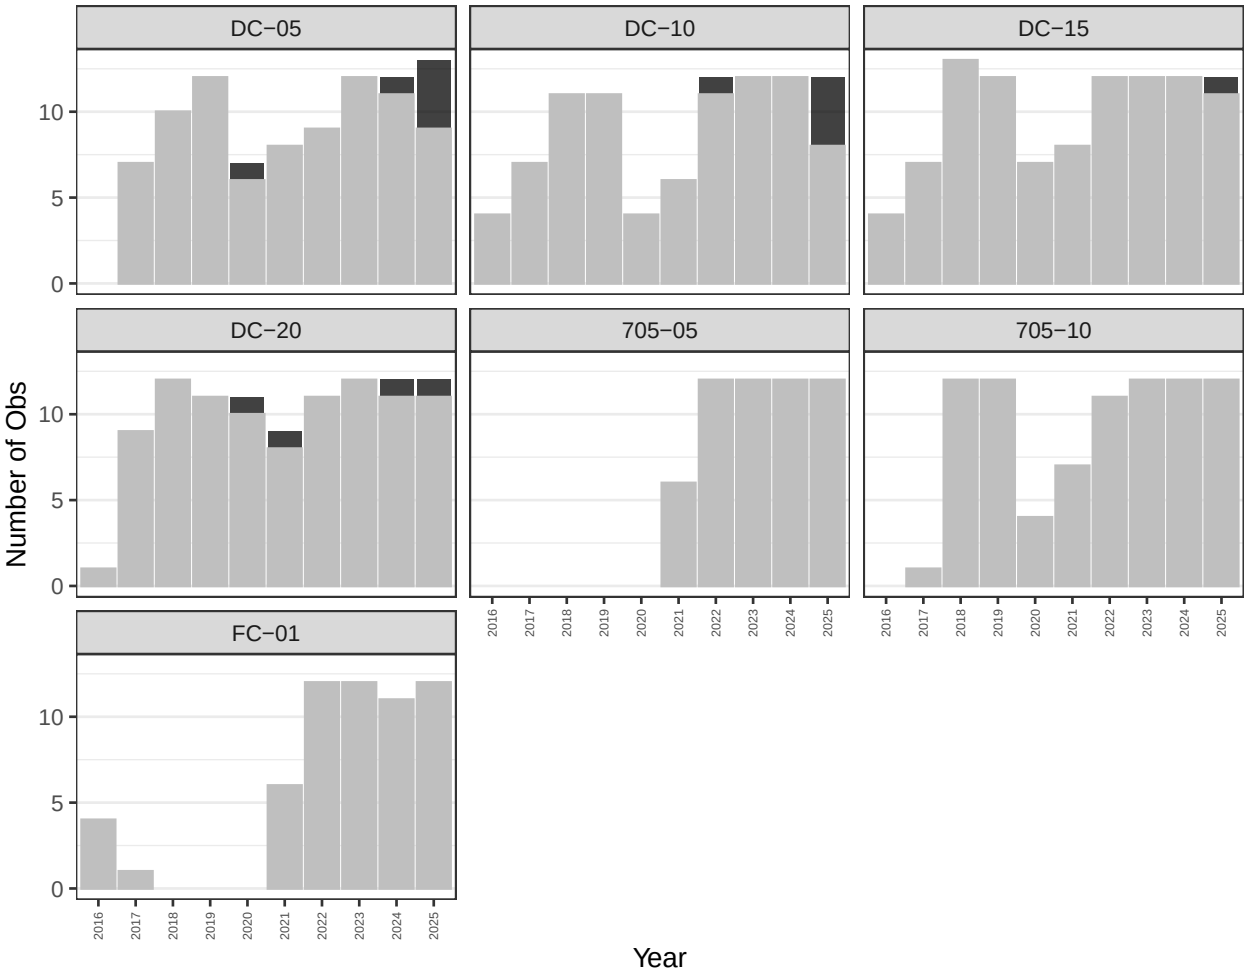
Final Summary Table

Variable	Nitrate-N
Watershed	Davidson Creek
Waterbody	Stream
Streams Removed	All Excluded
Data Transformation	N/A
Model Type	N/A
Benchmark	None
Significant BACI term	N/A

A-12.1.7 Nitrite-N

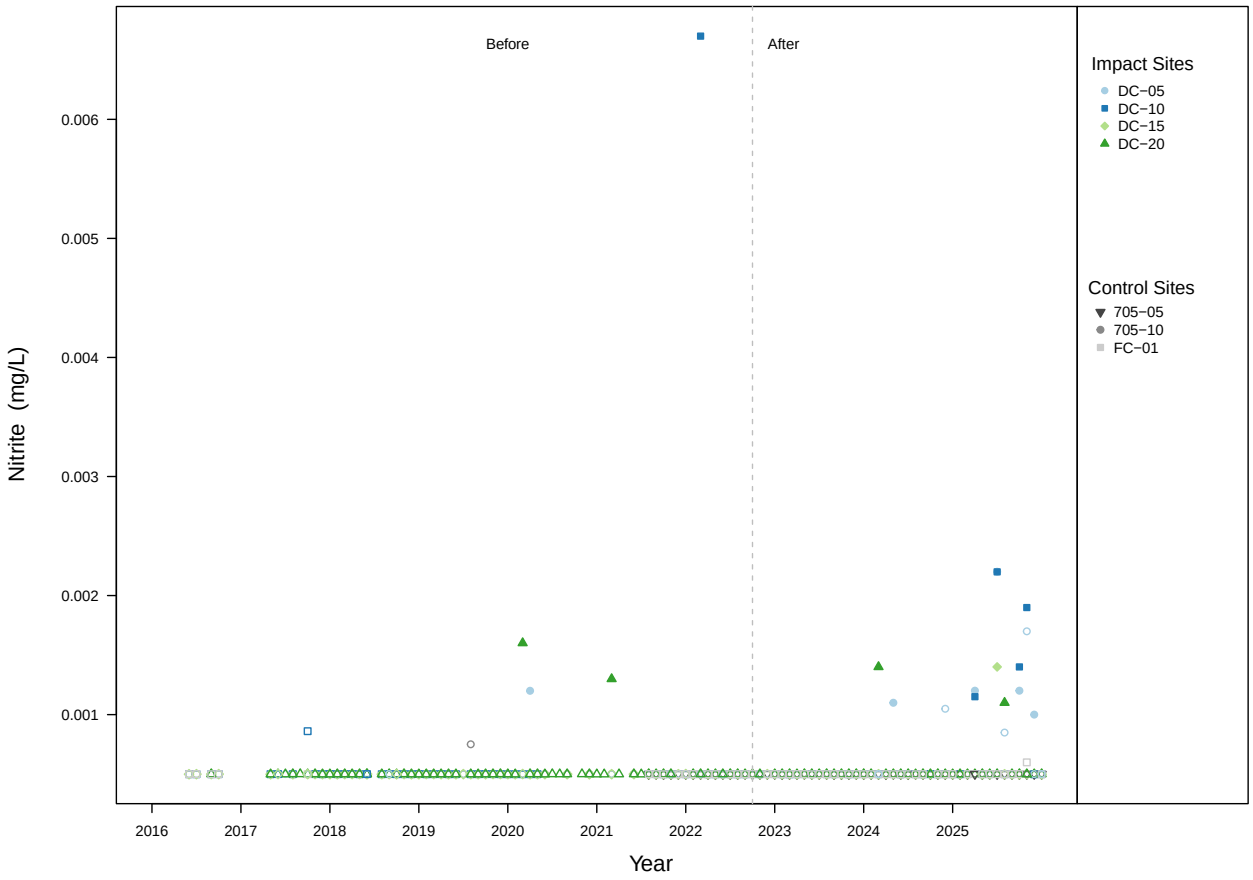
1 Davidson Creek

1.1 Censored Data The following charts indicate the number of measurements taken in each year from each stream that were below the detection limit (light gray) or above the detection limit (dark gray).



Conclusion:

Statistical analyses were not conducted due to censoring or availability of observations. Below is a summary figure of all observations in the dataset.



Note: Open symbols represent cases where the results were below the sample detection limit.

Final Summary Table

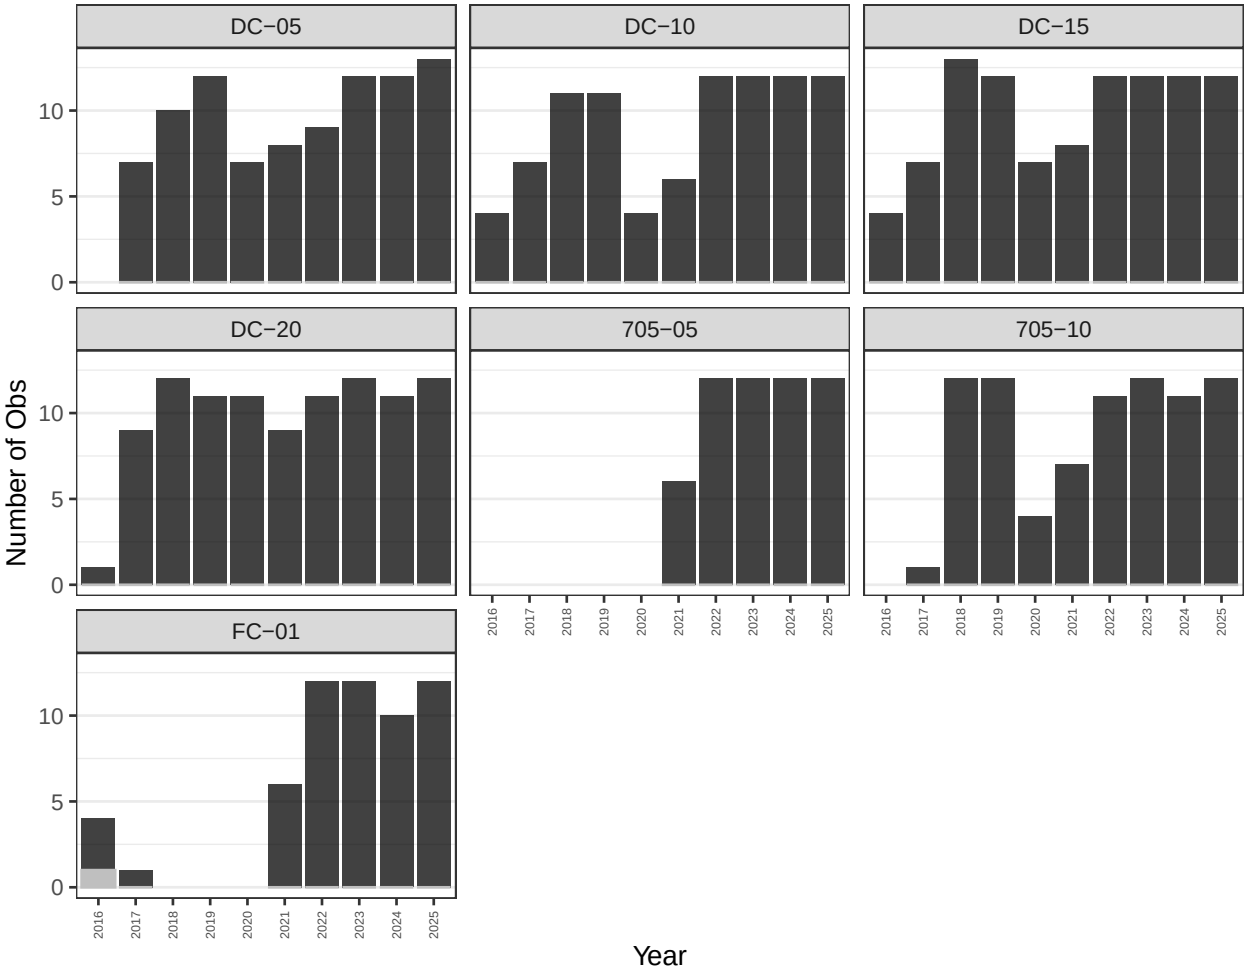
Variable	Nitrite
Watershed	Davidson Creek
Waterbody	Stream
Streams Removed	All Excluded
Data Transformation	N/A
Model Type	N/A
Benchmark	None
Significant BACI term	N/A

A-12.1.8 Total Phosphorus

1 Davidson Creek

1.1 Censored Data

The following charts indicate the number of measurements taken in each year from each stream that were below the detection limit (light gray) or above the detection limit (dark gray).



Observations at or below the analytical detection limit were considered censored. Data were excluded from the analysis if greater than 70% of observations from a site were censored or if greater than 50% of observations in a site's sampling year were censored. If more than 10% of observations from a site in a sampling year were censored, data were flagged to caution interpretation of results. The following observations were excluded:

None

1.2 Sample Sizes for Modelling

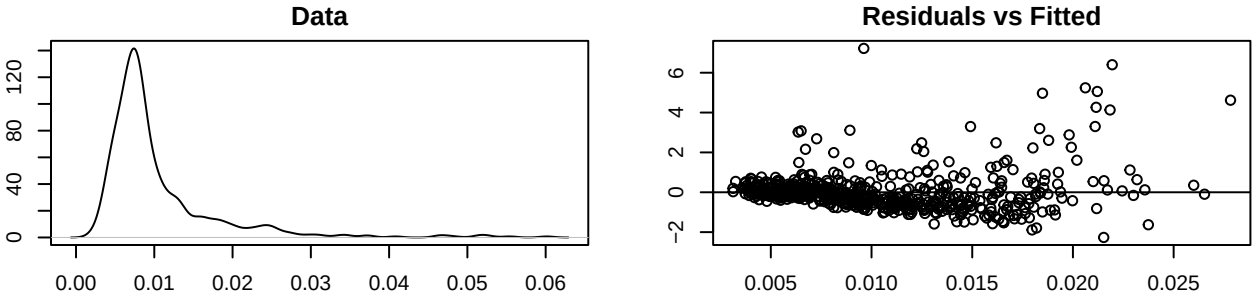
The remaining sample sizes per site and period are summarised in the table below.

Watershed	Site	Period	N	Median	% Censored
Davidson Creek	DC-05	before	51	0.0081	0
Davidson Creek	DC-05	after	39	0.0138	0
Davidson Creek	DC-10	before	52	0.0074	0
Davidson Creek	DC-10	after	39	0.0108	0
Davidson Creek	DC-15	before	60	0.0074	0
Davidson Creek	DC-15	after	39	0.0087	0
Davidson Creek	DC-20	before	62	0.0082	0
Davidson Creek	DC-20	after	37	0.0130	0
Creek 705 (Control)	705-05	before	15	0.0079	0
Creek 705 (Control)	705-05	after	39	0.0084	0
Creek 705 (Control)	705-10	before	45	0.0059	0
Creek 705 (Control)	705-10	after	37	0.0061	0
Fawnie Creek (Control)	FC-01	before	20	0.0043	5
Fawnie Creek (Control)	FC-01	after	37	0.0059	0

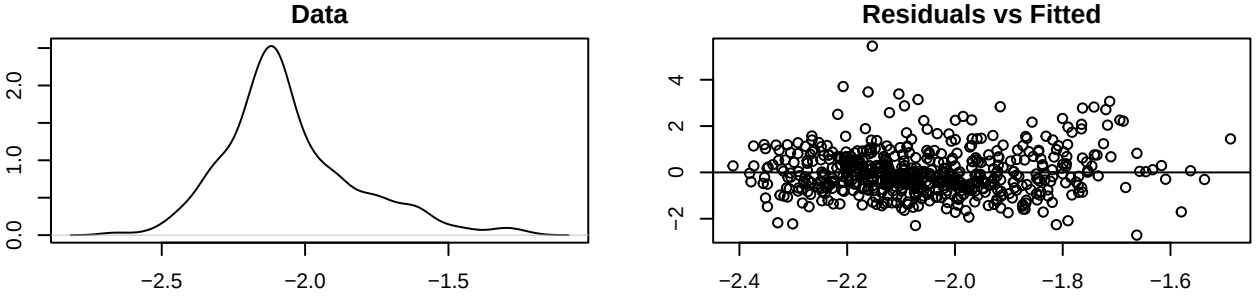
1.3 Initial Model Fit

Initially a model was fit to all sites to assess the need for transformations.

Natural Scale Model



Log−10 Transformed Model



Outliers

The following is a summary of outliers identified (if any) using preliminary regression models. All data points were plotted in the summary figures. The analysis needs to be interpreted with care and in conjunction with graphical displays if large outliers are present.

Outliers on natural scale:

Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Fawnie Creek (Control)	FC-01	2022	6	control	before	0.0527	0.0096	7.219	Y
Davidson Creek	DC-20	2024	3	impact	after	0.0602	0.0220	6.400	Y
Davidson Creek	DC-15	2023	5	impact	after	0.0519	0.0206	5.242	Y
Davidson Creek	DC-05	2024	3	impact	after	0.0514	0.0212	5.058	Y
Davidson Creek	DC-20	2018	5	impact	before	0.0482	0.0185	4.970	Y
Davidson Creek	DC-05	2024	5	impact	after	0.0554	0.0278	4.620	Y
Davidson Creek	DC-10	2023	5	impact	after	0.0466	0.0212	4.264	Y
Davidson Creek	DC-20	2024	4	impact	after	0.0465	0.0218	4.131	Y
Davidson Creek	DC-05	2024	4	impact	after	0.0408	0.0211	3.300	Y
Creek 705 (Control)	705-05	2024	3	control	after	0.0346	0.0149	3.298	Y
Davidson Creek	DC-05	2024	2	impact	after	0.0374	0.0183	3.196	Y
Davidson Creek	DC-20	2017	10	impact	before	0.0275	0.0089	3.112	Y
Davidson Creek	DC-15	2020	2	impact	before	0.0249	0.0065	3.082	Y
Davidson Creek	DC-15	2017	10	impact	before	0.0244	0.0064	3.022	Y

Outliers on log scale:

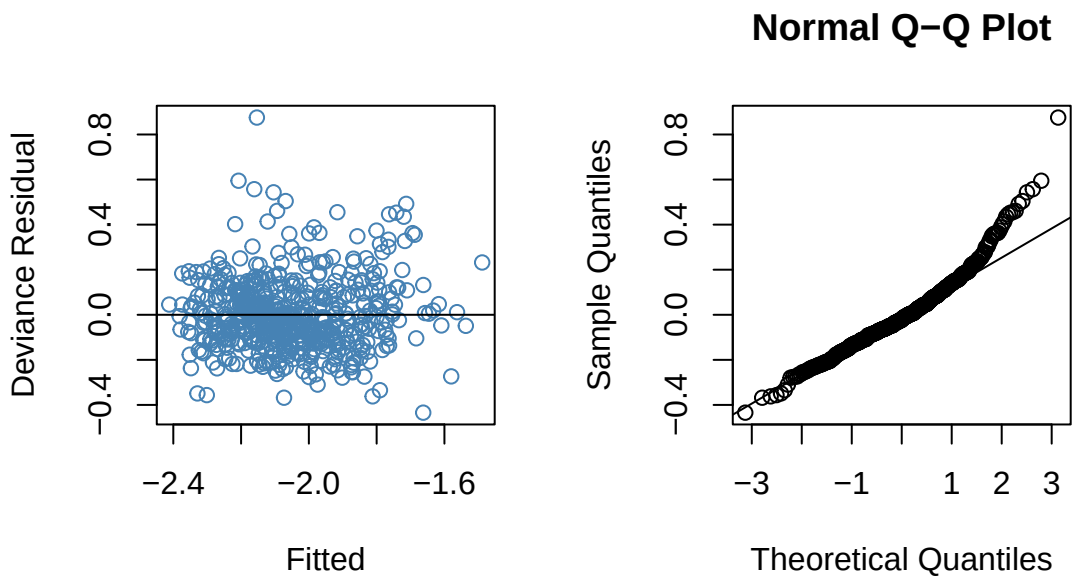
Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Fawnie Creek (Control)	FC-01	2022	6	control	before	-1.278	-2.153	5.454	Y
Davidson Creek	DC-15	2017	10	impact	before	-1.613	-2.207	3.707	Y
Davidson Creek	DC-15	2020	2	impact	before	-1.604	-2.161	3.473	Y
Davidson Creek	DC-20	2017	10	impact	before	-1.561	-2.104	3.387	Y
Creek 705 (Control)	705-10	2024	3	control	after	-1.564	-2.068	3.145	Y
Davidson Creek	DC-20	2024	3	impact	after	-1.221	-1.713	3.067	Y

Based on examination of the residuals, the log-10 transformed data were selected for analysis. No outliers were removed prior to analysis.

1.4 Before-After Control-Impact Linear Modeling

A models was fit to compare impact sites with control sites.

Plot of Standardized Residuals and Fitted Values



Results of the ANOVA test on the fixed effects of the model:

	Sum Sq.	Mean Sq.	NumDF	DenDF	F value	p	p adjusted
class	0.253552	0.253552	1	5.089	9.8485	0.0251	
period	0.001179	0.001179	1	86.872	0.0458	0.831	
class:period	0.705782	0.705782	1	551.312	27.4141	<0.001	1.12e-06

Results of the observed power calculation for the between-effect test on the fixed effects for repeated-measures ANOVA analysis at a significance level of 0.05:

Sample Size	Effect Size (f2)	Expected Power	Power Test
572	0.178	96%	Repeated-Measures ANOVA

Summary of BACI contrasts for relative difference between changes from the *before* to *after* in impact sites (DC-05, DC-10, DC-15, DC-20) and control sites (705-05, 705-10, FC-01), with p value adjusted for multiple comparisons:

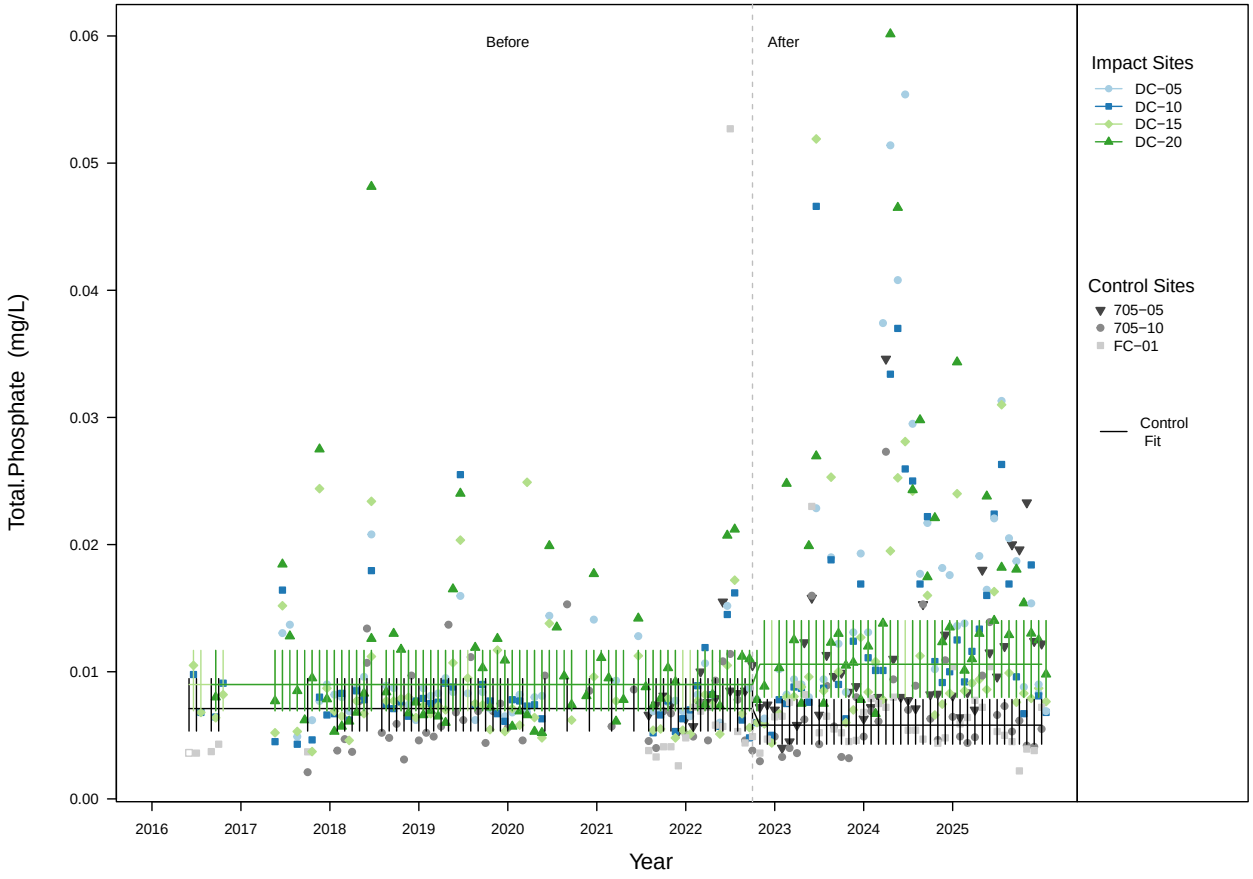
Impact vs.	Estimate	Significance
control sites	0.1588	significant

Conclusion:

The change in Total.Phosphate concentrations at the impact sites from *before* to *after* was significantly (*adjusted p* = 1.12×10^{-6}) different from the change at the control sites, according to the test on the BACI term (*class:period*).

1.5 Model Summary

The overall performance of the model is shown in the plot below. All the observations are plotted along with the model estimates. The model fitted values and 95% confidence intervals are indicated as lines and errors.



Note: Open symbols represent cases where the results were below the sample detection limit. Model fitted values are based on site class and period. Error bars indicate 95% confidence intervals. The positions of data along the x-axis are adjusted for legibility. Modelled log-transformed values were converted back to natural scale.

Final Summary Table

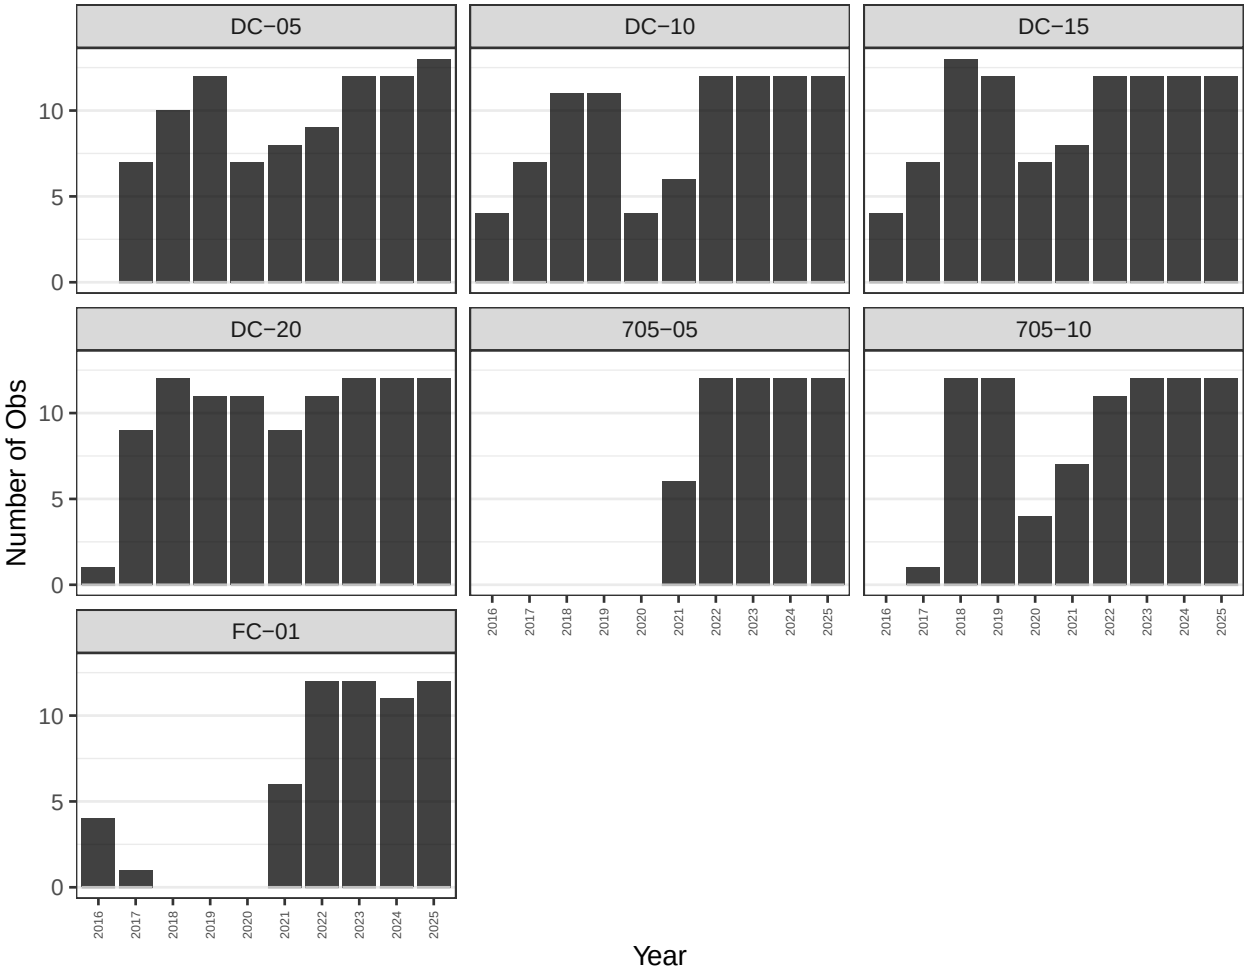
Variable	Total.Phosphate
Watershed	Davidson Creek
Waterbody	Stream
Streams Removed	None
Data Transformation	Log-10 transformed
Model Type	Linear Mixed Effects Regression
Is BACI significant	Yes

A-12.1.9 Total Aluminum

1 Davidson Creek

1.1 Censored Data

The following charts indicate the number of measurements taken in each year from each stream that were below the detection limit (light gray) or above the detection limit (dark gray).



Observations at or below the analytical detection limit were considered censored. Data were excluded from the analysis if greater than 70% of observations from a site were censored or if greater than 50% of observations in a site's sampling year were censored. If more than 10% of observations from a site in a sampling year were censored, data were flagged to caution interpretation of results. The following observations were excluded:

None

1.2 Sample Sizes for Modelling

The remaining sample sizes per site and period are summarised in the table below.

Watershed	Site	Period	N	Median	% Censored
Davidson Creek	DC-05	before	51	0.0491	0
Davidson Creek	DC-05	after	39	0.2015	0

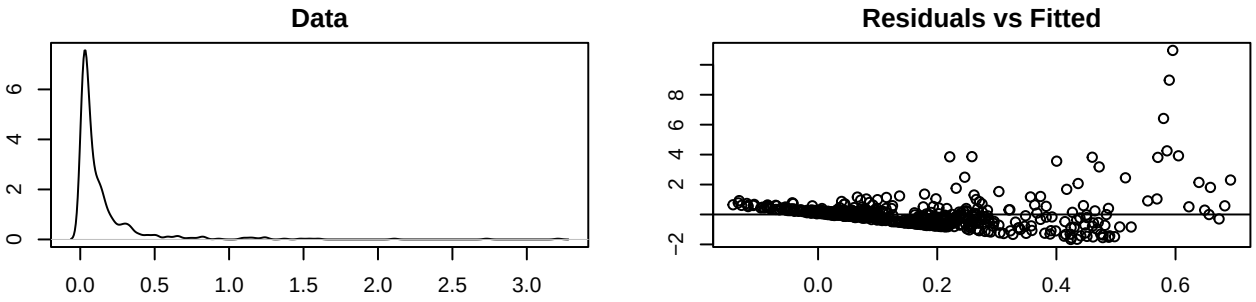
Fawnie Creek (Control)	FC-01	before	20	0.0237	0
Fawnie Creek (Control)	FC-01	after	38	0.0172	0

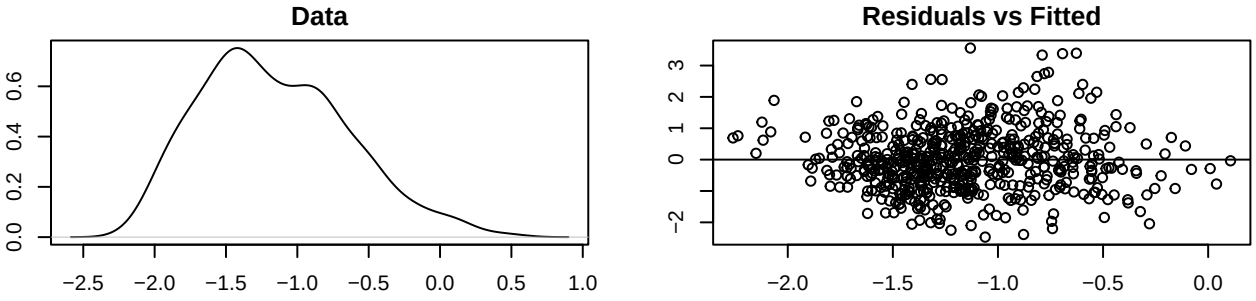
1.3 Initial Model Fit

Initially a model was fit to all sites to assess the need for transformations.

Natural Scale Model



Log−10 Transformed Model



Outliers

The following is a summary of outliers identified (if any) using preliminary regression models. All data points were plotted in the summary figures. The analysis needs to be interpreted with care and in conjunction with graphical displays if large outliers are present.

Outliers on natural scale:

Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Davidson Creek	DC-20	2024	4	impact	after	3.210	0.5953	10.960	Y
Davidson Creek	DC-05	2024	3	impact	after	2.730	0.5895	8.973	Y
Davidson Creek	DC-20	2024	3	impact	after	2.110	0.5799	6.414	Y
Davidson Creek	DC-10	2024	4	impact	after	1.600	0.5857	4.252	Y
Davidson Creek	DC-05	2024	4	impact	after	1.540	0.6049	3.920	Y
Davidson Creek	DC-20	2018	5	impact	before	1.180	0.2582	3.864	Y
Fawnie Creek (Control)	FC-01	2022	6	control	before	1.140	0.2210	3.852	Y
Davidson Creek	DC-05	2024	2	impact	after	1.373	0.4602	3.825	Y
Davidson Creek	DC-10	2024	3	impact	after	1.480	0.5703	3.813	Y
Davidson Creek	DC-15	2025	6	impact	after	1.250	0.4004	3.561	Y
Davidson Creek	DC-20	2024	12	impact	after	1.230	0.4718	3.178	Y

Outliers on log scale:

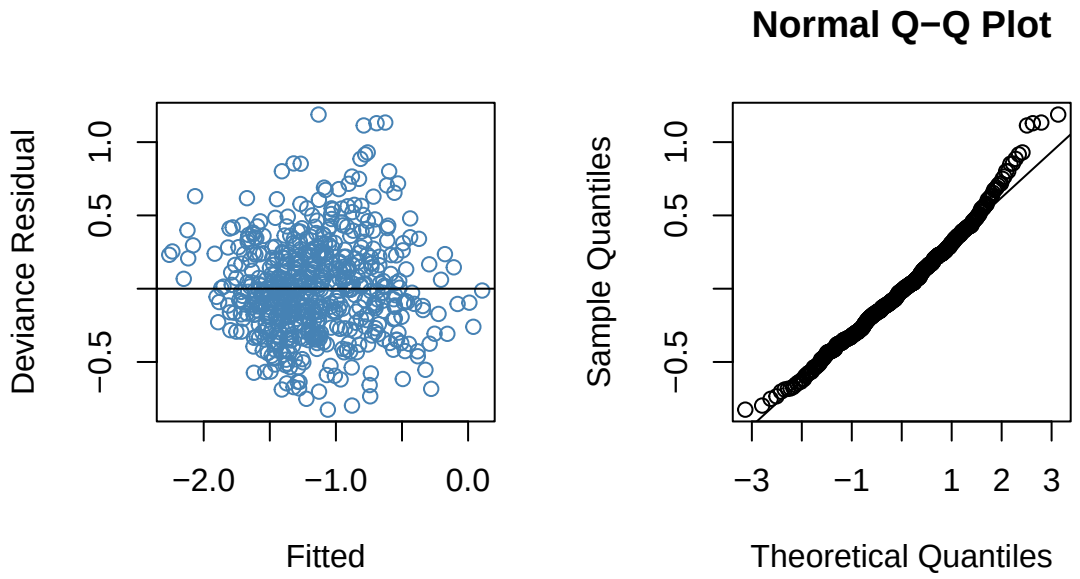
Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Fawnie Creek (Control)	FC-01	2022	6	control	before	0.0569	-1.1312	3.557	Y
Davidson Creek	DC-20	2024	4	impact	after	0.5065	-0.6270	3.393	Y
Davidson Creek	DC-05	2024	3	impact	after	0.4362	-0.6927	3.379	Y
Davidson Creek	DC-20	2024	3	impact	after	0.3243	-0.7895	3.334	Y

Based on examination of the residuals, the log-10 transformed data were selected for analysis. No outliers were removed prior to analysis.

1.4 Before-After Control-Impact Linear Modeling

A models was fit to compare impact sites with control sites.

Plot of Standardized Residuals and Fitted Values



Results of the ANOVA test on the fixed effects of the model:

	Sum Sq.	Mean Sq.	NumDF	DenDF	F value	p	p adjusted
class	0.172	0.172	1	5.067	1.541	0.269	
period	2.561	2.561	1	272.749	22.951	<0.001	
class:period	8.828	8.828	1	551.093	79.108	<0.001	1.21e-16

Results of the observed power calculation for the between-effect test on the fixed effects for repeated-measures ANOVA analysis at a significance level of 0.05:

Sample Size	Effect Size (f2)	Expected Power	Power Test
575	0.1878	98%	Repeated-Measures ANOVA

Summary of BACI contrasts for relative difference between changes from the *before* to *after* in impact sites (DC-05, DC-10, DC-15, DC-20) and control sites (705-05, 705-10, FC-01), with p value adjusted for multiple comparisons:

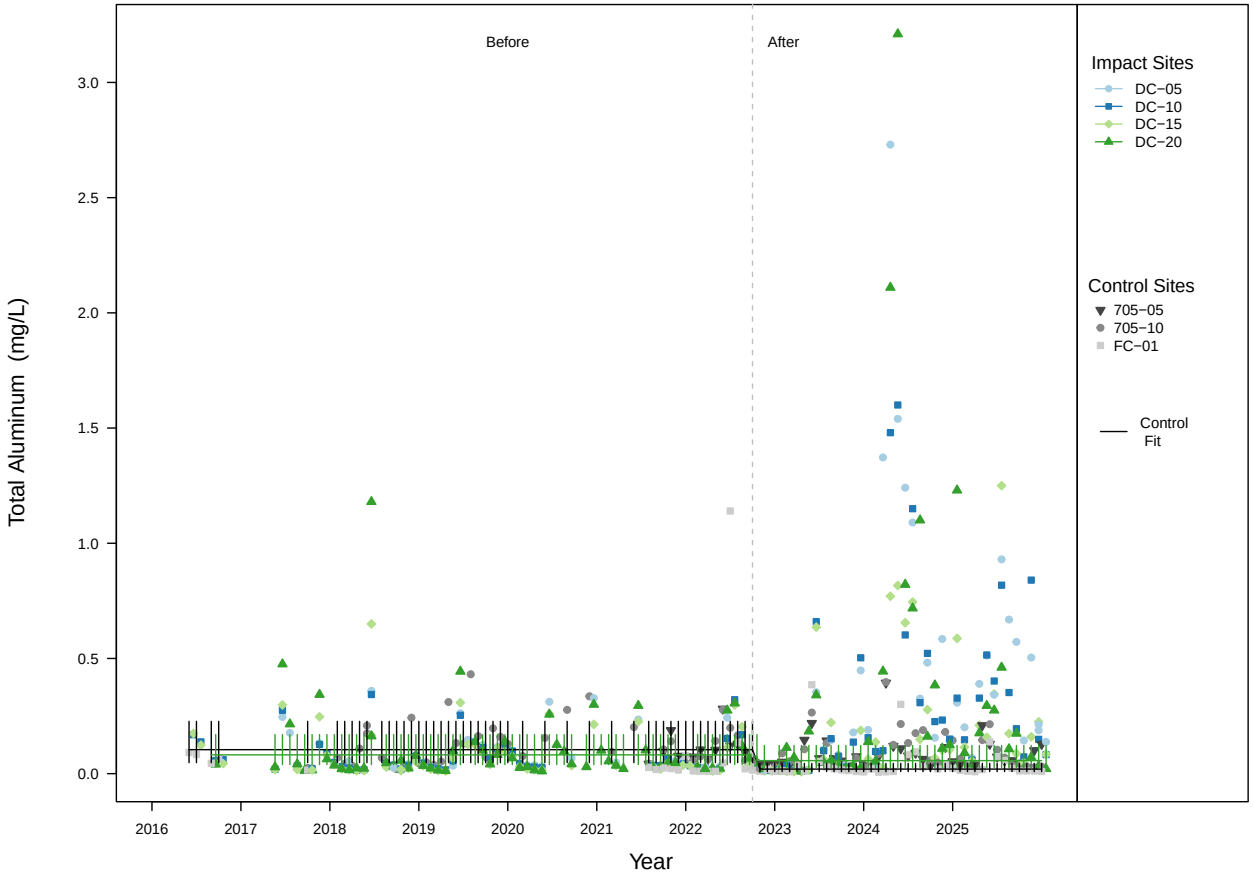
Impact vs.	Estimate	Significance
control sites	0.5602	significant

Conclusion:

The change in Total Aluminum concentrations at the impact sites from *before* to *after* was significantly (*adjusted p* = 1.21×10^{-16}) different from the change at the control sites, according to the test on the BACI term (*class:period*).

1.5 Model Summary

The overall performance of the model is shown in the plot below. All the observations are plotted along with the model estimates. The model fitted values and 95% confidence intervals are indicated as lines and errors.



Note: Model fitted values are based on site class and period. Error bars indicate 95% confidence intervals. The positions of data along the x-axis are adjusted for legibility. Modelled log-transformed values were converted back to natural scale.

Final Summary Table

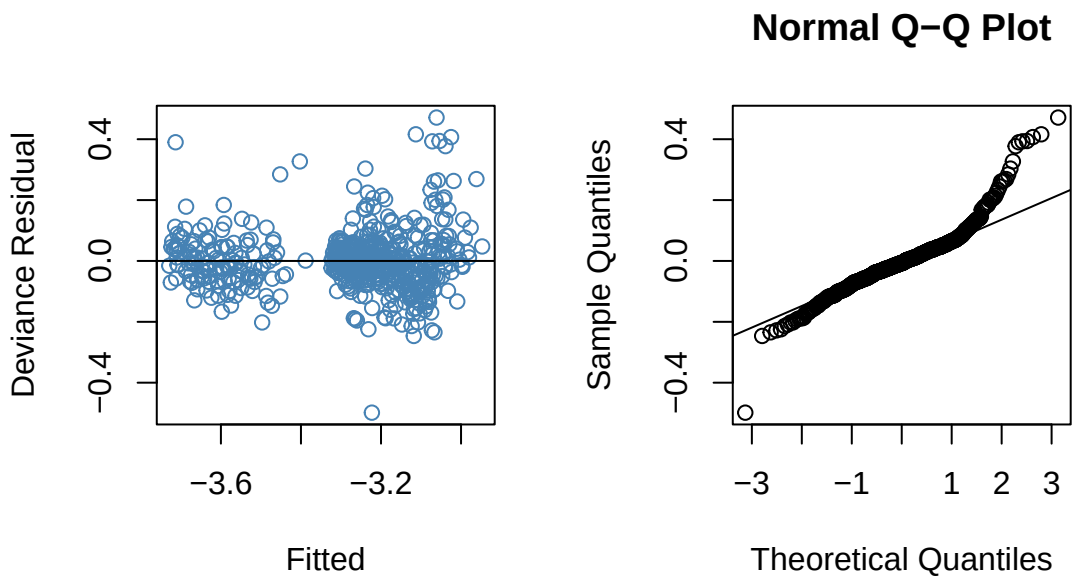
Davidson Creek	DC-05	2024	3	impact	after	-2.662	-3.039	3.780	Y
Creek 705 (Control)	705-05	2025	8	control	after	-3.076	-3.403	3.276	Y
Davidson Creek	DC-20	2017	10	impact	before	-2.936	-3.239	3.040	Y

Based on examination of the residuals, the log-10 transformed data were selected for analysis. No outliers were removed prior to analysis.

1.4 Before-After Control-Impact Linear Modeling

A models was fit to compare impact sites with control sites.

Plot of Standardized Residuals and Fitted Values



Results of the ANOVA test on the fixed effects of the model:

	Sum Sq.	Mean Sq.	NumDF	DenDF	F value	p	p adjusted
class	0.04585	0.04585	1	5.007	4.602	0.0847	
period	0.08754	0.08754	1	33.521	8.786	0.00555	
class:period	0.39296	0.39296	1	554.176	39.439	<0.001	4.33e-09

Results of the observed power calculation for the between-effect test on the fixed effects for repeated-measures ANOVA analysis at a significance level of 0.05:

Sample Size	Effect Size (f2)	Expected Power	Power Test
575	0.4316	100%	Repeated-Measures ANOVA

Summary of BACI contrasts for relative difference between changes from the *before* to *after* in impact sites (DC-05, DC-10, DC-15, DC-20) and control sites (705-05, 705-10, FC-01), with p value adjusted for multiple comparisons:

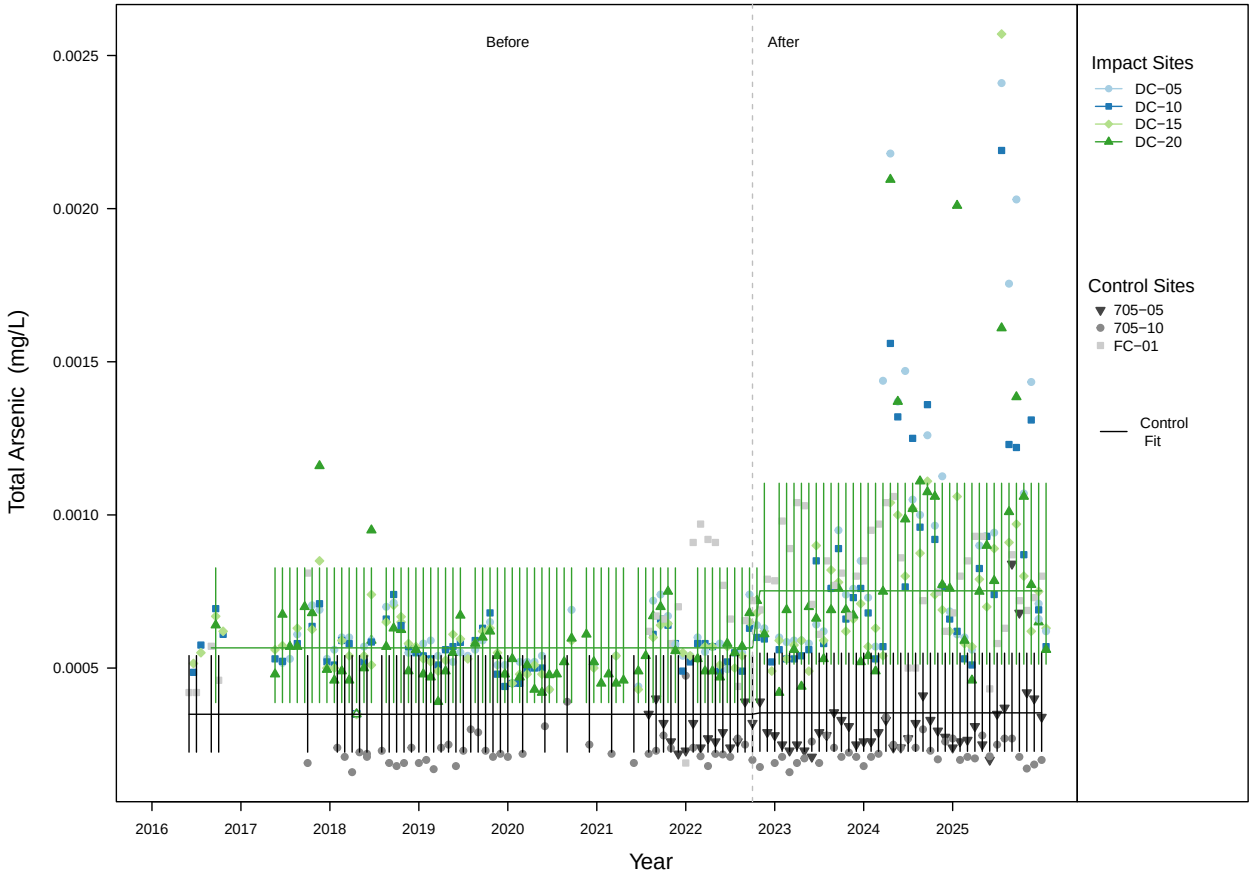
Impact vs.	Estimate	Significance
control sites	0.1179	significant

Conclusion:

The change in Total Arsenic concentrations at the impact sites from *before* to *after* was significantly (*adjusted p =* 4.33×10^{-9}) different from the change at the control sites, according to the test on the BACI term (*class:period*).

1.5 Model Summary

The overall performance of the model is shown in the plot below. All the observations are plotted along with the model estimates. The model fitted values and 95% confidence intervals are indicated as lines and errors.



Note: Open symbols represent cases where the results were below the sample detection limit. Model fitted values are based on site class and period. Error bars indicate 95% confidence intervals. The positions of data along the x-axis are adjusted for legibility. Modelled log-transformed values were converted back to natural scale.

Final Summary Table

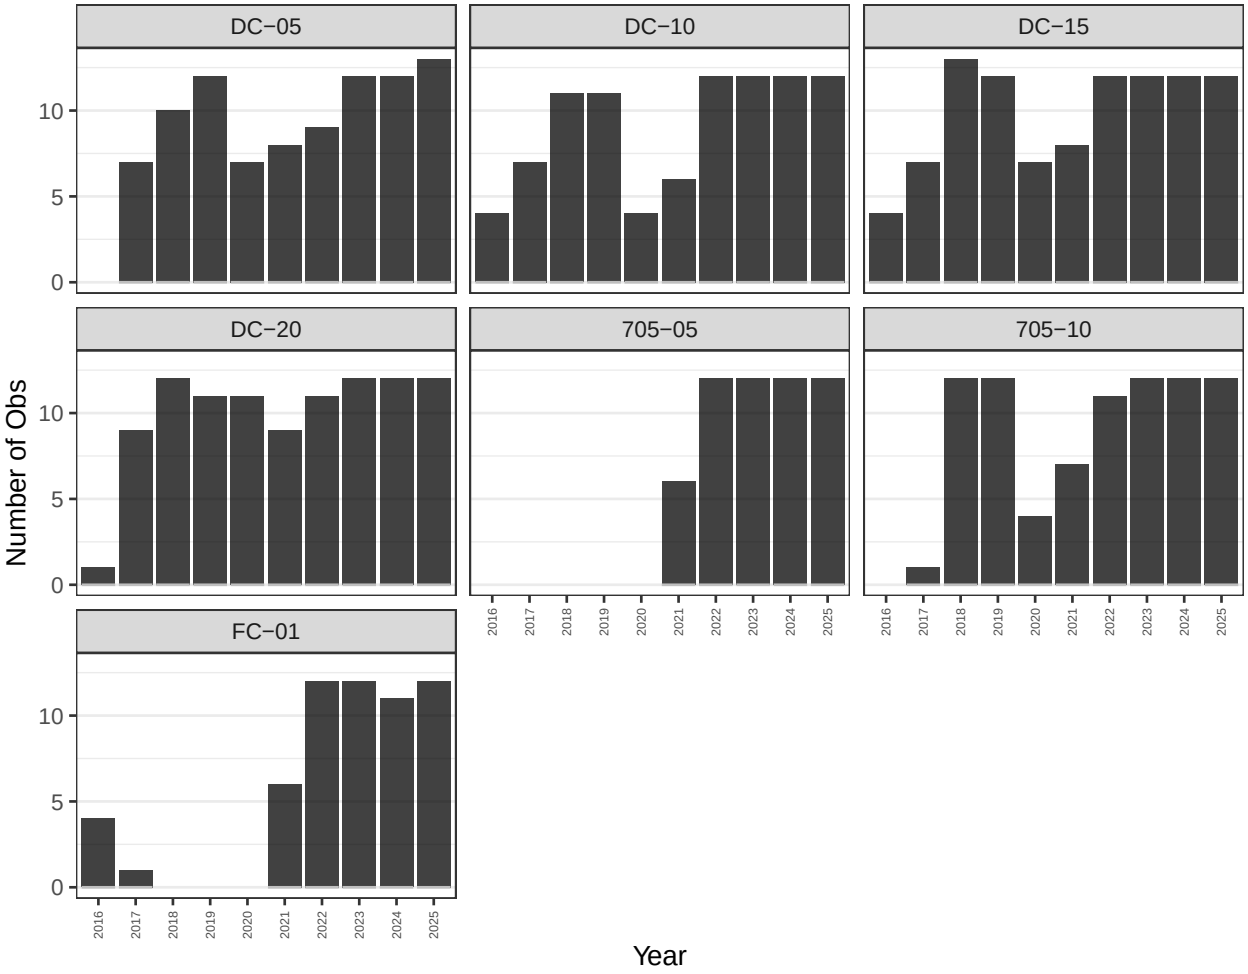
Variable	Total Arsenic
Watershed	Davidson Creek
Waterbody	Stream
Streams Removed	None
Data Transformation	Log-10 transformed
Model Type	Linear Mixed Effects Regression
Is BACI significant	Yes

A-12.1.12 Total Barium

1 Davidson Creek

1.1 Censored Data

The following charts indicate the number of measurements taken in each year from each stream that were below the detection limit (light gray) or above the detection limit (dark gray).



Observations at or below the analytical detection limit were considered censored. Data were excluded from the analysis if greater than 70% of observations from a site were censored or if greater than 50% of observations in a site's sampling year were censored. If more than 10% of observations from a site in a sampling year were censored, data were flagged to caution interpretation of results. The following observations were excluded:

None

1.2 Sample Sizes for Modelling

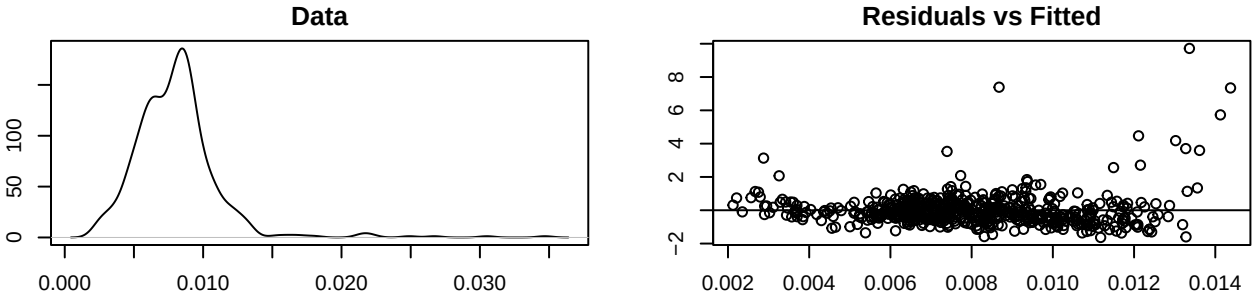
The remaining sample sizes per site and period are summarised in the table below.

Watershed	Site	Period	N	Median	% Censored
Davidson Creek	DC-05	before	51	0.0063	0
Davidson Creek	DC-05	after	39	0.0096	0
Davidson Creek	DC-10	before	52	0.0064	0
Davidson Creek	DC-10	after	39	0.0096	0
Davidson Creek	DC-15	before	60	0.0074	0
Davidson Creek	DC-15	after	39	0.0099	0
Davidson Creek	DC-20	before	62	0.0079	0
Davidson Creek	DC-20	after	38	0.0098	0
Creek 705 (Control)	705-05	before	15	0.0060	0
Creek 705 (Control)	705-05	after	39	0.0071	0
Creek 705 (Control)	705-10	before	45	0.0088	0
Creek 705 (Control)	705-10	after	38	0.0088	0
Fawnie Creek (Control)	FC-01	before	20	0.0041	0
Fawnie Creek (Control)	FC-01	after	38	0.0039	0

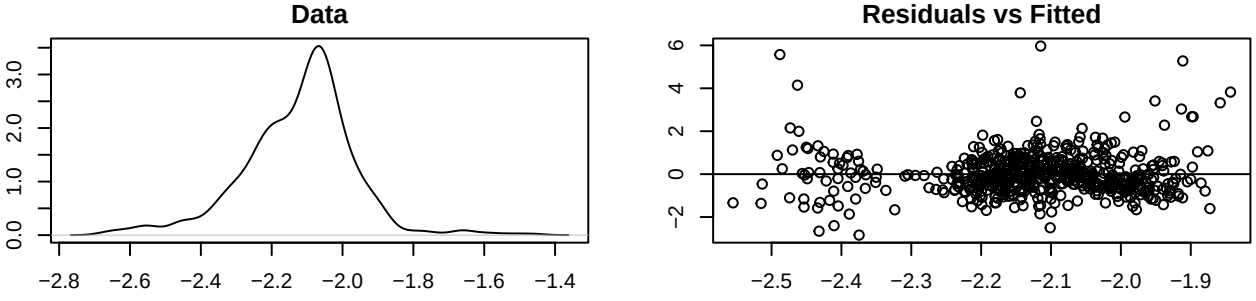
1.3 Initial Model Fit

Initially a model was fit to all sites to assess the need for transformations.

Natural Scale Model



Log−10 Transformed Model



Outliers

The following is a summary of outliers identified (if any) using preliminary regression models. All data points were plotted in the summary figures. The analysis needs to be interpreted with care and in conjunction with graphical displays if large outliers are present.

Outliers on natural scale:

Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Davidson Creek	DC-05	2024	3	impact	after	0.0347	0.0134	9.719	Y
Davidson Creek	DC-05	2020	4	impact	before	0.0249	0.0087	7.390	Y
Davidson Creek	DC-20	2024	4	impact	after	0.0305	0.0144	7.345	Y
Davidson Creek	DC-20	2024	3	impact	after	0.0267	0.0141	5.727	Y
Davidson Creek	DC-05	2024	2	impact	after	0.0219	0.0121	4.468	Y
Davidson Creek	DC-10	2024	3	impact	after	0.0222	0.0130	4.180	Y
Davidson Creek	DC-10	2024	4	impact	after	0.0214	0.0133	3.702	Y
Davidson Creek	DC-05	2024	4	impact	after	0.0215	0.0136	3.593	Y
Davidson Creek	DC-20	2018	5	impact	before	0.0152	0.0074	3.532	Y
Fawnie Creek (Control)	FC-01	2022	6	control	before	0.0098	0.0029	3.131	Y

Outliers on log scale:

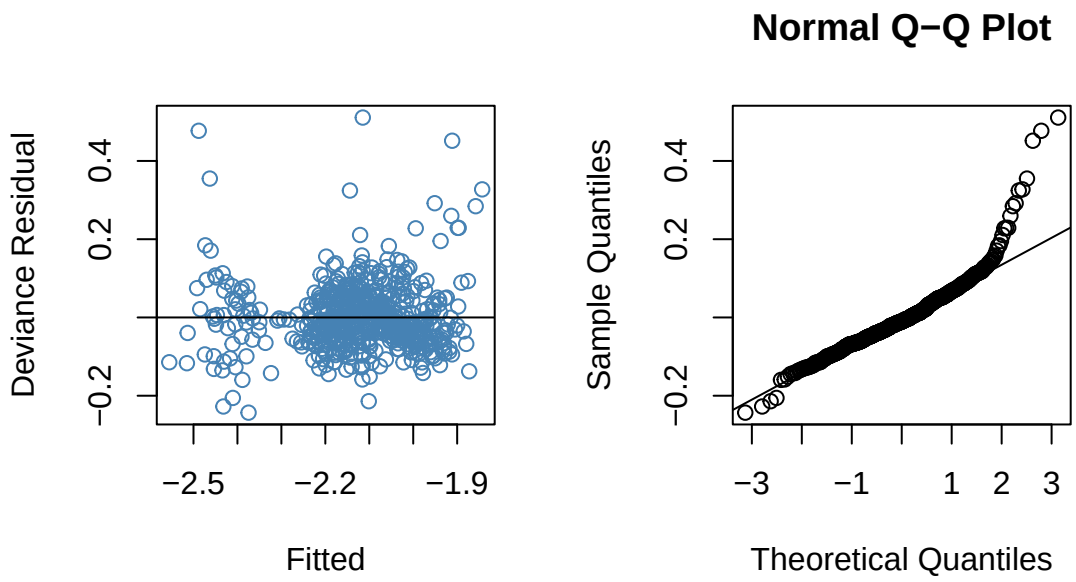
Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Davidson Creek	DC-05	2020	4	impact	before	-1.604	-2.115	5.968	Y
Fawnie Creek (Control)	FC-01	2022	6	control	before	-2.011	-2.488	5.572	Y
Davidson Creek	DC-05	2024	3	impact	after	-1.460	-1.911	5.276	Y
Fawnie Creek (Control)	FC-01	2021	12	control	before	-2.108	-2.463	4.146	Y
Davidson Creek	DC-20	2024	4	impact	after	-1.516	-1.843	3.824	Y
Davidson Creek	DC-20	2018	5	impact	before	-1.820	-2.144	3.789	Y
Davidson Creek	DC-05	2024	2	impact	after	-1.659	-1.951	3.410	Y
Davidson Creek	DC-20	2024	3	impact	after	-1.573	-1.858	3.322	Y
Davidson Creek	DC-10	2024	3	impact	after	-1.654	-1.913	3.033	Y

Based on examination of the residuals, the log-10 transformed data were selected for analysis. No outliers were removed prior to analysis.

1.4 Before-After Control-Impact Linear Modeling

A models was fit to compare impact sites with control sites.

Plot of Standardized Residuals and Fitted Values



Results of the ANOVA test on the fixed effects of the model:

	Sum Sq.	Mean Sq.	NumDF	DenDF	F value	p	p adjusted
class	0.01668	0.01668	1	5.01	2.275	0.192	
period	0.24148	0.24148	1	31.15	32.944	<0.001	
class:period	0.59672	0.59672	1	554.43	81.409	<0.001	6.44e-17

Results of the observed power calculation for the between-effect test on the fixed effects for repeated-measures ANOVA analysis at a significance level of 0.05:

Sample Size	Effect Size (f2)	Expected Power	Power Test
575	0.3395	100%	Repeated-Measures ANOVA

Summary of BACI contrasts for relative difference between changes from the *before* to *after* in impact sites (DC-05, DC-10, DC-15, DC-20) and control sites (705-05, 705-10, FC-01), with p value adjusted for multiple comparisons:

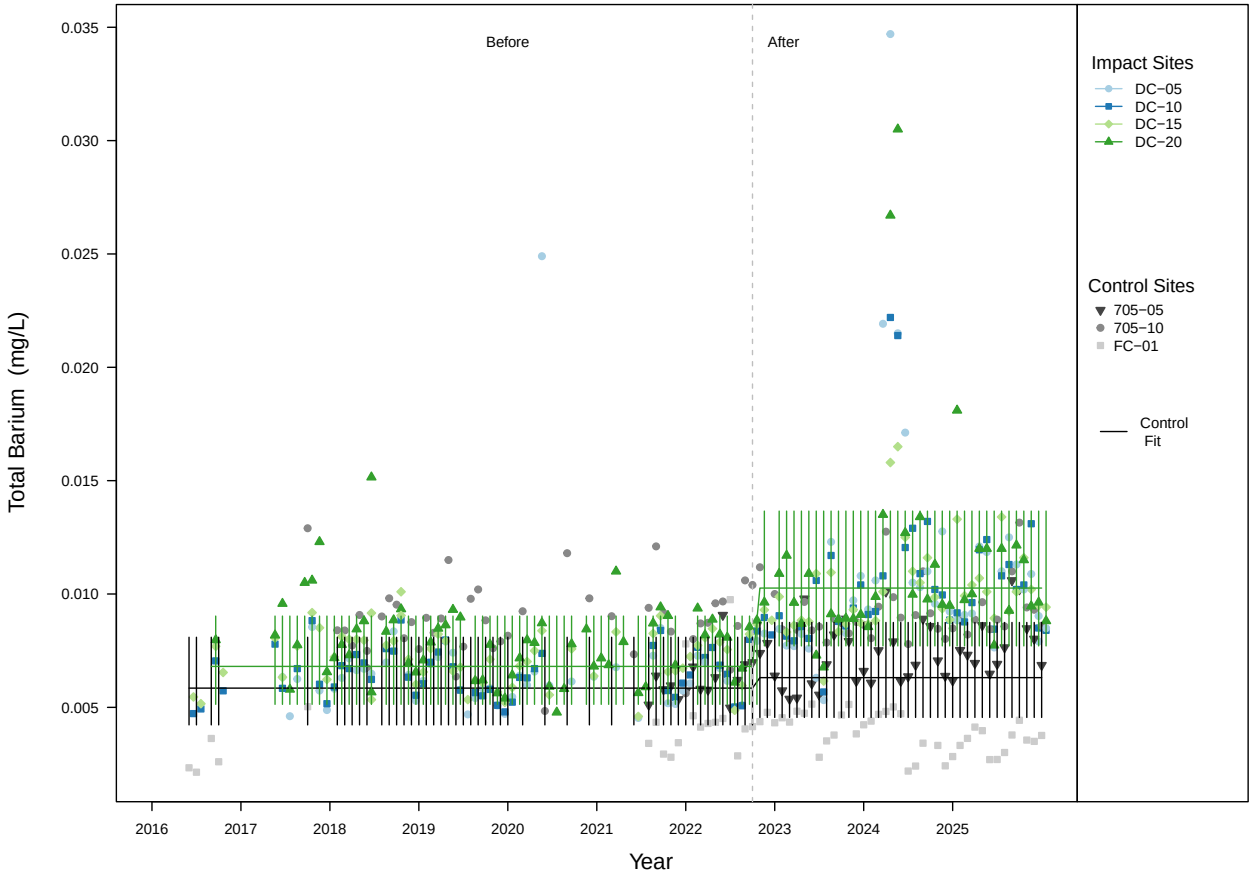
Impact vs.	Estimate	Significance
control sites	0.1452	significant

Conclusion:

The change in Total Barium concentrations at the impact sites from *before* to *after* was significantly (*adjusted p =* 6.44×10^{-17}) different from the change at the control sites, according to the test on the BACI term (*class:period*).

1.5 Model Summary

The overall performance of the model is shown in the plot below. All the observations are plotted along with the model estimates. The model fitted values and 95% confidence intervals are indicated as lines and errors.



Note: Model fitted values are based on site class and period. Error bars indicate 95% confidence intervals. The positions of data along the x-axis are adjusted for legibility. Modelled log-transformed values were converted back to natural scale.

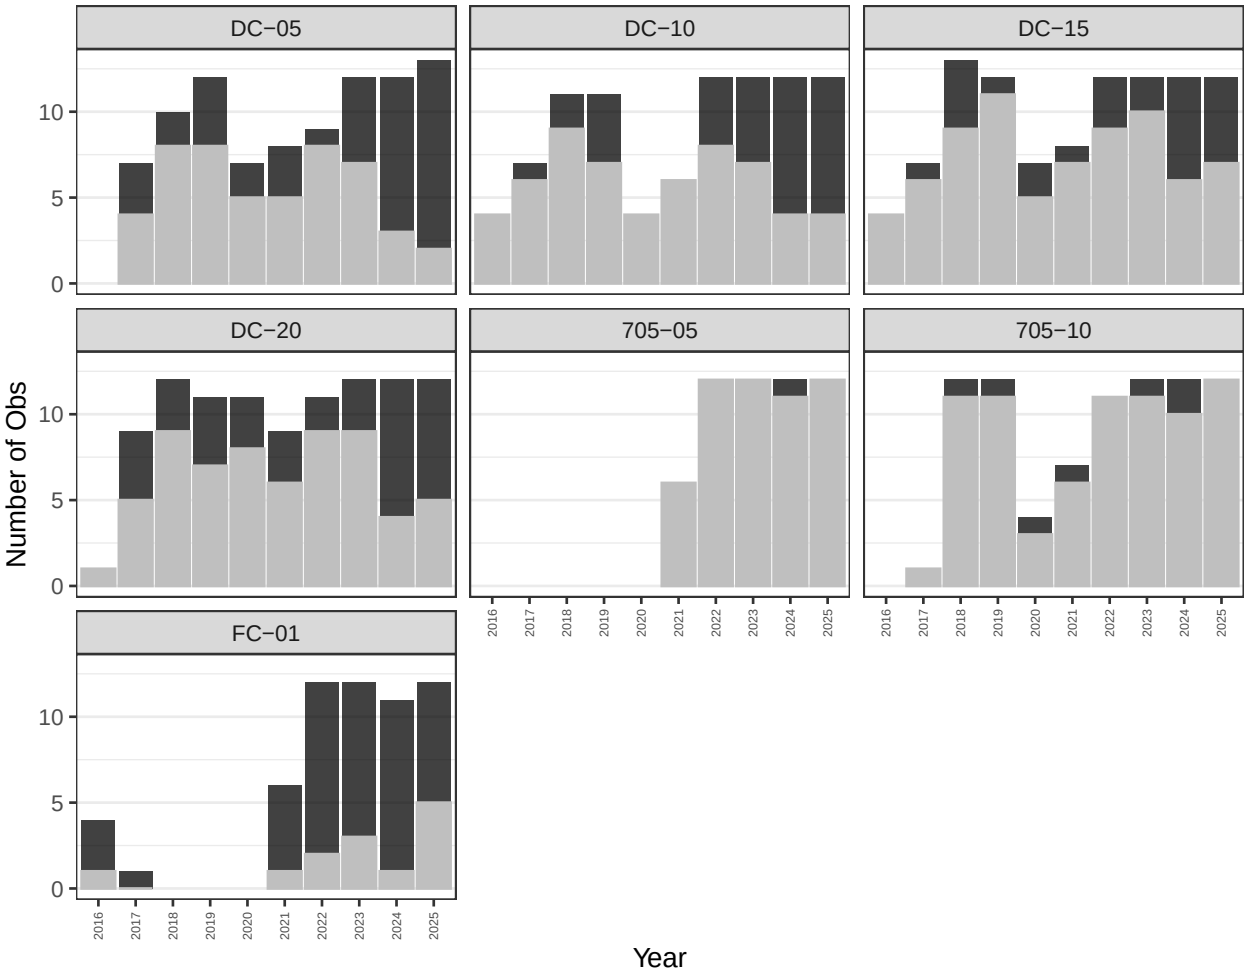
Final Summary Table

Variable	Total Barium
Watershed	Davidson Creek
Waterbody	Stream
Streams Removed	None
Data Transformation	Log-10 transformed
Model Type	Linear Mixed Effects Regression
Is BACI significant	Yes

A-12.1.13 Total Cadmium

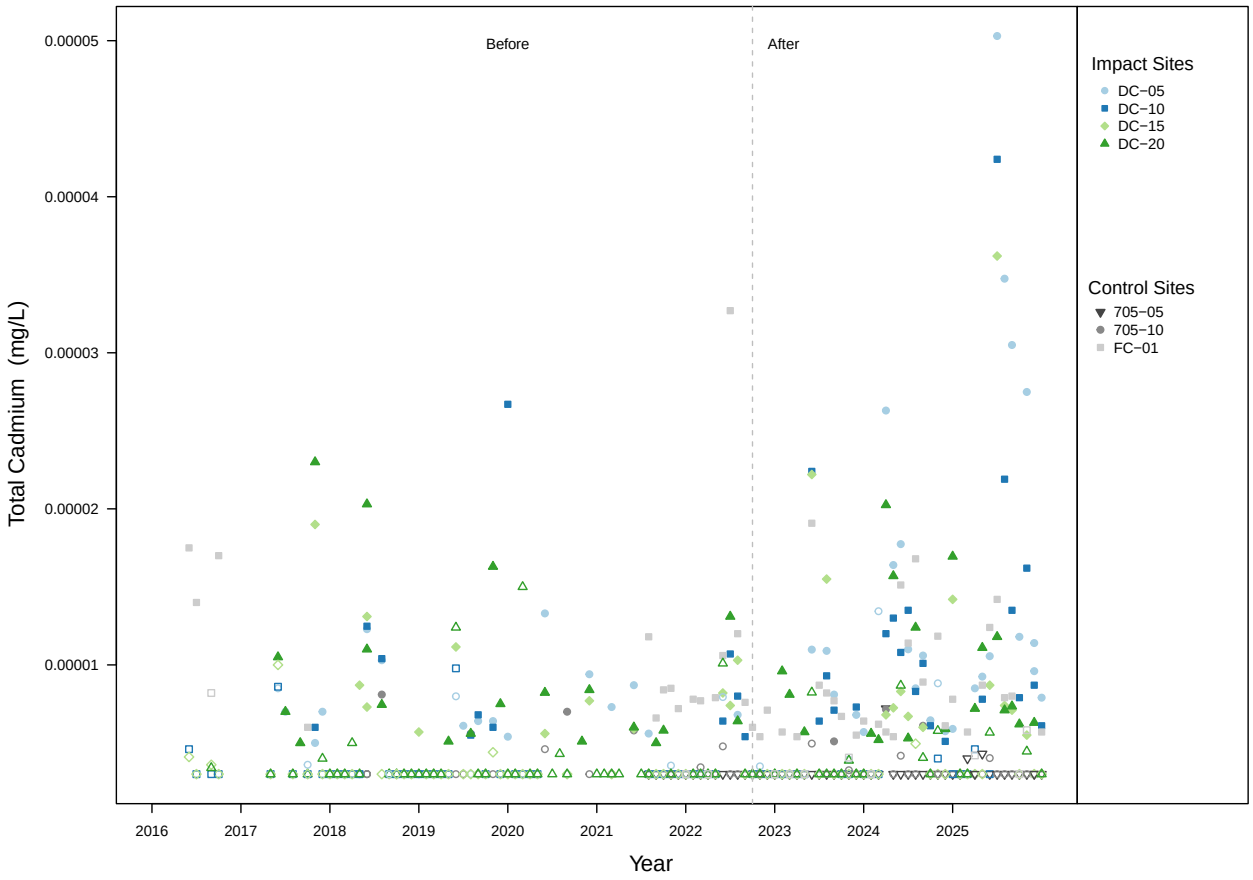
1 Davidson Creek

1.1 Censored Data The following charts indicate the number of measurements taken in each year from each stream that were below the detection limit (light gray) or above the detection limit (dark gray).



Conclusion:

Statistical analyses were not conducted due to censoring or availability of observations. Below is a summary figure of all observations in the dataset.



Note: Open symbols represent cases where the results were below the sample detection limit.

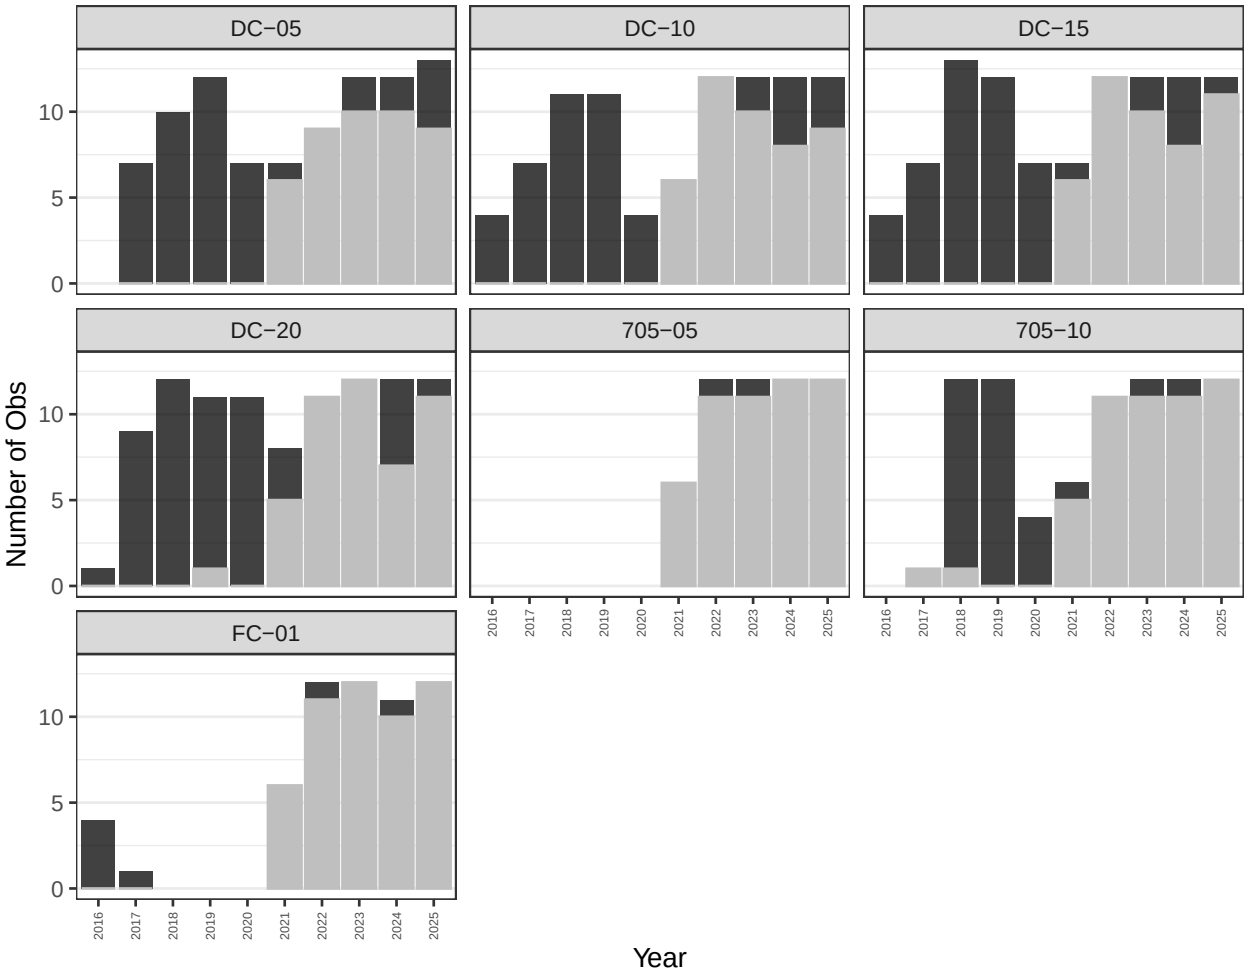
Final Summary Table

Variable	Total Cadmium
Watershed	Davidson Creek
Waterbody	Stream
Streams Removed	All Excluded
Data Transformation	N/A
Model Type	N/A
Benchmark	None
Significant BACI term	N/A

A-12.1.14 Total Chromium

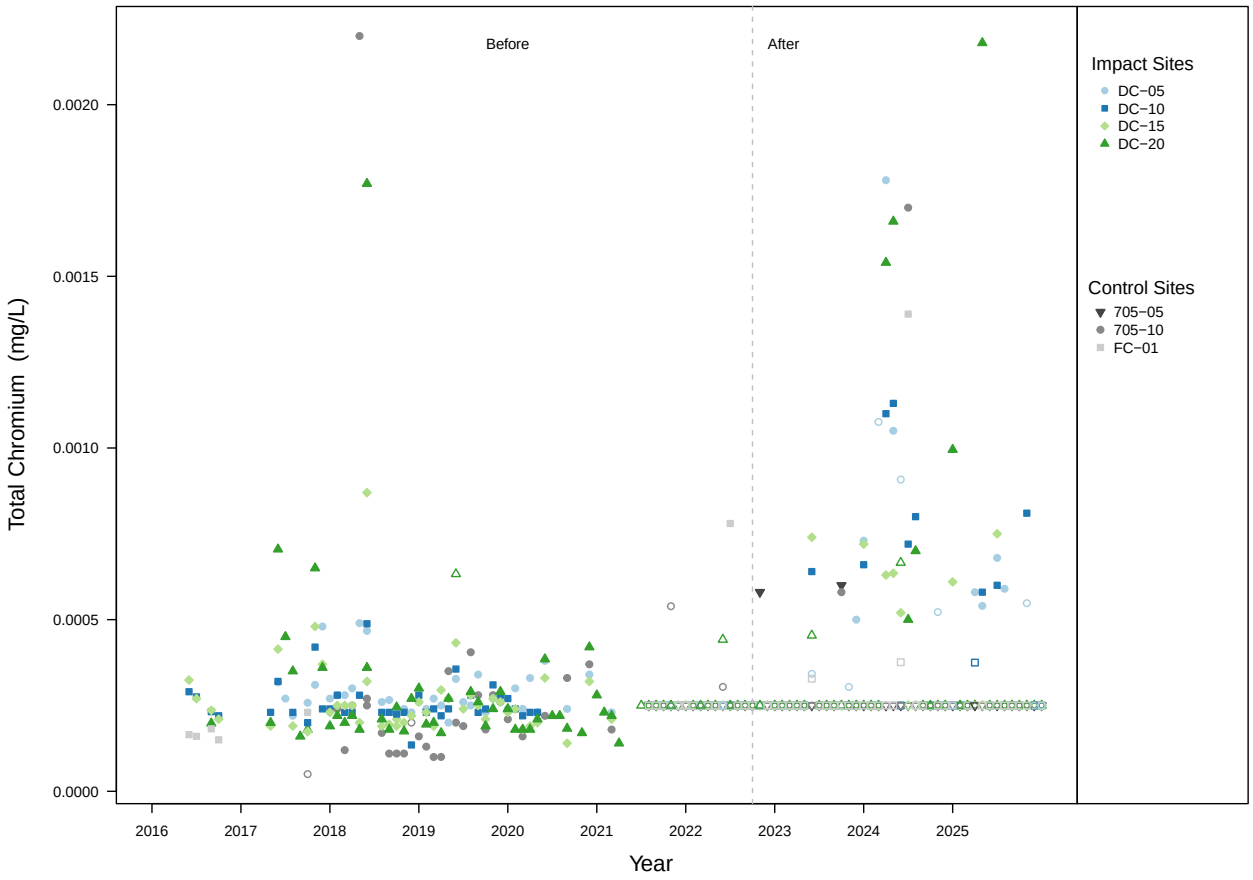
1 Davidson Creek

1.1 Censored Data The following charts indicate the number of measurements taken in each year from each stream that were below the detection limit (light gray) or above the detection limit (dark gray).



Conclusion:

Statistical analyses were not conducted due to censoring or availability of observations. Below is a summary figure of all observations in the dataset.



Note: Open symbols represent cases where the results were below the sample detection limit.

Final Summary Table

Variable	Total Chromium
Watershed	Davidson Creek

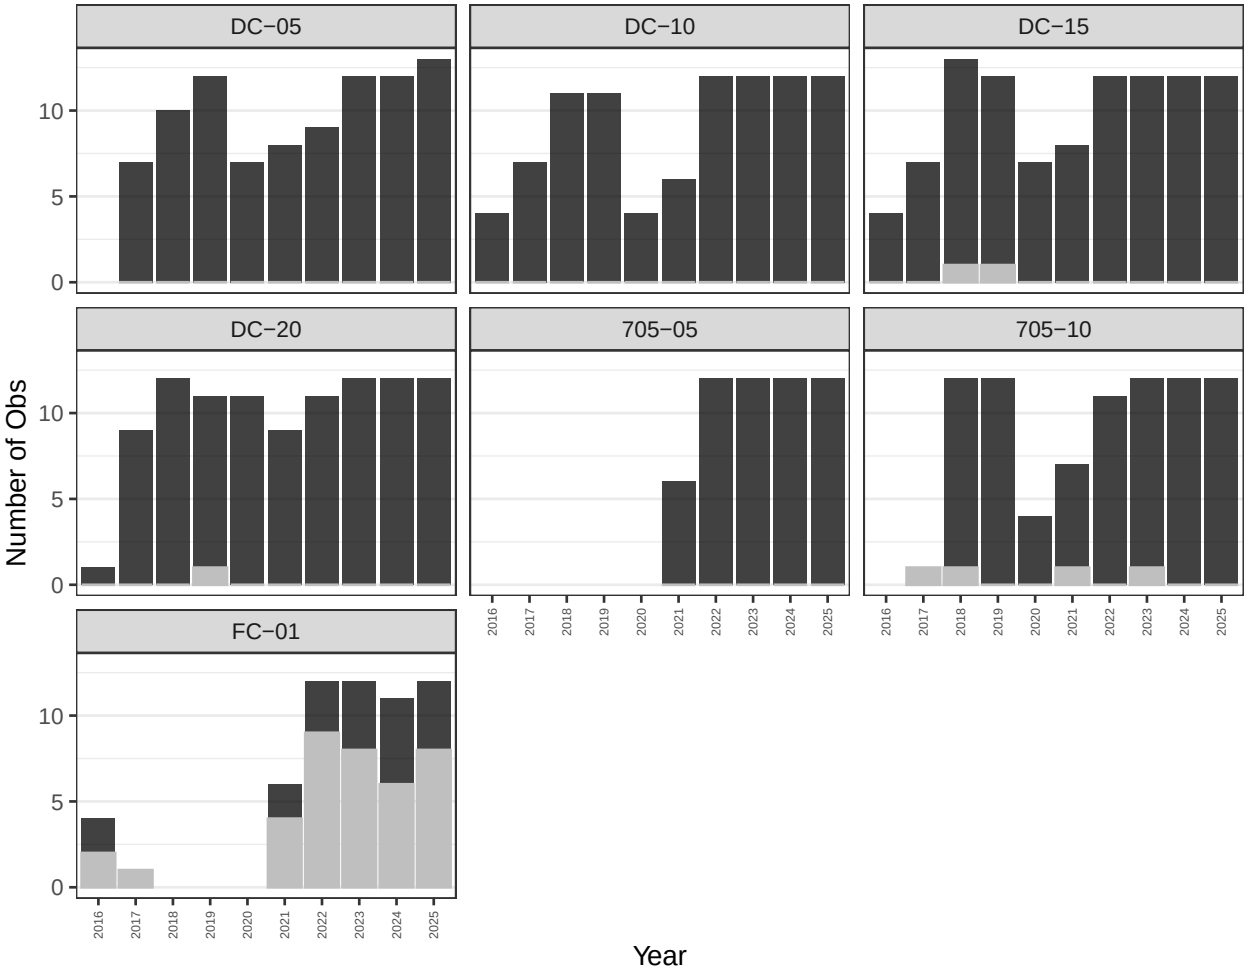
A-12.1.17 Total Iron

1 Davidson Creek

1.1 Censored Data

The following charts indicate the number of measurements taken in each year from each stream that were below the detection limit (light gray) or above the detection limit (dark gray).



Observations at or below the analytical detection limit were considered censored. Data were excluded from the analysis if greater than 70% of observations from a site were censored or if greater than 50% of observations in a site's sampling year were censored. If more than 10% of observations from a site in a sampling year were censored, data were flagged to caution interpretation of results. The following observations were excluded:

Watershed	Site	Year	Class	Period	#Obs Removed
Creek 705 (Control)	705-10	2017	control	before	1
Fawnie Creek (Control)	FC-01	2017	control	before	1
Fawnie Creek (Control)	FC-01	2021	control	before	6
Fawnie Creek (Control)	FC-01	2022	control	before	12
Fawnie Creek (Control)	FC-01	2022	control	after	12
Fawnie Creek (Control)	FC-01	2023	control	after	12
Fawnie Creek (Control)	FC-01	2024	control	after	11

(Continued on Next Page...)

(continued)

Watershed	Site	Year	Class	Period	#Obs Removed
Fawnie Creek (Control)	FC-01	2025	control	after	12

1.2 Sample Sizes for Modelling

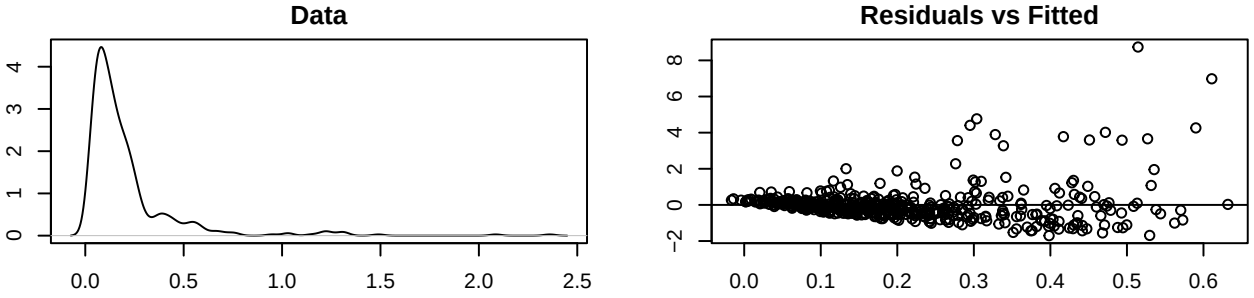
The remaining sample sizes per site and period are summarised in the table below.

Watershed	Site	Period	N	Median	% Censored
Davidson Creek	DC-05	before	51	0.0910	0.000
Davidson Creek	DC-05	after	39	0.2058	0.000
Davidson Creek	DC-10	before	52	0.0760	0.000
Davidson Creek	DC-10	after	39	0.1700	0.000
Davidson Creek	DC-15	before	60	0.0645	3.333
Davidson Creek	DC-15	after	39	0.1050	0.000
Davidson Creek	DC-20	before	62	0.1470	1.613
Davidson Creek	DC-20	after	38	0.3922	0.000
Creek 705 (Control)	705-05	before	15	0.2100	0.000
Creek 705 (Control)	705-05	after	39	0.2110	0.000
Creek 705 (Control)	705-10	before	28	0.1090	3.571
Fawnie Creek (Control)	FC-01	before	4	0.0335	50.000

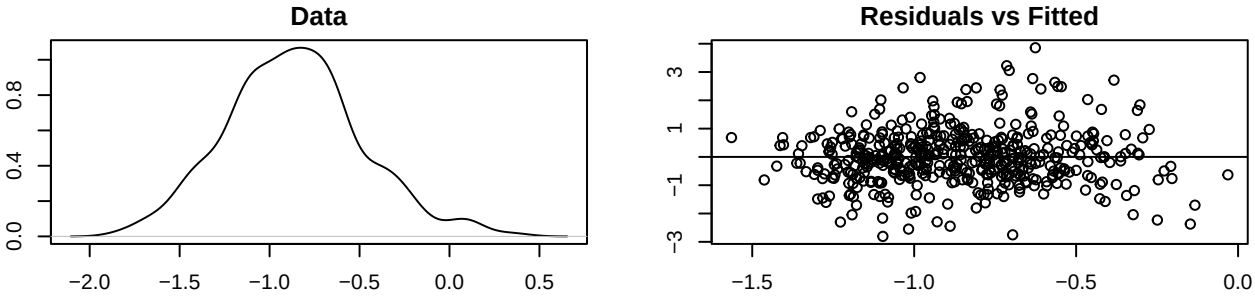
1.3 Initial Model Fit

Initially a model was fit to all sites to assess the need for transformations.

Natural Scale Model



Log−10 Transformed Model



Outliers

The following is a summary of outliers identified (if any) using preliminary regression models. All data points were plotted in the summary figures. The analysis needs to be interpreted with care and in conjunction with graphical displays if large outliers are present.

Outliers on natural scale:

Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Davidson Creek	DC-05	2024	3	impact	after	2.360	0.5145	8.741	Y
Davidson Creek	DC-20	2024	3	impact	after	2.085	0.6108	6.982	Y
Creek 705 (Control)	705-05	2025	9	control	after	1.310	0.3038	4.765	Y
Davidson Creek	DC-20	2018	5	impact	before	1.225	0.2951	4.404	Y
Davidson Creek	DC-20	2024	4	impact	after	1.490	0.5900	4.262	Y
Davidson Creek	DC-10	2024	3	impact	after	1.320	0.4719	4.017	Y
Creek 705 (Control)	705-05	2025	8	control	after	1.150	0.3280	3.893	Y
Davidson Creek	DC-05	2024	2	impact	after	1.215	0.4170	3.777	Y
Davidson Creek	DC-20	2024	12	impact	after	1.300	0.5270	3.661	Y
Davidson Creek	DC-10	2024	4	impact	after	1.210	0.4511	3.594	Y
Davidson Creek	DC-05	2024	4	impact	after	1.250	0.4937	3.582	Y
Davidson Creek	DC-20	2017	10	impact	before	1.030	0.2785	3.559	Y
Creek 705 (Control)	705-05	2025	10	control	after	1.030	0.3386	3.274	Y

Outliers on log scale:

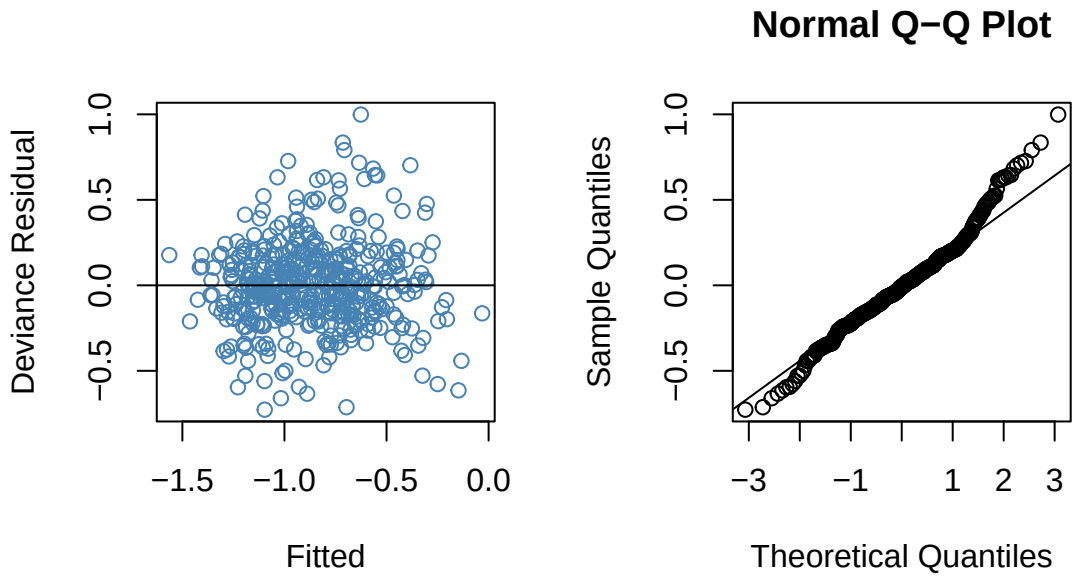
Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Davidson Creek	DC-05	2024	3	impact	after	0.3729	-0.6259	3.857	Y
Davidson Creek	DC-10	2024	3	impact	after	0.1206	-0.7142	3.224	Y
Davidson Creek	DC-05	2024	2	impact	after	0.0844	-0.7065	3.054	Y

Based on examination of the residuals, the log-10 transformed data were selected for analysis. No outliers were removed prior to analysis.

1.4 Before-After Control-Impact Linear Modeling

A models was fit to compare impact sites with control sites.

Plot of Standardized Residuals and Fitted Values



Results of the ANOVA test on the fixed effects of the model:

	Sum Sq.	Mean Sq.	NumDF	DenDF	F value	p	p adjusted
class	0.02704	0.02704	1	5.085	0.4033	0.5530	
period	0.28560	0.28560	1	166.628	4.2586	0.0406	
class:period	0.34288	0.34288	1	441.134	5.1127	0.0242	0.0341

Results of the observed power calculation for the between-effect test on the fixed effects for repeated-measures ANOVA analysis at a significance level of 0.05:

Sample Size	Effect Size (f2)	Expected Power	Power Test
466	0.0345	8%	Repeated-Measures ANOVA

Summary of BACI contrasts for relative difference between changes from the *before* to *after* in impact sites (DC-05, DC-10, DC-15, DC-20) and control sites (705-05, 705-10, FC-01), with p value adjusted for multiple comparisons:

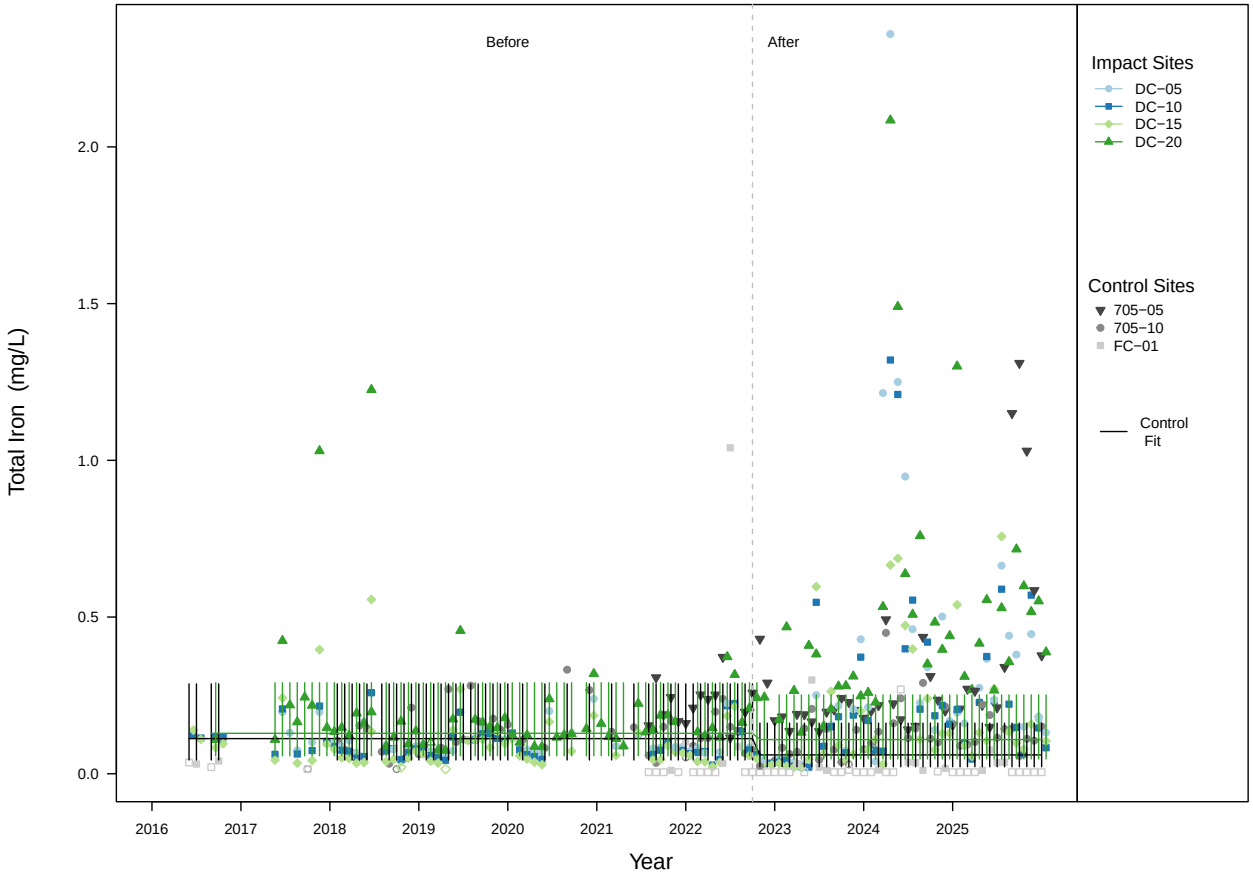
Impact vs.	Estimate	Significance
control sites	0.1972	significant

Conclusion:

The change in Total Iron concentrations at the impact sites from *before* to *after* was significantly (*adjusted p =* 0.0341) different from the change at the control sites, according to the test on the BACI term (*class:period*).

1.5 Model Summary

The overall performance of the model is shown in the plot below. All the observations are plotted along with the model estimates. The model fitted values and 95% confidence intervals are indicated as lines and errors.



Note: Open symbols represent cases where the results were below the sample detection limit. Model fitted values are based on site class and period. Error bars indicate 95% confidence intervals. The positions of data along the x-axis are adjusted for legibility. Modelled log-transformed values were converted back to natural scale.

class:period	3.042278	3.042278	1	553.257	39.9380	<0.001	4.33e-09

Results of the observed power calculation for the between-effect test on the fixed effects for repeated-measures ANOVA analysis at a significance level of 0.05:

Sample Size	Effect Size (f2)	Expected Power	Power Test
575	0.1649	93%	Repeated-Measures ANOVA

Summary of BACI contrasts for relative difference between changes from the *before* to *after* in impact sites (DC-05, DC-10, DC-15, DC-20) and control sites (705-05, 705-10, FC-01), with p value adjusted for multiple comparisons:

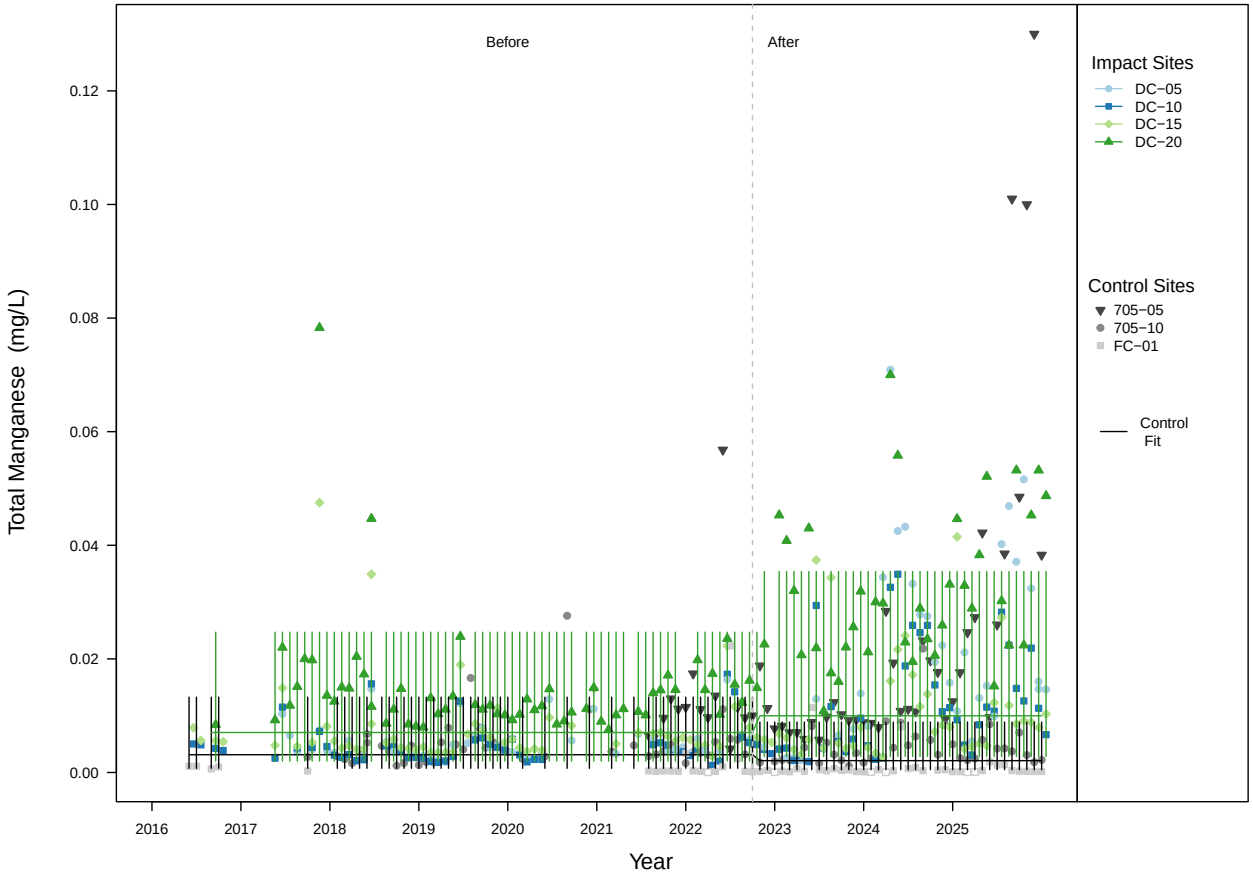
Impact vs.	Estimate	Significance
control sites	0.3281	significant

Conclusion:

The change in Total Manganese concentrations at the impact sites from *before* to *after* was significantly (*adjusted p* = 4.33×10^{-9}) different from the change at the control sites, according to the test on the BACI term (*class:period*).

1.5 Model Summary

The overall performance of the model is shown in the plot below. All the observations are plotted along with the model estimates. The model fitted values and 95% confidence intervals are indicated as lines and errors.



Note: Open symbols represent cases where the results were below the sample detection limit. Model fitted values are based on site class and period. Error bars indicate 95% confidence intervals. The positions of data along the x-axis are adjusted for legibility. Modelled log-transformed values were converted back to natural scale.

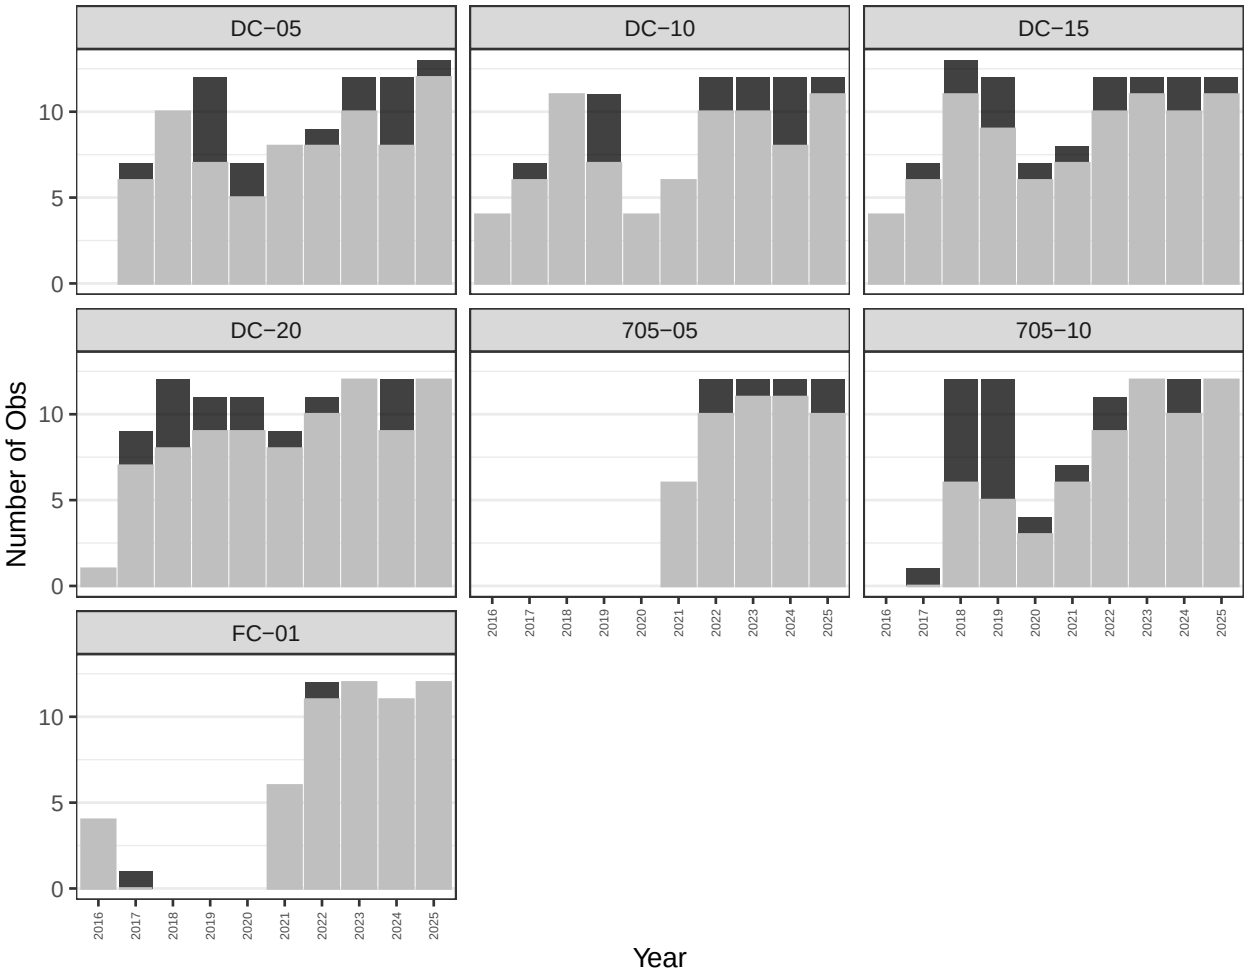
Final Summary Table

Variable	Total Manganese
Watershed	Davidson Creek
Waterbody	Stream
Streams Removed	None
Data Transformation	Log-10 transformed
Model Type	Linear Mixed Effects Regression
Is BACI significant	Yes

A-12.1.21 Total Mercury

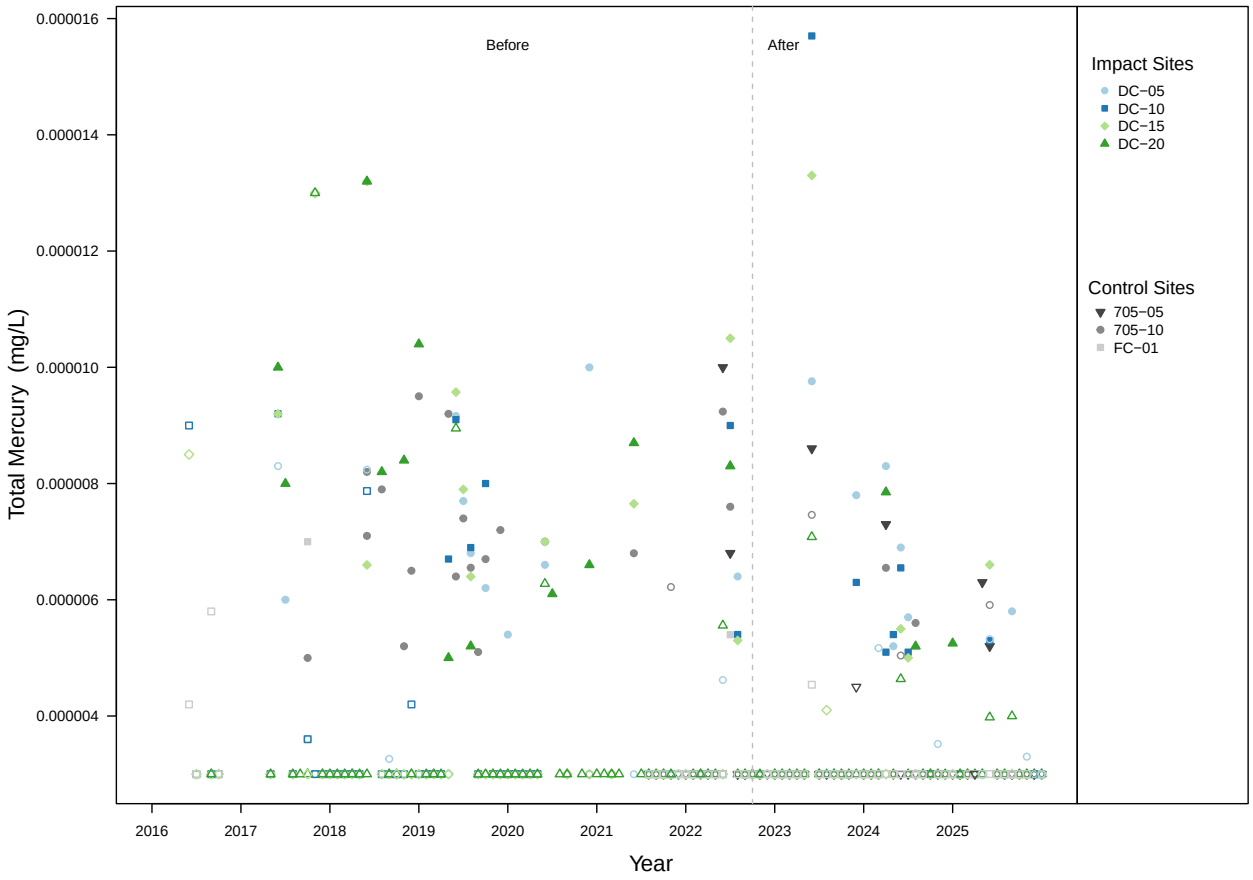
1 Davidson Creek

1.1 Censored Data The following charts indicate the number of measurements taken in each year from each stream that were below the detection limit (light gray) or above the detection limit (dark gray).



Conclusion:

Statistical analyses were not conducted due to censoring or availability of observations. Below is a summary figure of all observations in the dataset.



Note: Open symbols represent cases where the results were below the sample detection limit.

Final Summary Table

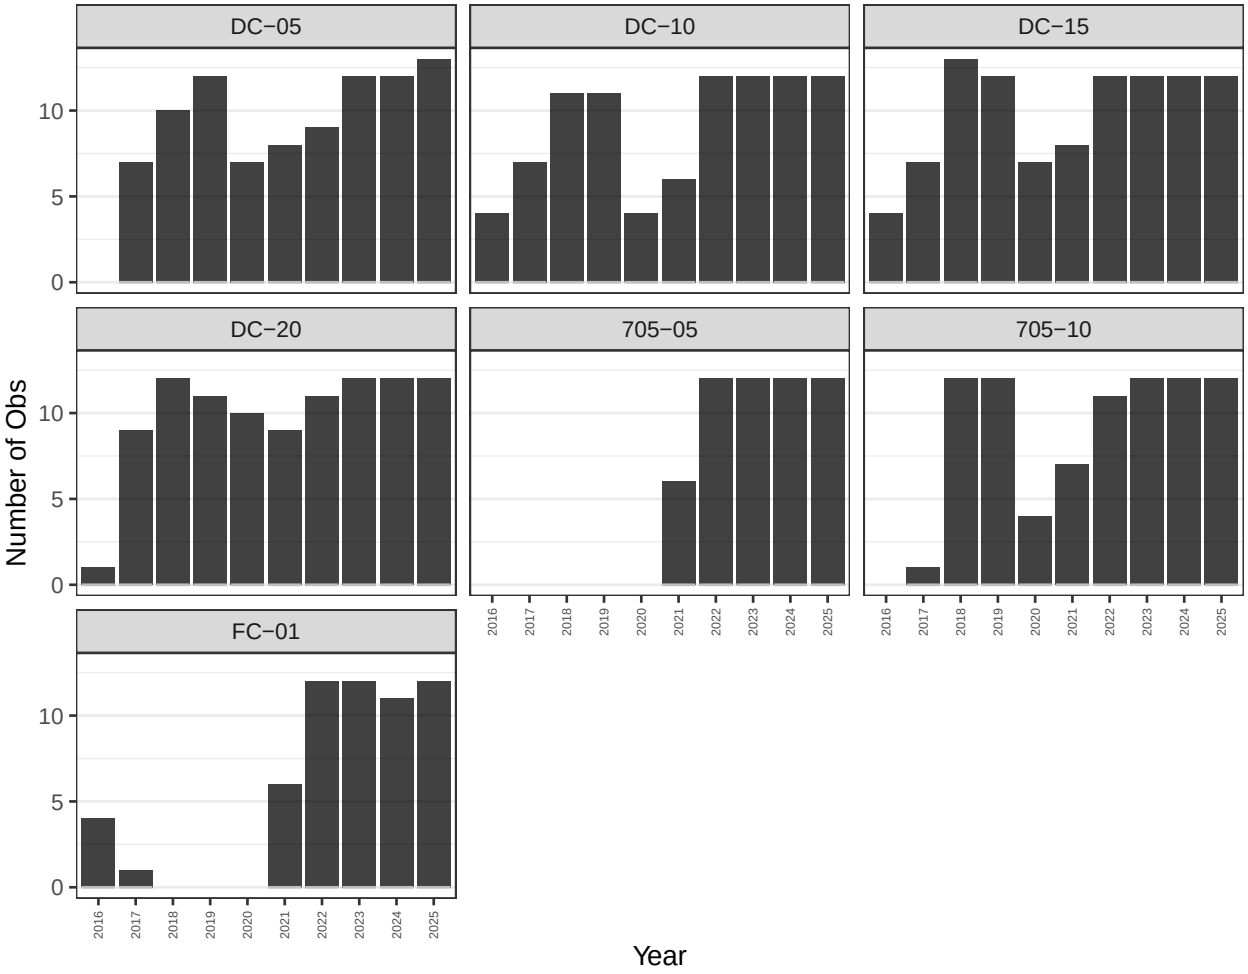
Variable	Total Mercury
Watershed	Davidson Creek
Waterbody	Stream
Streams Removed	All Excluded
Data Transformation	N/A
Model Type	N/A
Benchmark	None
Significant BACI term	N/A

A-12.1.22 Total Molybdenum

1 Davidson Creek

1.1 Censored Data

The following charts indicate the number of measurements taken in each year from each stream that were below the detection limit (light gray) or above the detection limit (dark gray).



Observations at or below the analytical detection limit were considered censored. Data were excluded from the analysis if greater than 70% of observations from a site were censored or if greater than 50% of observations in a site's sampling year were censored. If more than 10% of observations from a site in a sampling year were censored, data were flagged to caution interpretation of results. The following observations were excluded:

None

1.2 Sample Sizes for Modelling

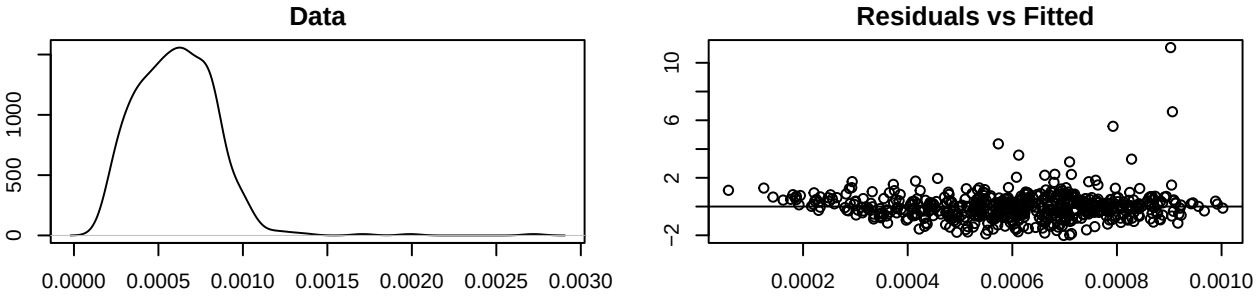
The remaining sample sizes per site and period are summarised in the table below.

Watershed	Site	Period	N	Median	% Censored
Davidson Creek	DC-05	before	51	0.0006	0
Davidson Creek	DC-05	after	39	0.0007	0
Davidson Creek	DC-10	before	52	0.0006	0
Davidson Creek	DC-10	after	39	0.0008	0
Davidson Creek	DC-15	before	60	0.0006	0
Davidson Creek	DC-15	after	39	0.0008	0
Davidson Creek	DC-20	before	61	0.0006	0
Davidson Creek	DC-20	after	38	0.0007	0
Creek 705 (Control)	705-05	before	15	0.0005	0
Creek 705 (Control)	705-05	after	39	0.0006	0
Creek 705 (Control)	705-10	before	45	0.0004	0
Creek 705 (Control)	705-10	after	38	0.0005	0
Fawnie Creek (Control)	FC-01	before	20	0.0005	0
Fawnie Creek (Control)	FC-01	after	38	0.0007	0

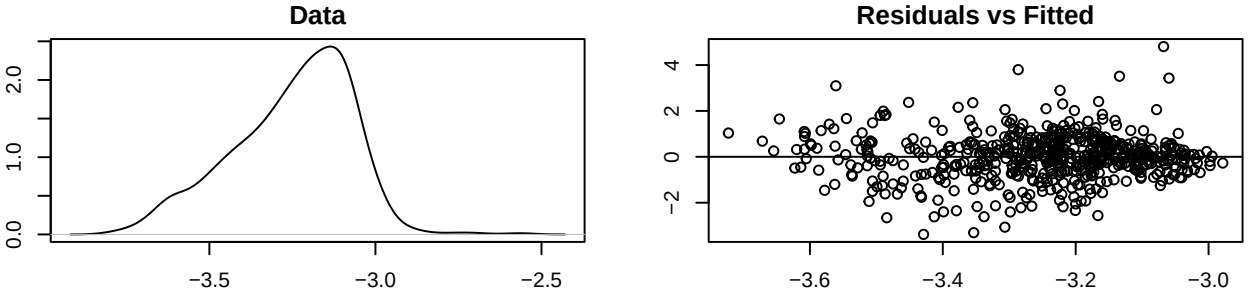
1.3 Initial Model Fit

Initially a model was fit to all sites to assess the need for transformations.

Natural Scale Model



Log−10 Transformed Model



Outliers

The following is a summary of outliers identified (if any) using preliminary regression models. All data points were plotted in the summary figures. The analysis needs to be interpreted with care and in conjunction with graphical displays if large outliers are present.

Outliers on natural scale:

Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Davidson Creek	DC-05	2023	8	impact	after	0.0027	0.0009	11.057	Y
Davidson Creek	DC-10	2023	8	impact	after	0.0020	0.0009	6.595	Y
Davidson Creek	DC-15	2020	3	impact	before	0.0017	0.0008	5.582	Y
Creek 705 (Control)	705-10	2020	2	control	before	0.0013	0.0006	4.360	Y
Davidson Creek	DC-15	2021	10	impact	before	0.0012	0.0006	3.576	Y
Davidson Creek	DC-10	2024	1	impact	after	0.0014	0.0008	3.297	Y
Davidson Creek	DC-20	2022	4	impact	before	0.0012	0.0007	3.106	Y

Outliers on log scale:

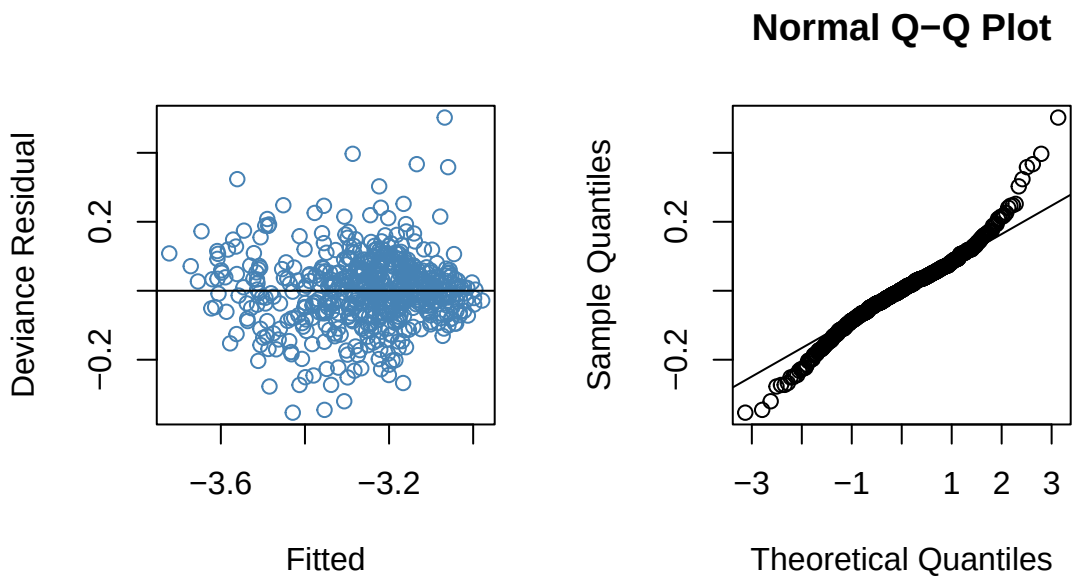
Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Davidson Creek	DC-05	2023	8	impact	after	-2.565	-3.068	4.805	Y
Creek 705 (Control)	705-10	2020	2	control	before	-2.889	-3.287	3.799	Y
Davidson Creek	DC-15	2020	3	impact	before	-2.767	-3.134	3.512	Y
Davidson Creek	DC-10	2023	8	impact	after	-2.701	-3.060	3.429	Y
Davidson Creek	DC-10	2022	6	impact	before	-3.783	-3.429	-3.382	Y
Davidson Creek	DC-05	2020	11	impact	before	-3.699	-3.353	-3.305	Y
Fawnie Creek (Control)	FC-01	2022	5	control	before	-3.237	-3.561	3.096	Y
Davidson Creek	DC-05	2022	7	impact	before	-3.627	-3.307	-3.066	Y

Based on examination of the residuals, the log-10 transformed data were selected for analysis. No outliers were removed prior to analysis.

1.4 Before-After Control-Impact Linear Modeling

A models was fit to compare impact sites with control sites.

Plot of Standardized Residuals and Fitted Values



Results of the ANOVA test on the fixed effects of the model:

	Sum Sq.	Mean Sq.	NumDF	DenDF	F value	p	p adjusted
class	0.30934	0.30934	1	5.294	28.311	0.00264	
period	0.42764	0.42764	1	67.600	39.139	<0.001	
class:period	0.06483	0.06483	1	554.867	5.933	0.0152	0.0233

Results of the observed power calculation for the between-effect test on the fixed effects for repeated-measures ANOVA analysis at a significance level of 0.05:

Sample Size	Effect Size (f2)	Expected Power	Power Test
574	0.2777	100%	Repeated-Measures ANOVA

Summary of BACI contrasts for relative difference between changes from the *before* to *after* in impact sites (DC-05, DC-10, DC-15, DC-20) and control sites (705-05, 705-10, FC-01), with p value adjusted for multiple comparisons:

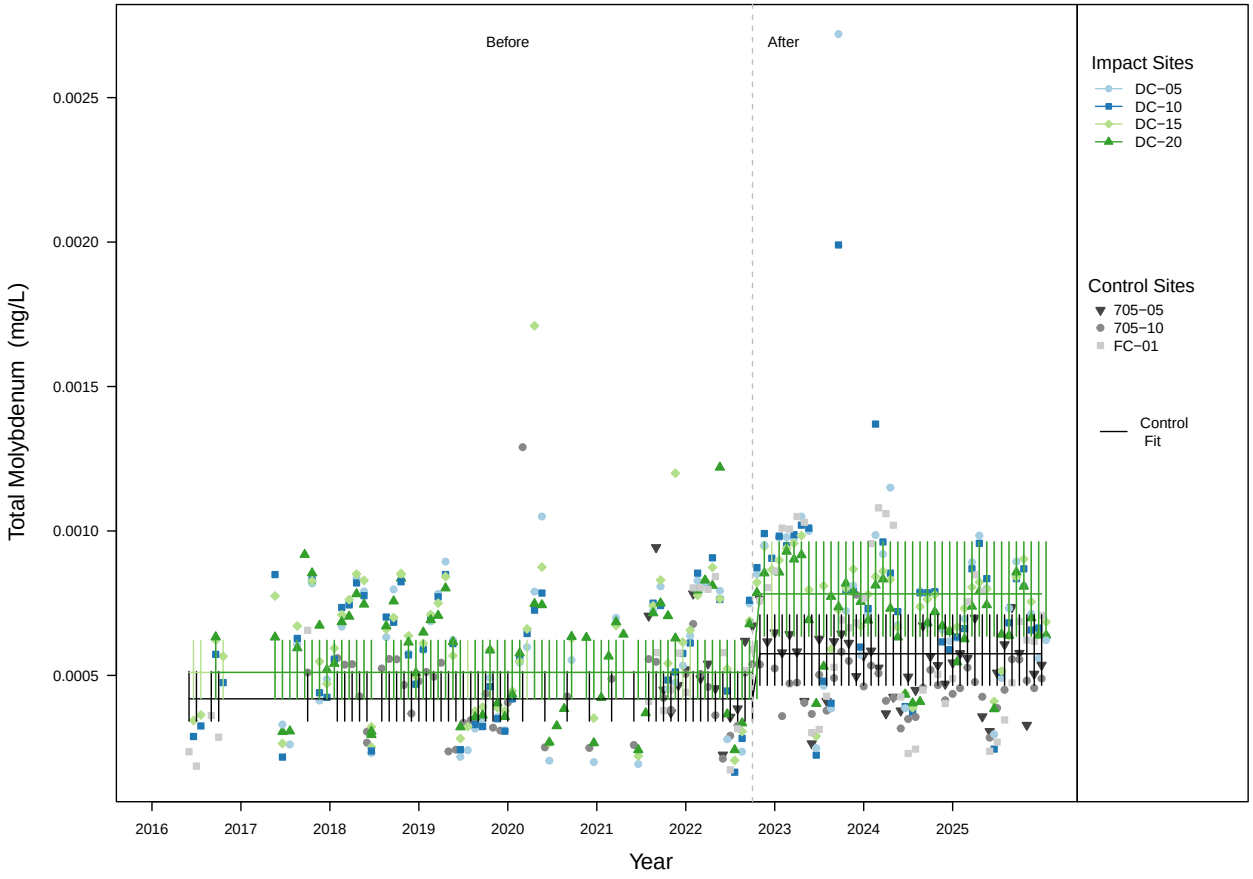
Impact vs.	Estimate	Significance
control sites	0.0479	significant

Conclusion:

The change in Total Molybdenum concentrations at the impact sites from *before* to *after* was significantly (*adjusted p* = 0.0233) different from the change at the control sites, according to the test on the BACI term (*class:period*).

1.5 Model Summary

The overall performance of the model is shown in the plot below. All the observations are plotted along with the model estimates. The model fitted values and 95% confidence intervals are indicated as lines and errors.



Note: Model fitted values are based on site class and period. Error bars indicate 95% confidence intervals. The positions of data along the x-axis are adjusted for legibility. Modelled log-transformed values were converted back to natural scale.

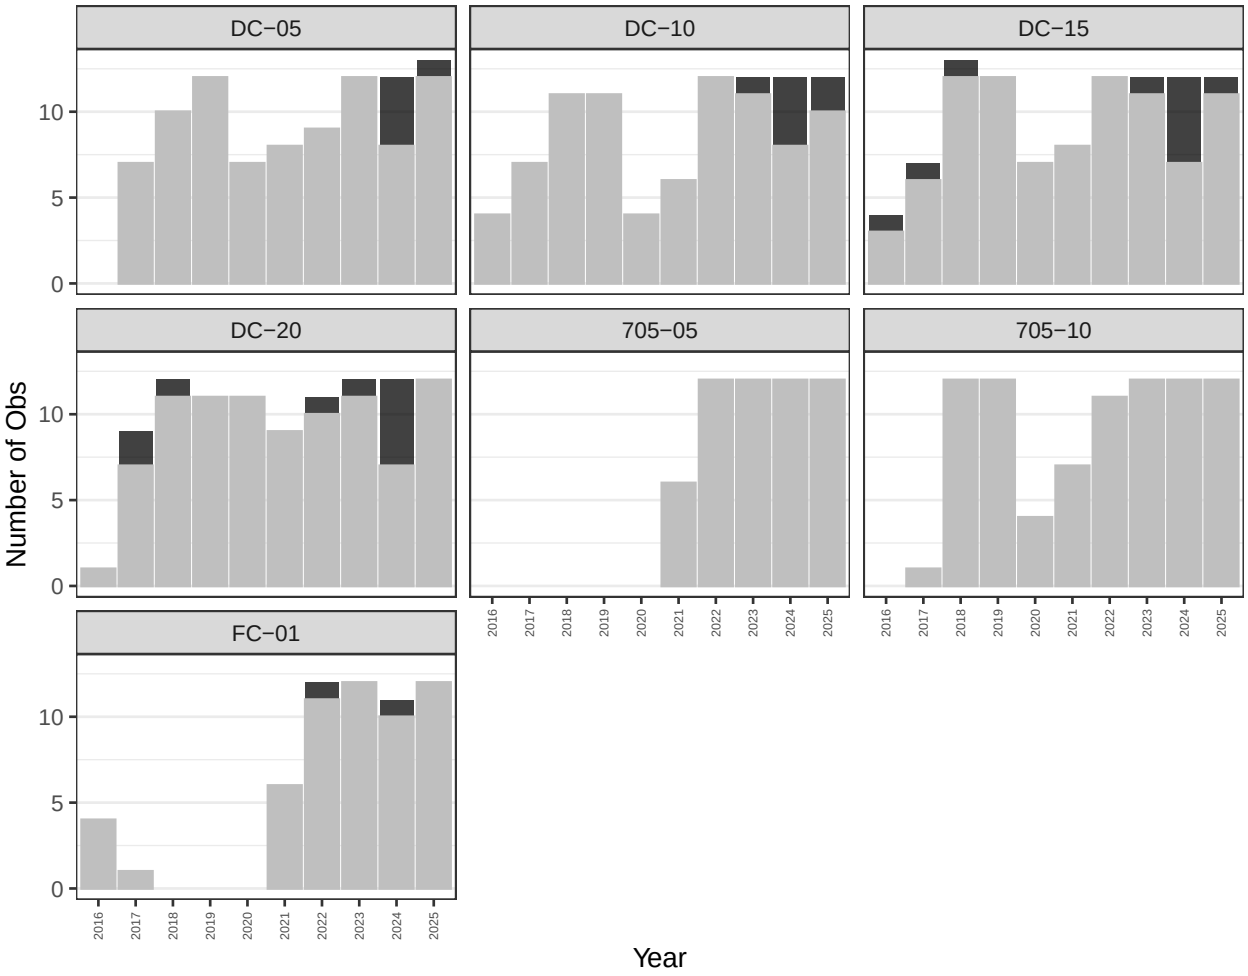
Final Summary Table

Variable	Total Molybdenum
Watershed	Davidson Creek
Waterbody	Stream
Streams Removed	None
Data Transformation	Log-10 transformed
Model Type	Linear Mixed Effects Regression
Is BACI significant	Yes

A-12.1.23 Total Nickel

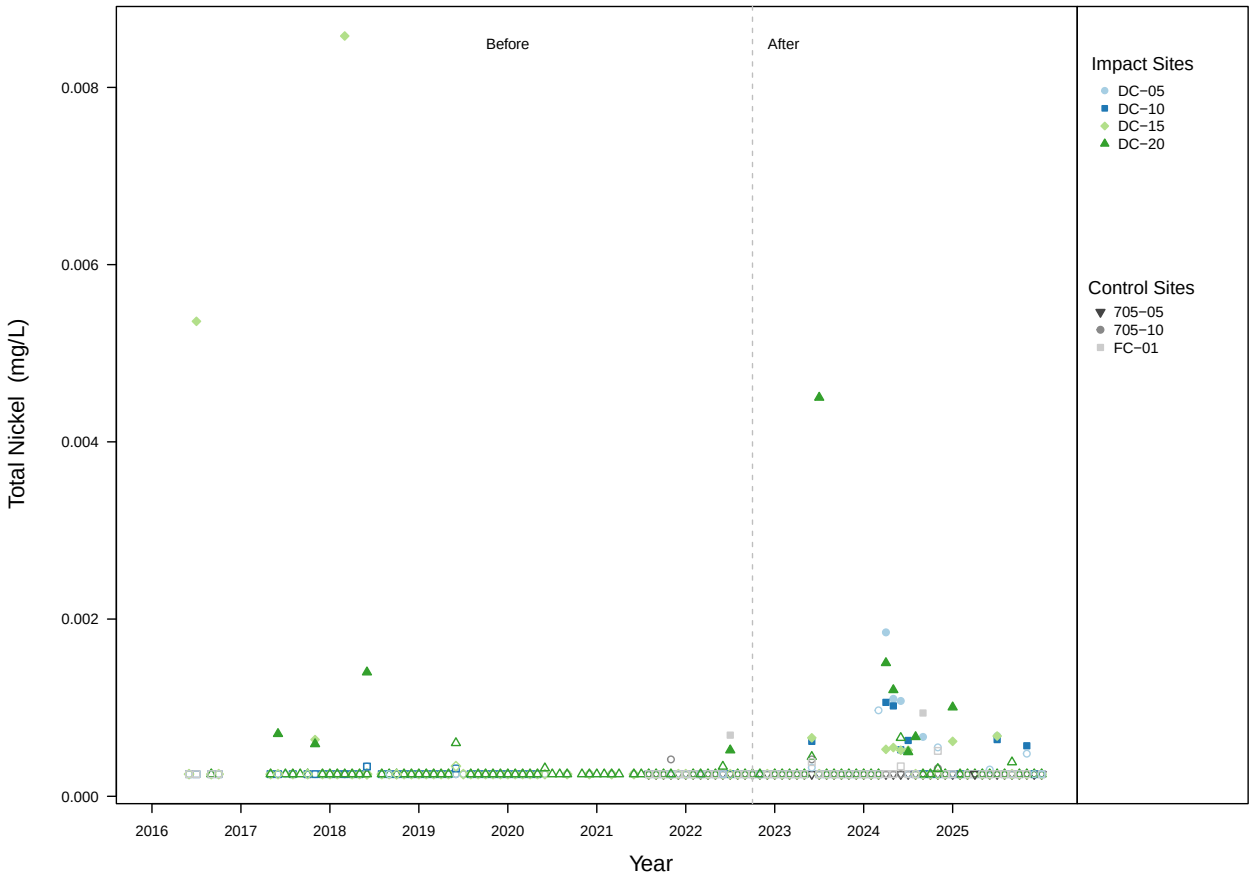
1 Davidson Creek

1.1 Censored Data The following charts indicate the number of measurements taken in each year from each stream that were below the detection limit (light gray) or above the detection limit (dark gray).



Conclusion:

Statistical analyses were not conducted due to censoring or availability of observations. Below is a summary figure of all observations in the dataset.



Note: Open symbols represent cases where the results were below the sample detection limit.

Final Summary Table

Variable	Total Nickel
Watershed	Davidson Creek

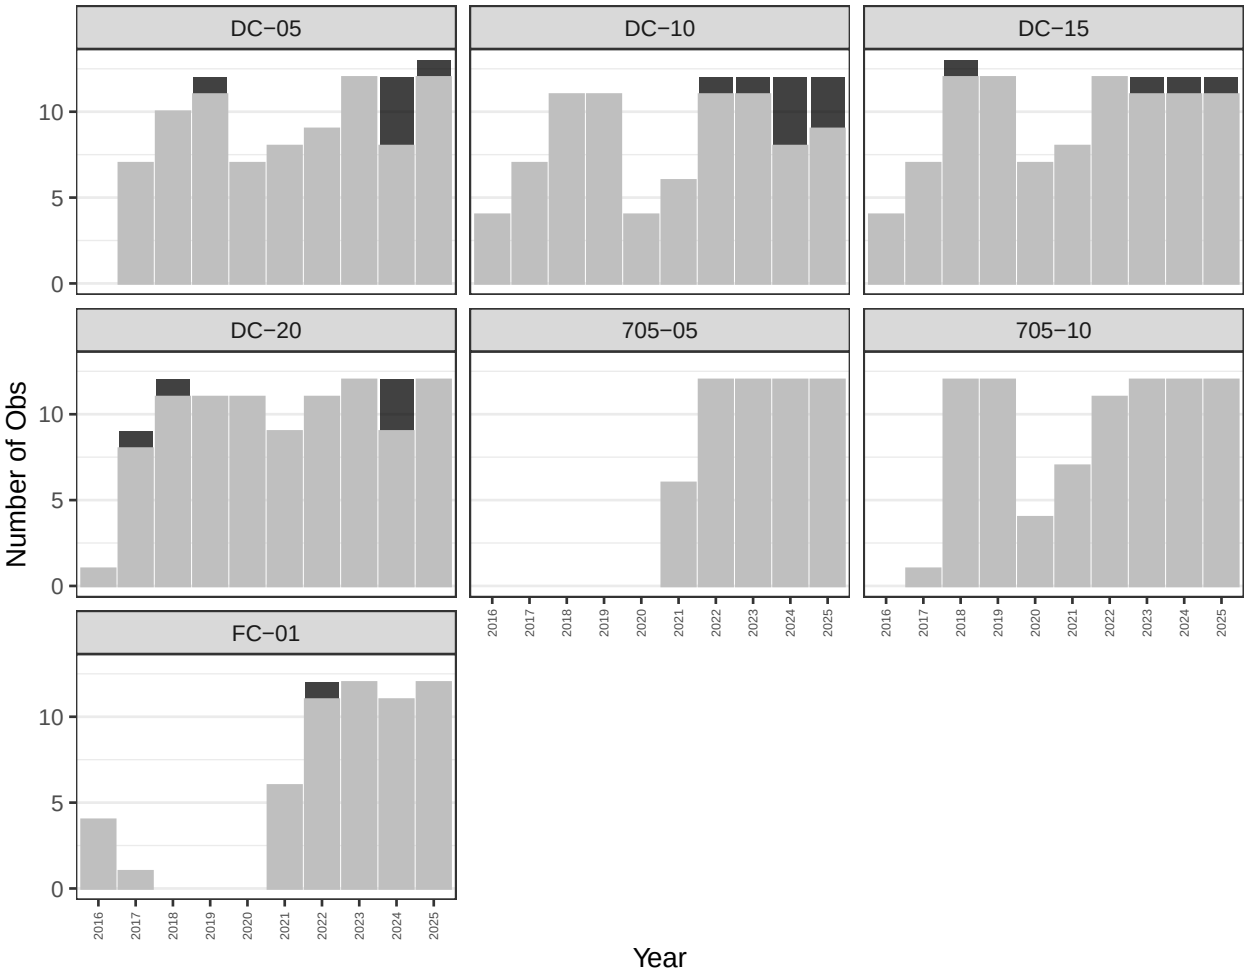
A-12.1.24 Total Silver

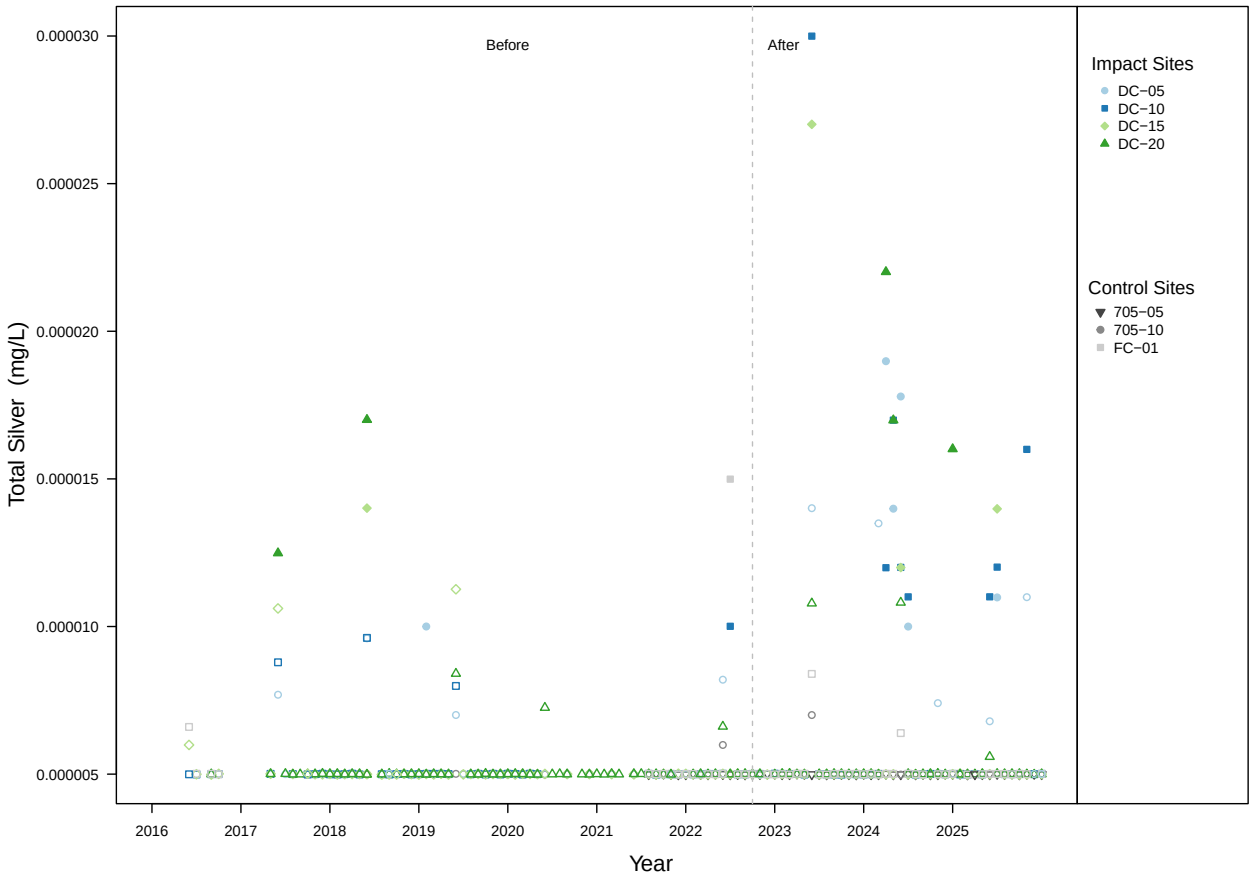
1 Davidson Creek

1.1 Censored Data The following charts indicate the number of measurements taken in each year from each stream that were below the detection limit (light gray) or above the detection limit (dark gray).



Conclusion:

Statistical analyses were not conducted due to censoring or availability of observations. Below is a summary figure of all observations in the dataset.



Note: Open symbols represent cases where the results were below the sample detection limit.

Final Summary Table

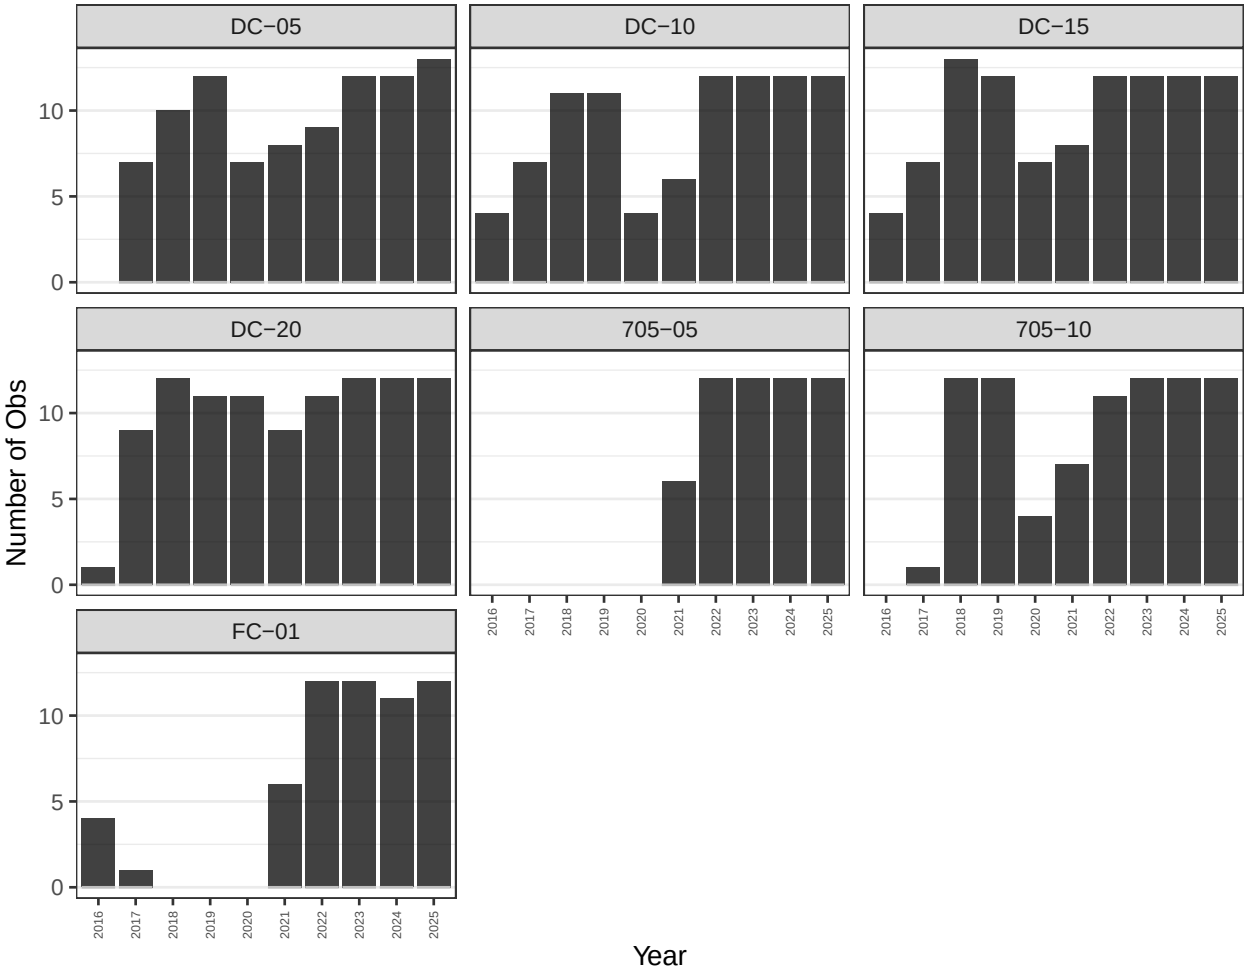
Variable	Total Silver
Watershed	Davidson Creek
Waterbody	Stream
Streams Removed	All Excluded
Data Transformation	N/A
Model Type	N/A
Benchmark	None
Significant BACI term	N/A

A-12.1.25 Total Strontium

1 Davidson Creek

1.1 Censored Data

The following charts indicate the number of measurements taken in each year from each stream that were below the detection limit (light gray) or above the detection limit (dark gray).



Observations at or below the analytical detection limit were considered censored. Data were excluded from the analysis if greater than 70% of observations from a site were censored or if greater than 50% of observations in a site's sampling year were censored. If more than 10% of observations from a site in a sampling year were censored, data were flagged to caution interpretation of results. The following observations were excluded:

None

1.2 Sample Sizes for Modelling

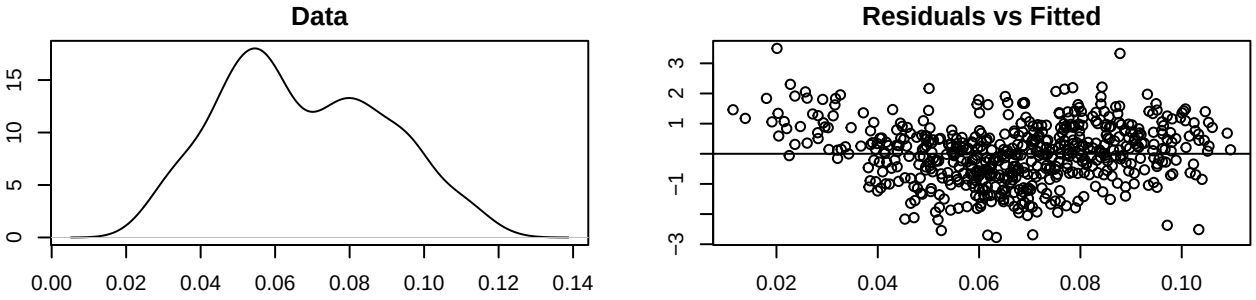
The remaining sample sizes per site and period are summarised in the table below.

Watershed	Site	Period	N	Median	% Censored
Davidson Creek	DC-05	before	51	0.0626	0
Davidson Creek	DC-05	after	39	0.0795	0
Davidson Creek	DC-10	before	52	0.0672	0
Davidson Creek	DC-10	after	39	0.0837	0
Davidson Creek	DC-15	before	60	0.0725	0
Davidson Creek	DC-15	after	39	0.0934	0
Davidson Creek	DC-20	before	62	0.0759	0
Davidson Creek	DC-20	after	38	0.0925	0
Creek 705 (Control)	705-05	before	15	0.0490	0
Creek 705 (Control)	705-05	after	39	0.0555	0
Creek 705 (Control)	705-10	before	45	0.0567	0
Creek 705 (Control)	705-10	after	38	0.0589	0
Fawnie Creek (Control)	FC-01	before	20	0.0459	0
Fawnie Creek (Control)	FC-01	after	38	0.0494	0

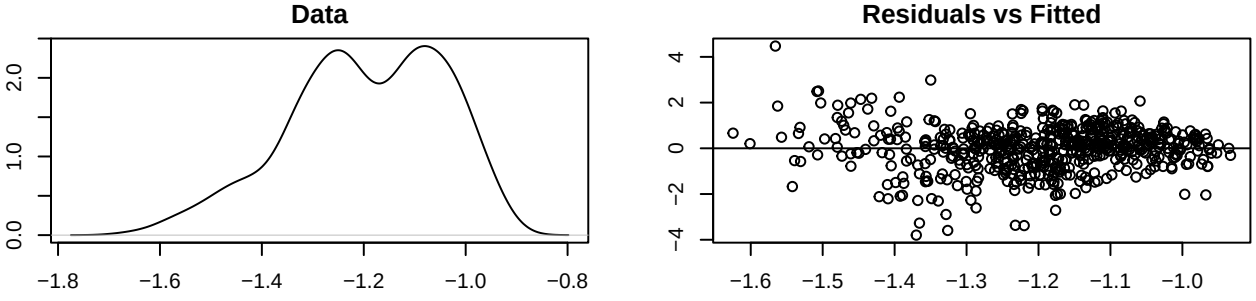
1.3 Initial Model Fit

Initially a model was fit to all sites to assess the need for transformations.

Natural Scale Model



Log−10 Transformed Model



Outliers

The following is a summary of outliers identified (if any) using preliminary regression models. All data points were plotted in the summary figures. The analysis needs to be interpreted with care and in conjunction with graphical displays if large outliers are present.

Outliers on natural scale:

Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Fawnie Creek (Control)	FC-01	2022	5	control	before	0.056	0.0201	3.495	Y
Davidson Creek	DC-05	2024	1	impact	after	0.122	0.0878	3.328	Y

Outliers on log scale:

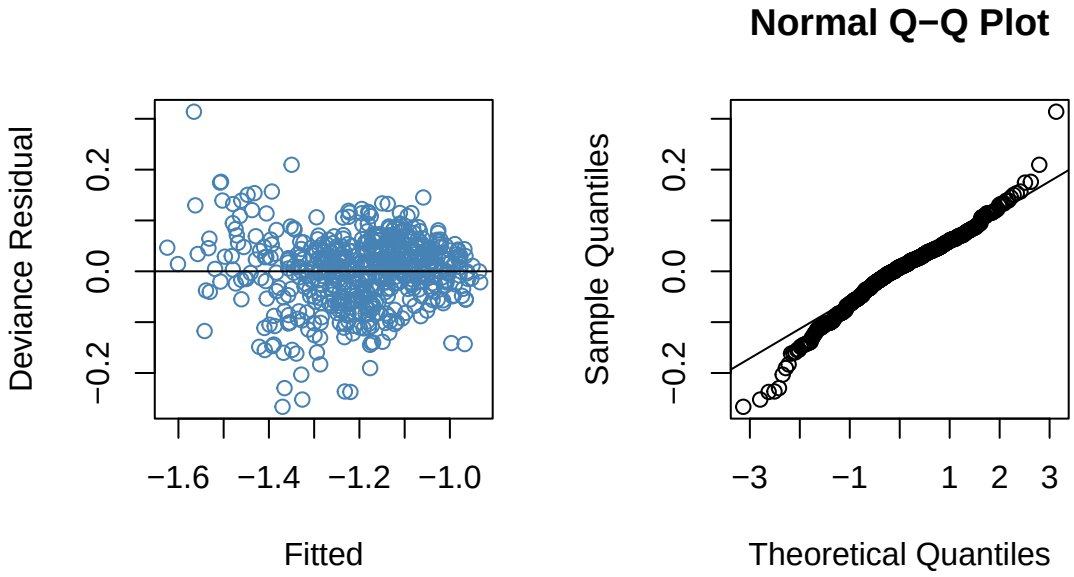
Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Fawnie Creek (Control)	FC-01	2022	5	control	before	-1.252	-1.566	4.472	Y
Davidson Creek	DC-10	2022	6	impact	before	-1.636	-1.370	-3.796	Y
Davidson Creek	DC-15	2022	6	impact	before	-1.578	-1.326	-3.593	Y
Davidson Creek	DC-10	2022	7	impact	before	-1.457	-1.220	-3.380	Y
Davidson Creek	DC-05	2022	7	impact	before	-1.468	-1.232	-3.367	Y
Davidson Creek	DC-15	2018	5	impact	before	-1.595	-1.365	-3.272	Y

Based on examination of the residuals, the log-10 transformed data were selected for analysis. No outliers were removed prior to analysis.

1.4 Before-After Control-Impact Linear Modeling

A models was fit to compare impact sites with control sites.

Plot of Standardized Residuals and Fitted Values



Results of the ANOVA test on the fixed effects of the model:

	Sum Sq.	Mean Sq.	NumDF	DenDF	F value	p	p adjusted
class	0.13856	0.13856	1	5.059	28.12	0.00308	
period	0.26931	0.26931	1	69.775	54.65	<0.001	
class:period	0.09479	0.09479	1	553.758	19.23	<0.001	3.72e-05

Results of the observed power calculation for the between-effect test on the fixed effects for repeated-measures ANOVA analysis at a significance level of 0.05:

Sample Size	Effect Size (f2)	Expected Power	Power Test
575	0.4834	100%	Repeated-Measures ANOVA

Summary of BACI contrasts for relative difference between changes from the *before* to *after* in impact sites (DC-05, DC-10, DC-15, DC-20) and control sites (705-05, 705-10, FC-01), with p value adjusted for multiple comparisons:

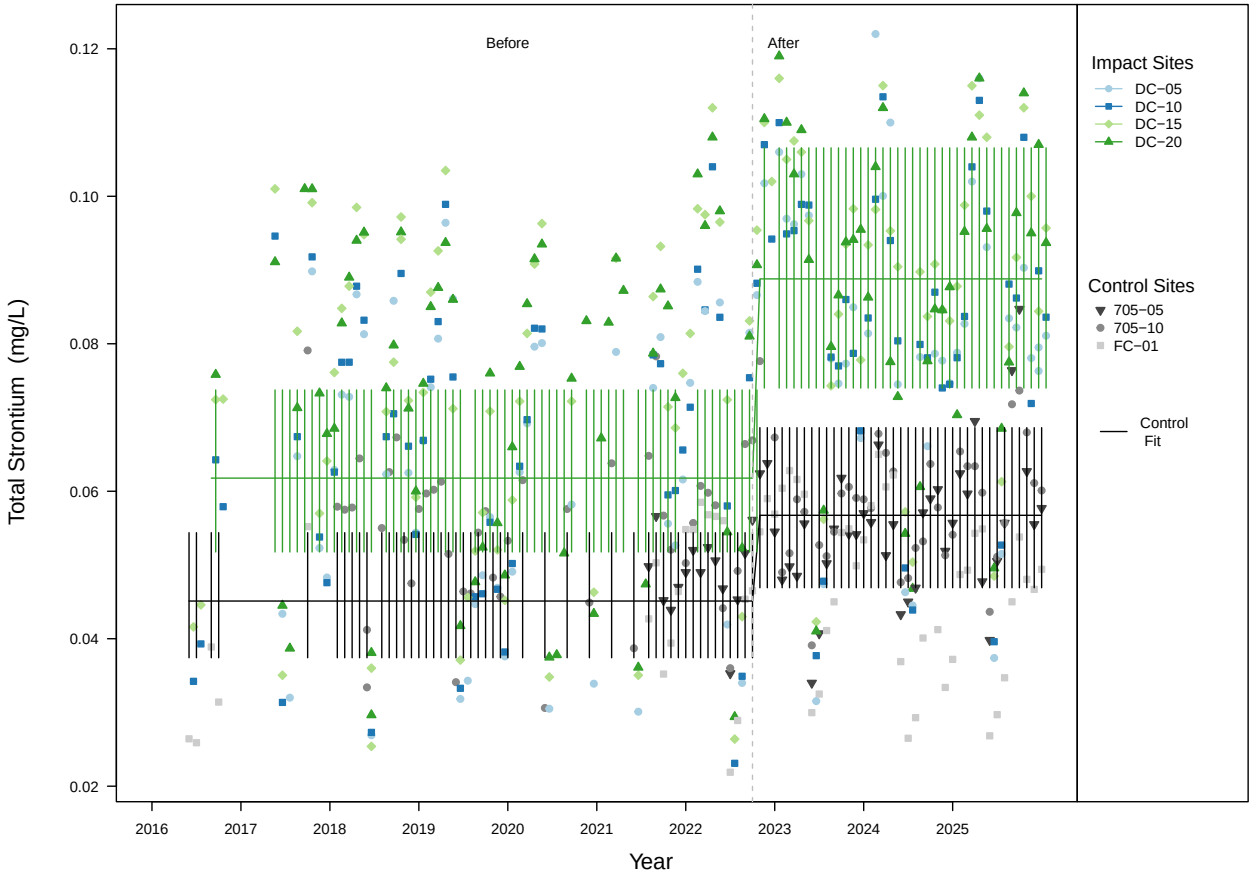
Impact vs.	Estimate	Significance
control sites	0.058	significant

Conclusion:

The change in Total Strontium concentrations at the impact sites from *before* to *after* was significantly (*adjusted p* = 3.72×10^{-5}) different from the change at the control sites, according to the test on the BACI term (*class:period*).

1.5 Model Summary

The overall performance of the model is shown in the plot below. All the observations are plotted along with the model estimates. The model fitted values and 95% confidence intervals are indicated as lines and errors.



Note: Model fitted values are based on site class and period. Error bars indicate 95% confidence intervals. The positions of data along the x-axis are adjusted for legibility. Modelled log-transformed values were converted back to natural scale.

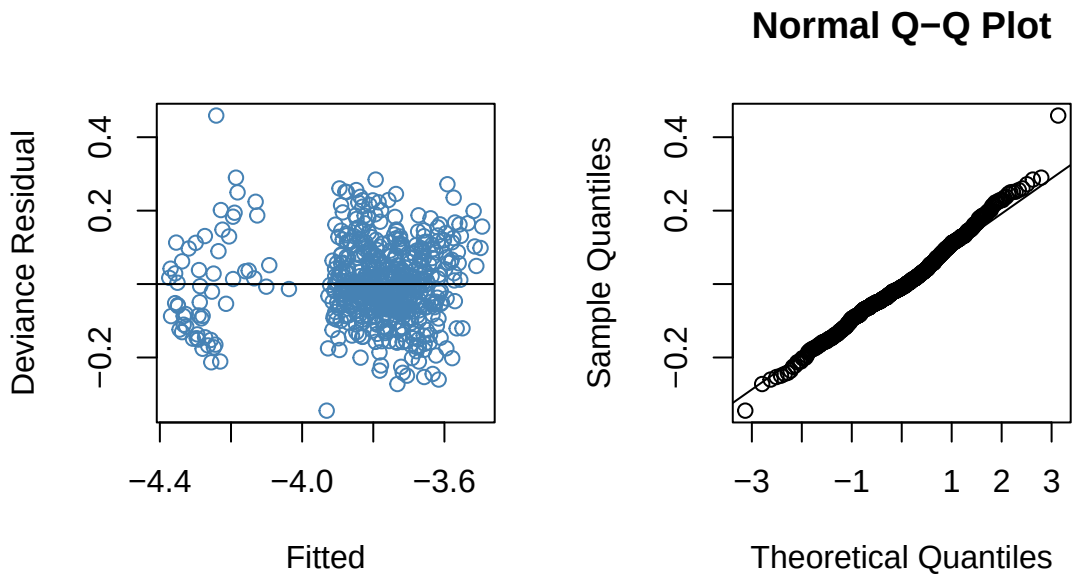
Based on examination of the residuals, the log-10 transformed data were selected for analysis. No outliers were removed prior to analysis.

1.4 Before-After Control-Impact Linear Modeling

A models was fit to compare impact sites with control sites.

Plot of Standardized Residuals and Fitted Values



Results of the ANOVA test on the fixed effects of the model:

	Sum Sq.	Mean Sq.	NumDF	DenDF	F value	p	p adjusted
class	0.01599	0.01599	1	5.03	0.2526	0.636	
period	2.91989	2.91989	1	239.35	46.1216	<0.001	
class:period	1.32371	1.32371	1	550.01	20.9089	<0.001	1.97e-05

Results of the observed power calculation for the between-effect test on the fixed effects for repeated-measures ANOVA analysis at a significance level of 0.05:

Sample Size	Effect Size (f2)	Expected Power	Power Test
575	0.1927	98%	Repeated-Measures ANOVA

Summary of BACI contrasts for relative difference between changes from the *before* to *after* in impact sites (DC-05, DC-10, DC-15, DC-20) and control sites (705-05, 705-10, FC-01), with p value adjusted for multiple comparisons:

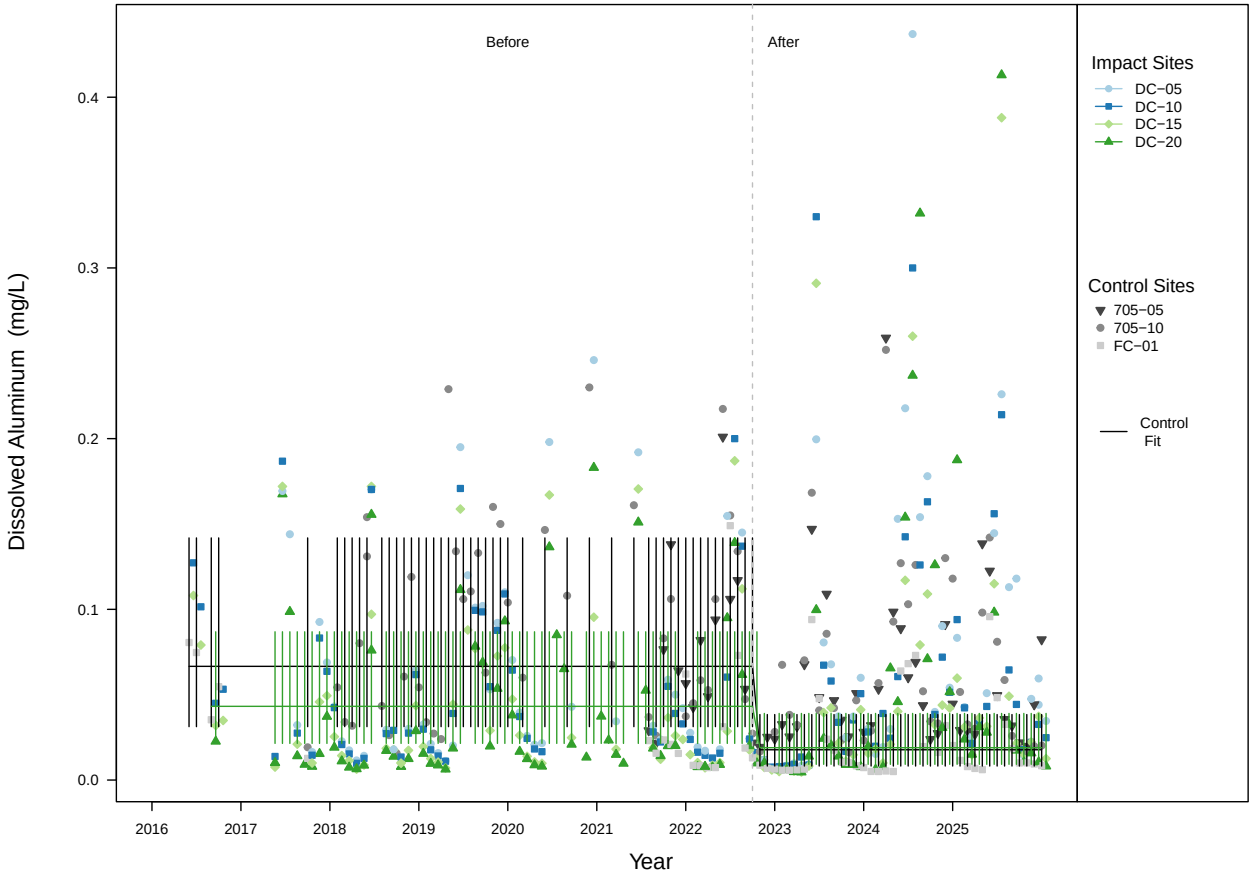
Impact vs.	Estimate	Significance
control sites	0.2169	significant

Conclusion:

The change in Dissolved Aluminum concentrations at the impact sites from *before* to *after* was significantly (*adjusted p* = 1.97×10^{-5}) different from the change at the control sites, according to the test on the BACI term (*class*:*period*).

1.5 Model Summary

The overall performance of the model is shown in the plot below. All the observations are plotted along with the model estimates. The model fitted values and 95% confidence intervals are indicated as lines and errors.



Note: Model fitted values are based on site class and period. Error bars indicate 95% confidence intervals. The positions of data along the x-axis are adjusted for legibility. Modelled log-transformed values were converted back to natural scale.

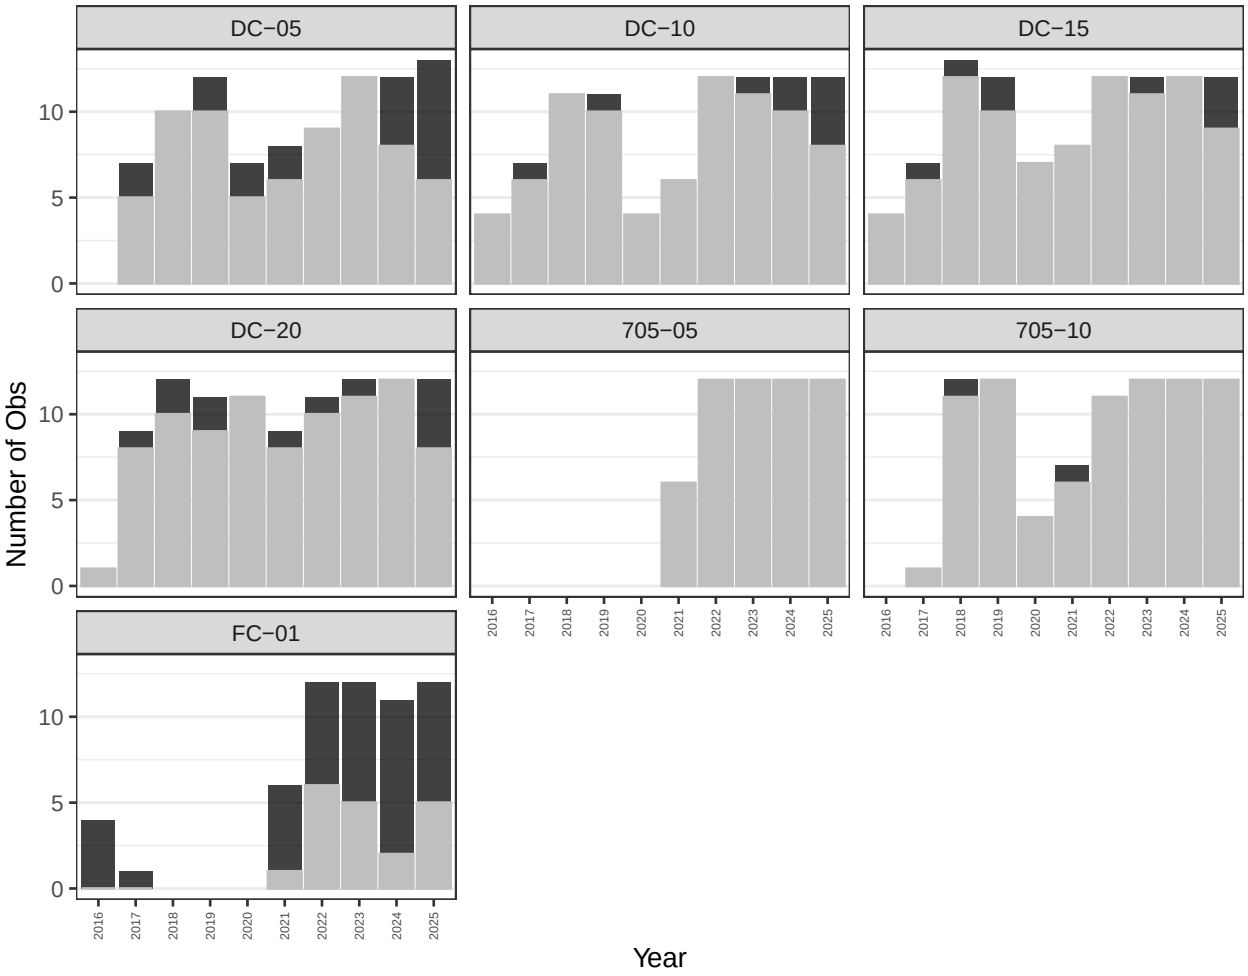
Final Summary Table

Variable	Dissolved Aluminum
Watershed	Davidson Creek
Waterbody	Stream
Streams Removed	None
Data Transformation	Log-10 transformed
Model Type	Linear Mixed Effects Regression
Is BACI significant	Yes

A-12.1.31 Dissolved Cadmium

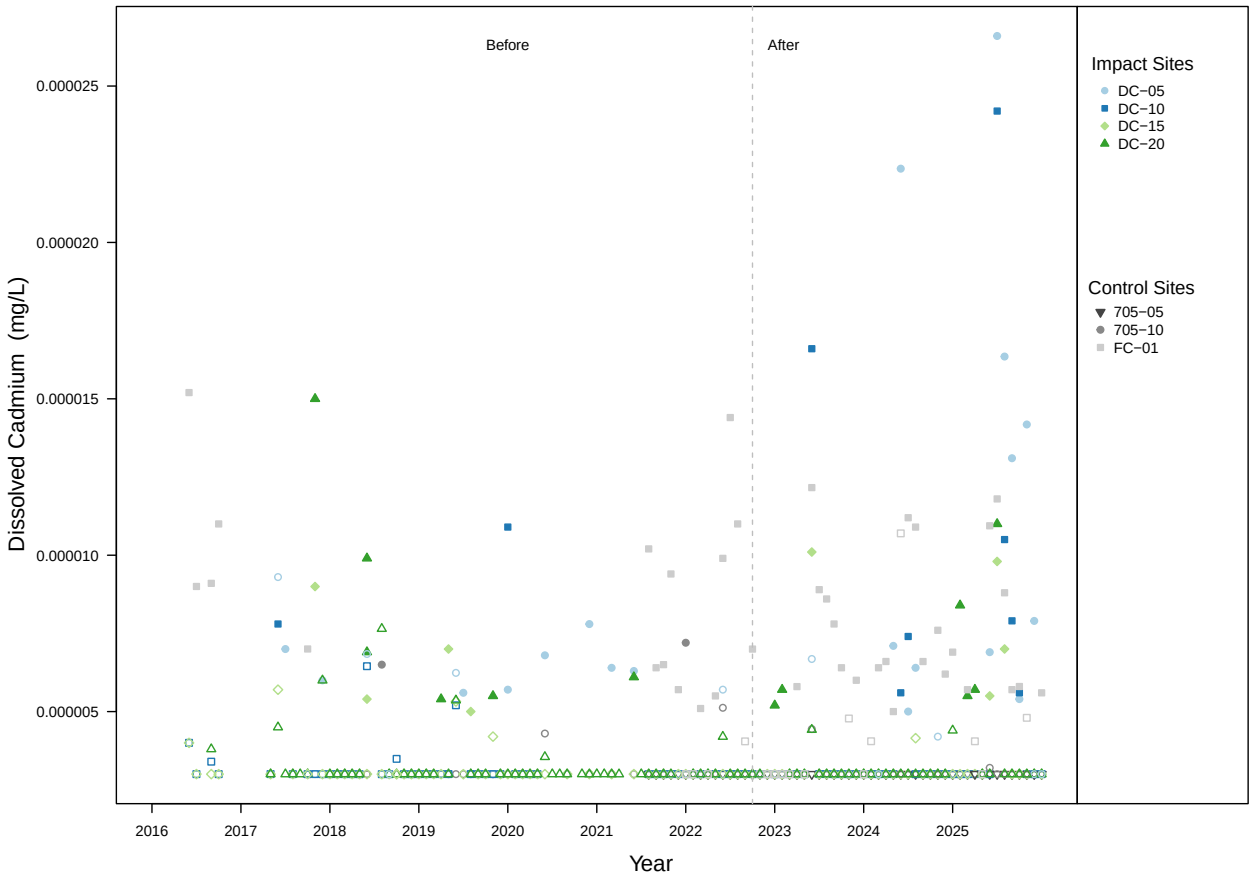
1 Davidson Creek

1.1 Censored Data The following charts indicate the number of measurements taken in each year from each stream that were below the detection limit (light gray) or above the detection limit (dark gray).



Conclusion:

Statistical analyses were not conducted due to censoring or availability of observations. Below is a summary figure of all observations in the dataset.



Note: Open symbols represent cases where the results were below the sample detection limit.

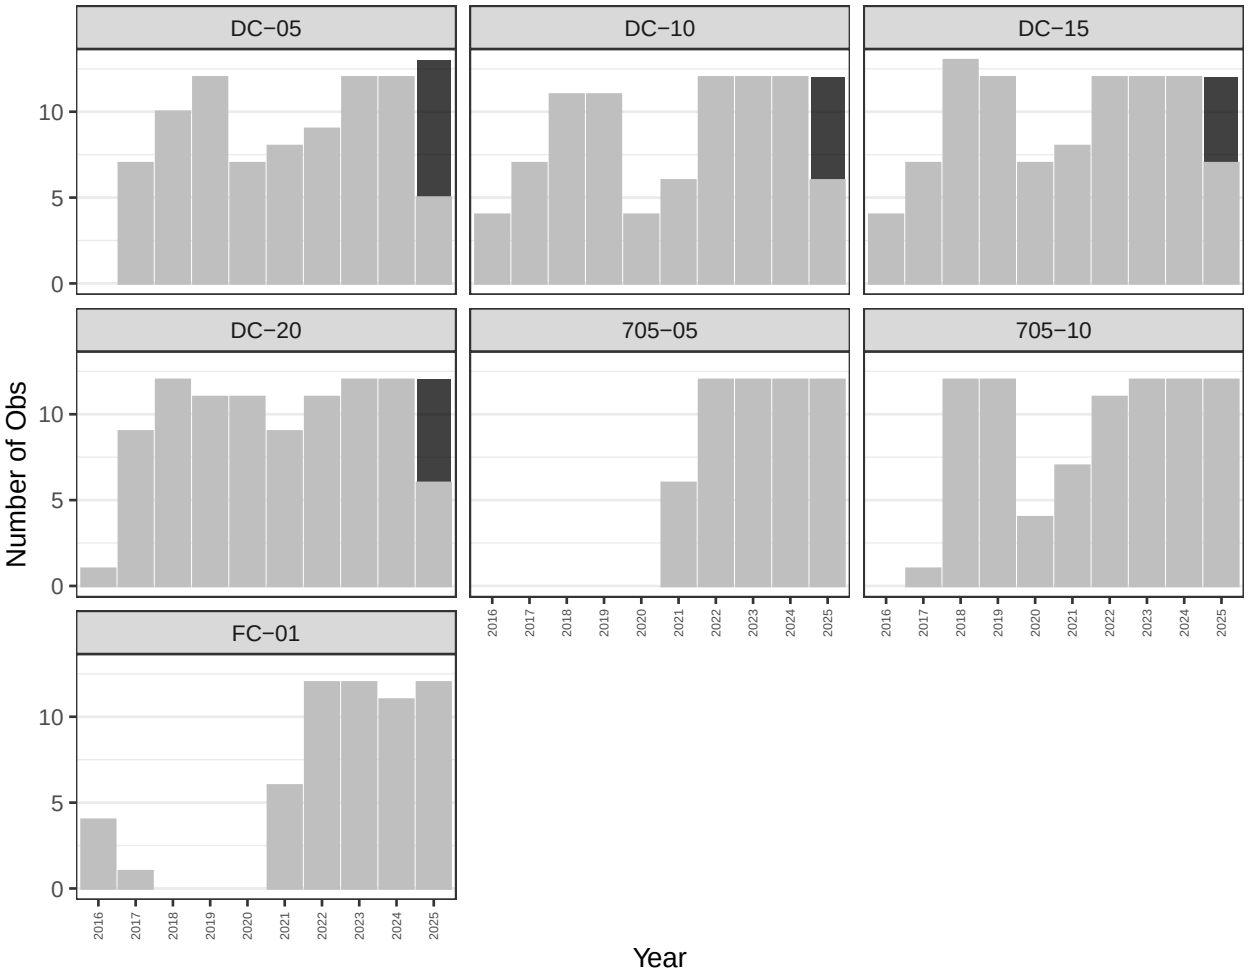
Final Summary Table

Variable	Dissolved Cadmium
Watershed	Davidson Creek
Waterbody	Stream
Streams Removed	All Excluded
Data Transformation	N/A
Model Type	N/A
Benchmark	None
Significant BACI term	N/A

A-12.1.32 Dissolved Cobalt

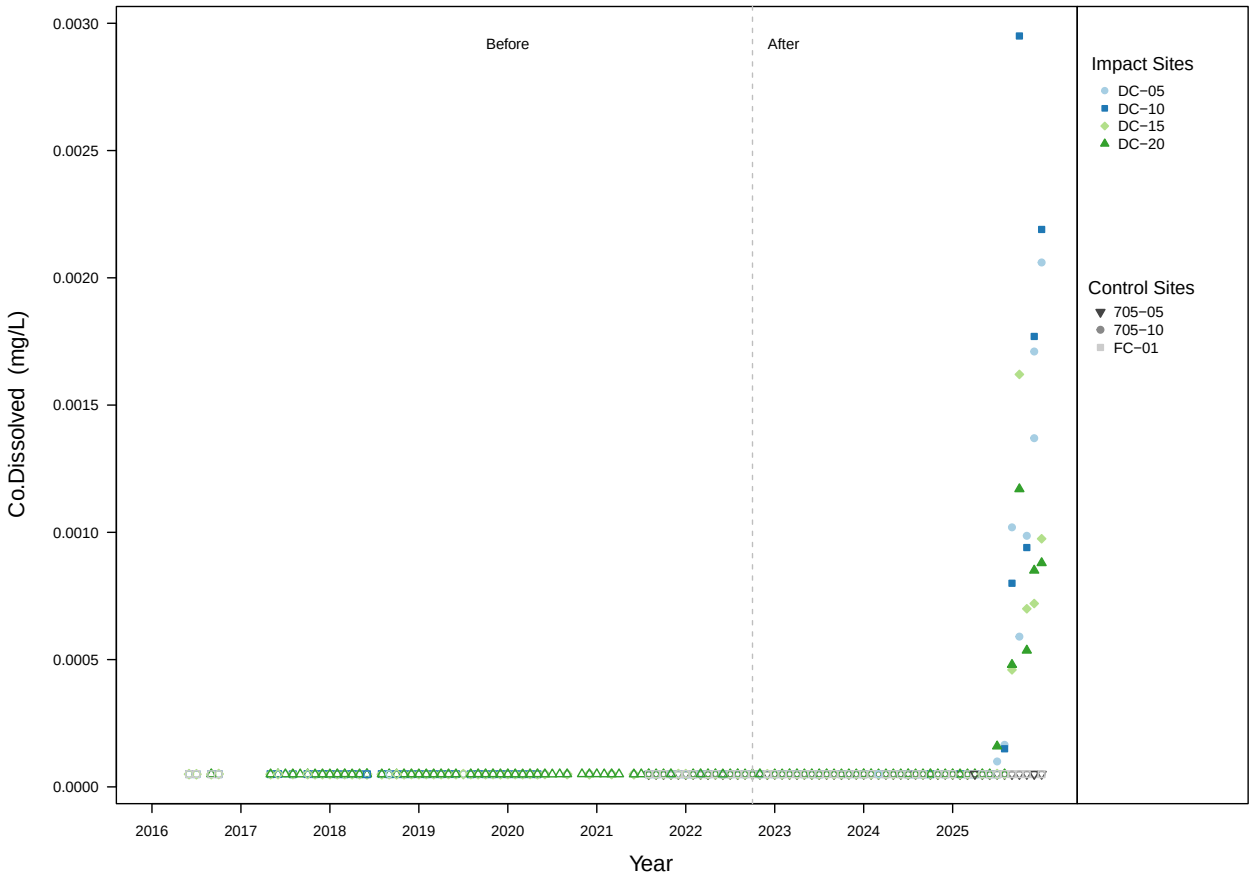
1 Davidson Creek

1.1 Censored Data The following charts indicate the number of measurements taken in each year from each stream that were below the detection limit (light gray) or above the detection limit (dark gray).



Conclusion:

Statistical analyses were not conducted due to censoring or availability of observations. Below is a summary figure of all observations in the dataset.



Note: Open symbols represent cases where the results were below the sample detection limit.

Final Summary Table

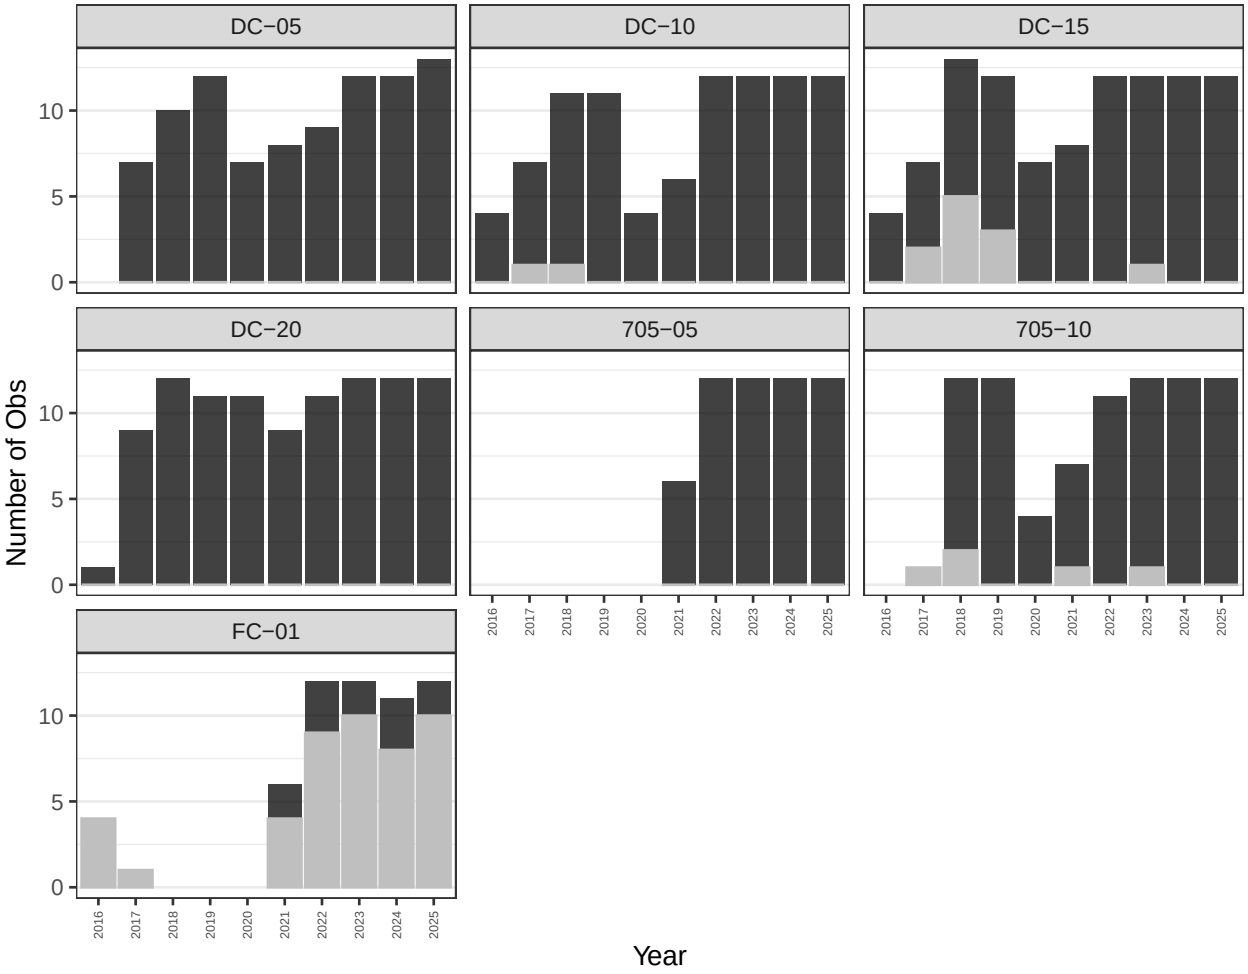
Variable	Co.Dissolved
Watershed	Davidson Creek
Waterbody	Stream
Streams Removed	All Excluded
Data Transformation	N/A
Model Type	N/A
Benchmark	None
Significant BACI term	N/A

A-12.1.33 Dissolved Iron

1 Davidson Creek

1.1 Censored Data

The following charts indicate the number of measurements taken in each year from each stream that were below the detection limit (light gray) or above the detection limit (dark gray).



Observations at or below the analytical detection limit were considered censored. Data were excluded from the analysis if greater than 70% of observations from a site were censored or if greater than 50% of observations in a site's sampling year were censored. If more than 10% of observations from a site in a sampling year were censored, data were flagged to caution interpretation of results. The following observations were excluded:

Watershed	Site	Year	Class	Period	#Obs Removed
Creek 705 (Control)	705-10	2017	control	before	1
Fawnie Creek (Control)	FC-01	2016	control	before	4
Fawnie Creek (Control)	FC-01	2017	control	before	1
Fawnie Creek (Control)	FC-01	2021	control	before	6
Fawnie Creek (Control)	FC-01	2022	control	before	12
Fawnie Creek (Control)	FC-01	2022	control	after	12
Fawnie Creek (Control)	FC-01	2023	control	after	12

(Continued on Next Page...)

(continued)

Watershed	Site	Year	Class	Period	#Obs Removed
Fawnie Creek (Control)	FC-01	2024	control	after	11
Fawnie Creek (Control)	FC-01	2025	control	after	12

1.2 Sample Sizes for Modelling

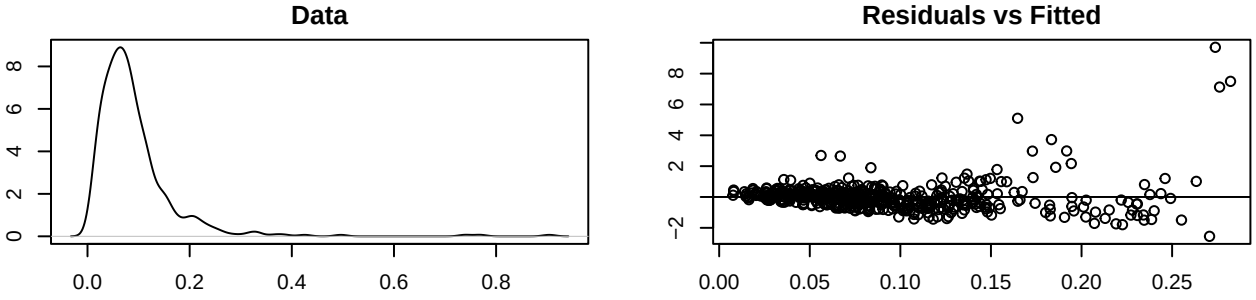
The remaining sample sizes per site and period are summarised in the table below.

Watershed	Site	Period	N	Median	% Censored
Davidson Creek	DC-05	before	51	0.0680	0.000
Davidson Creek	DC-05	after	39	0.0575	0.000
Davidson Creek	DC-10	before	52	0.0575	3.846
Davidson Creek	DC-10	after	39	0.0420	0.000
Davidson Creek	DC-15	before	60	0.0450	16.667
Davidson Creek	DC-15	after	39	0.0350	2.564
Davidson Creek	DC-20	before	62	0.0860	0.000
Davidson Creek	DC-20	after	38	0.1635	0.000
Creek 705 (Control)	705-05	before	15	0.1480	0.000
Creek 705 (Control)	705-05	after	39	0.1590	0.000
Creek 705 (Control)	705-10	before	28	0.0830	7.143

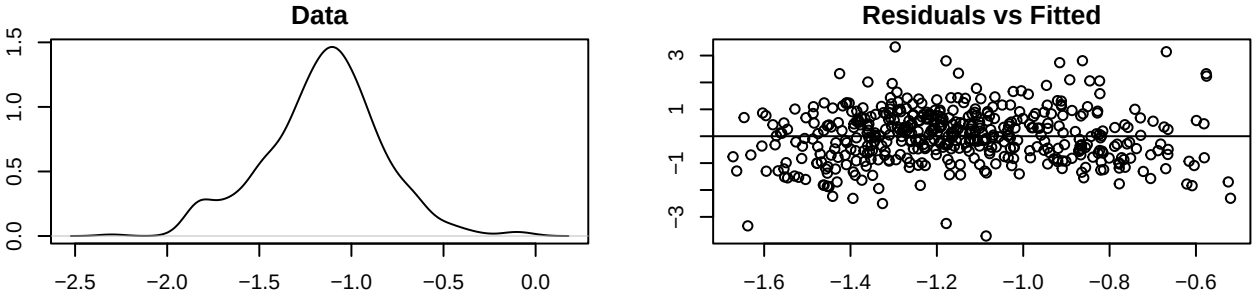
1.3 Initial Model Fit

Initially a model was fit to all sites to assess the need for transformations.

Natural Scale Model



Log−10 Transformed Model



Outliers

The following is a summary of outliers identified (if any) using preliminary regression models. All data points were plotted in the summary figures. The analysis needs to be interpreted with care and in conjunction with graphical displays if large outliers are present.

Outliers on natural scale:

Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Creek 705 (Control)	705-05	2025	9	control	after	0.904	0.2739	9.707	Y
Creek 705 (Control)	705-05	2025	8	control	after	0.769	0.2822	7.499	Y
Creek 705 (Control)	705-05	2025	10	control	after	0.739	0.2762	7.130	Y
Davidson Creek	DC-20	2025	6	impact	after	0.496	0.1647	5.104	Y
Davidson Creek	DC-20	2025	9	impact	after	0.425	0.1834	3.722	Y

Outliers on log scale:

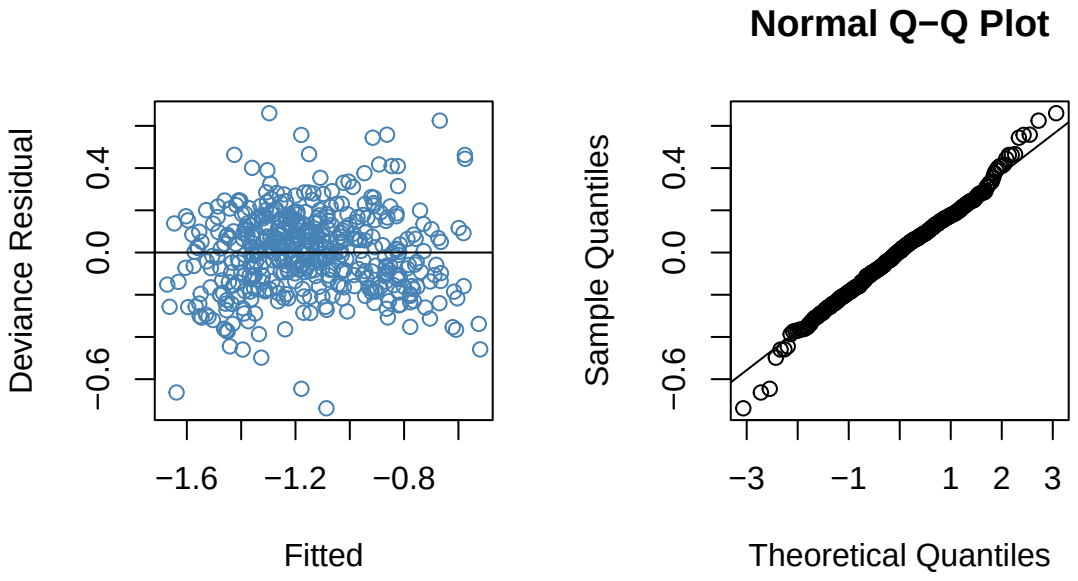
Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Creek 705 (Control)	705-10	2018	8	control	before	-1.8239	-1.0860	-3.711	N
Davidson Creek	DC-15	2023	2	impact	after	-2.3010	-1.6380	-3.334	N
Davidson Creek	DC-15	2023	5	impact	after	-0.6364	-1.2965	3.319	Y
Creek 705 (Control)	705-10	2018	9	control	before	-1.8239	-1.1783	-3.246	N
Creek 705 (Control)	705-05	2025	9	control	after	-0.0438	-0.6686	3.141	Y

Based on examination of the residuals, the log-10 transformed data were selected for analysis. No outliers were removed prior to analysis.

1.4 Before-After Control-Impact Linear Modeling

A models was fit to compare impact sites with control sites.

Plot of Standardized Residuals and Fitted Values



Results of the ANOVA test on the fixed effects of the model:

	Sum Sq.	Mean Sq.	NumDF	DenDF	F value	p	p adjusted
class	0.11603	0.11603	1	4.017	2.934	0.162	
period	0.04718	0.04718	1	44.682	1.193	0.281	
class:period	0.09901	0.09901	1	431.778	2.504	0.114	0.137

Results of the observed power calculation for the between-effect test on the fixed effects for repeated-measures ANOVA analysis at a significance level of 0.05:

Sample Size	Effect Size (f2)	Expected Power	Power Test
462	0.1434	73%	Repeated-Measures ANOVA

Summary of BACI contrasts for relative difference between changes from the *before* to *after* in impact sites (DC-05, DC-10, DC-15, DC-20) and control sites (705-05, 705-10, FC-01), with p value adjusted for multiple comparisons:

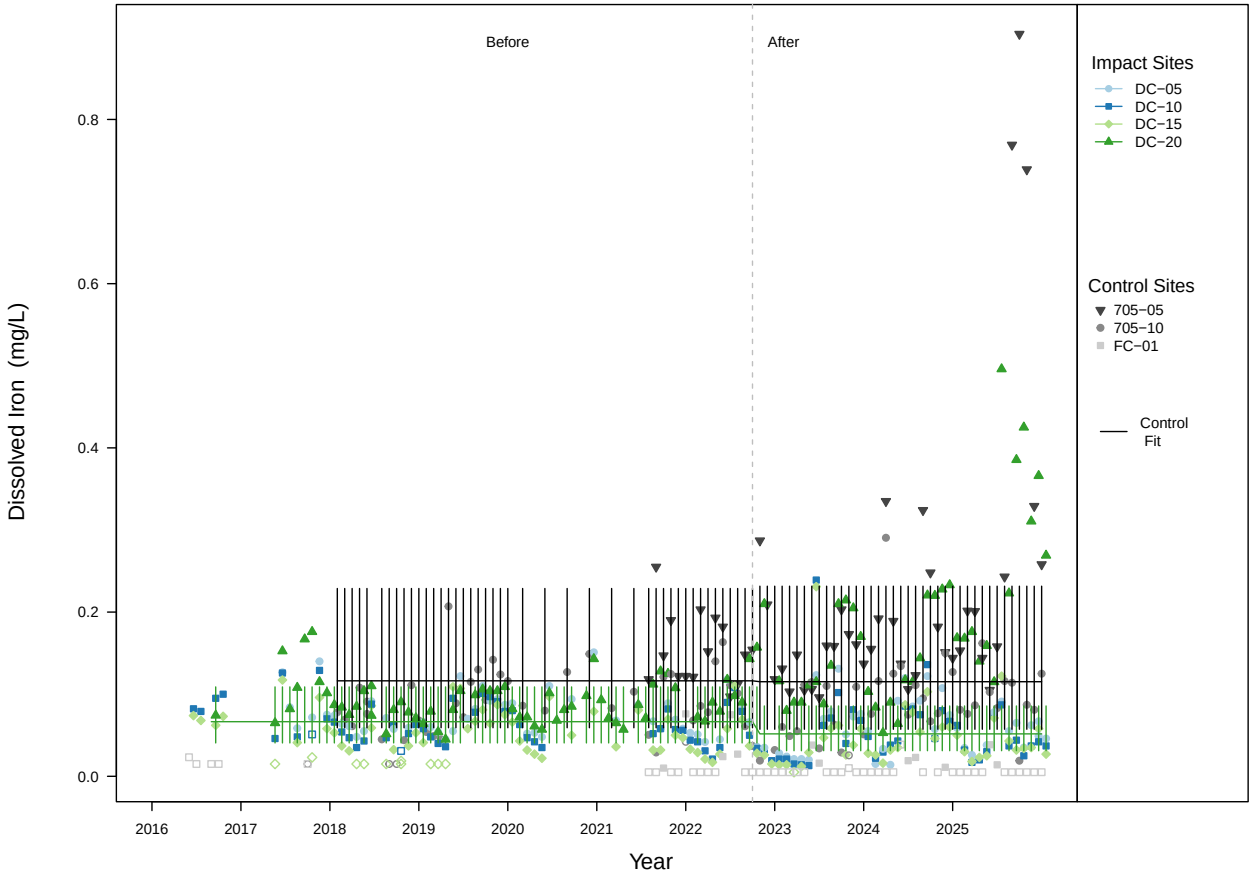
Impact vs.	Estimate	Significance
control sites	-0.1055	not significant

Conclusion:

The change in Dissolved Iron concentrations at the impact sites from *before* to *after* was not significantly (*adjusted p =* 0.137) different from the change at the control sites, according to the test on the BACI term (*class:period*).

1.5 Model Summary

The overall performance of the model is shown in the plot below. All the observations are plotted along with the model estimates. The model fitted values and 95% confidence intervals are indicated as lines and errors.



Note: Open symbols represent cases where the results were below the sample detection limit. Model fitted values are based on site class and period. Error bars indicate 95% confidence intervals. The positions of data along the x-axis are adjusted for legibility. Modelled log-transformed values were converted back to natural scale.

Final Summary Table

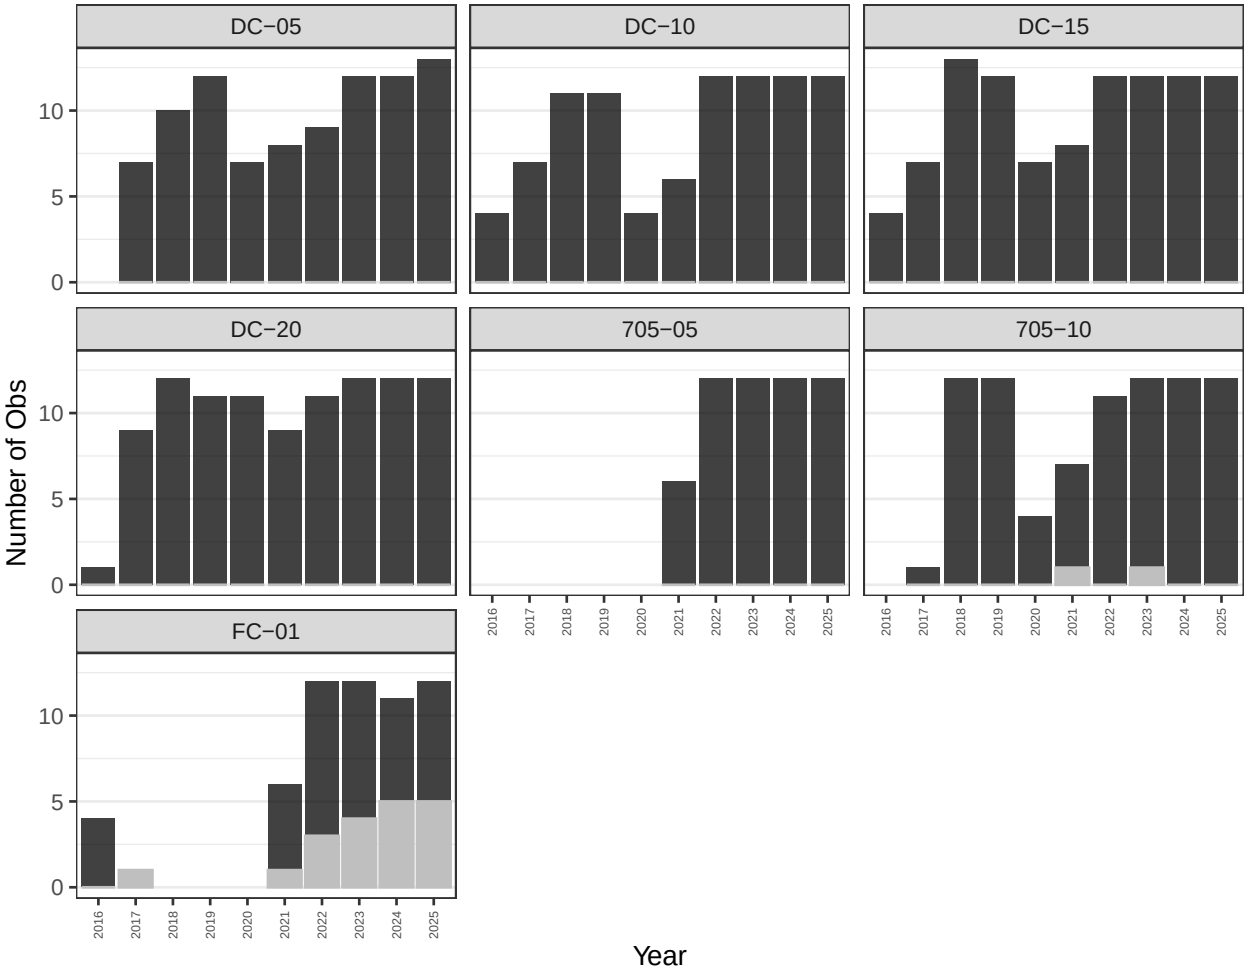
Variable	Dissolved Iron
Watershed	Davidson Creek
Waterbody	Stream
Streams Removed	FC-01
Data Transformation	Log-10 transformed
Model Type	Linear Mixed Effects Regression
Is BACI significant	No

A-12.1.34 Dissolved Manganese

1 Davidson Creek

1.1 Censored Data

The following charts indicate the number of measurements taken in each year from each stream that were below the detection limit (light gray) or above the detection limit (dark gray).



Observations at or below the analytical detection limit were considered censored. Data were excluded from the analysis if greater than 70% of observations from a site were censored or if greater than 50% of observations in a site's sampling year were censored. If more than 10% of observations from a site in a sampling year were censored, data were flagged to caution interpretation of results. The following observations were excluded:

Watershed	Site	Year	Class	Period	#Obs Removed
Fawnie Creek (Control)	FC-01	2017	control	before	1

1.2 Sample Sizes for Modelling

The remaining sample sizes per site and period are summarised in the table below.

Watershed	Site	Period	N	Median	% Censored
Davidson Creek	DC-05	before	51	0.0024	0.000
Davidson Creek	DC-05	after	39	0.0039	0.000
Davidson Creek	DC-10	before	52	0.0021	0.000
Davidson Creek	DC-10	after	39	0.0028	0.000
Davidson Creek	DC-15	before	60	0.0032	0.000
Davidson Creek	DC-15	after	39	0.0031	0.000

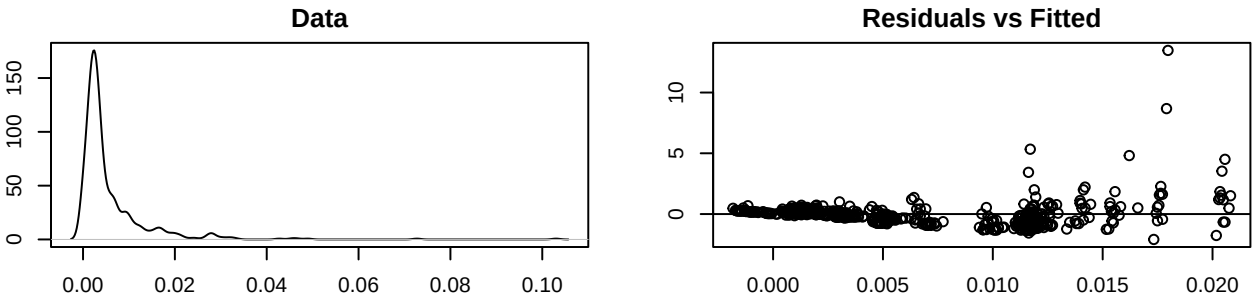
Creek 705 (Control)	705-10	before	45	0.0020	2.222
Creek 705 (Control)	705-10	after	38	0.0019	2.632
Fawnie Creek (Control)	FC-01	before	19	0.0002	15.790
Fawnie Creek (Control)	FC-01	after	38	0.0001	39.474

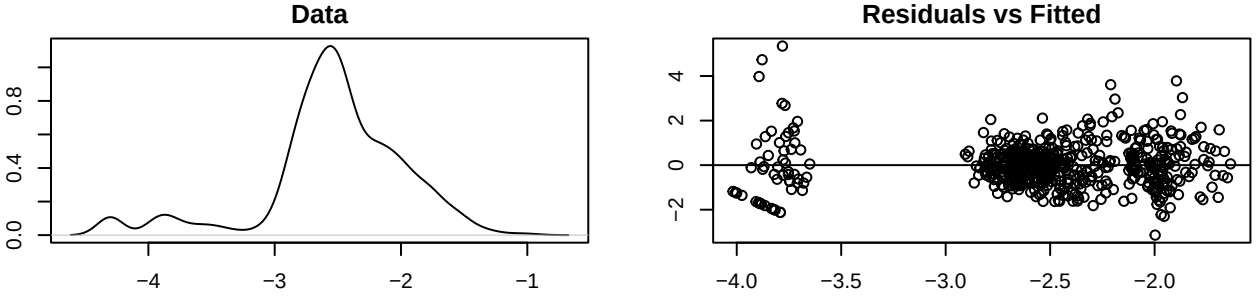
1.3 Initial Model Fit

Initially a model was fit to all sites to assess the need for transformations.

Natural Scale Model



Log−10 Transformed Model



Outliers

The following is a summary of outliers identified (if any) using preliminary regression models. All data points were plotted in the summary figures. The analysis needs to be interpreted with care and in conjunction with graphical displays if large outliers are present.

Outliers on natural scale:

Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Creek 705 (Control)	705-05	2025	10	control	after	0.1030	0.0180	13.467	Y
Creek 705 (Control)	705-05	2025	8	control	after	0.0727	0.0179	8.679	Y
Davidson Creek	DC-05	2025	9	impact	after	0.0454	0.0117	5.337	Y
Davidson Creek	DC-20	2022	12	impact	after	0.0466	0.0162	4.813	Y
Davidson Creek	DC-20	2025	11	impact	after	0.0490	0.0206	4.503	Y
Davidson Creek	DC-20	2025	12	impact	after	0.0427	0.0204	3.527	Y
Davidson Creek	DC-05	2025	7	impact	after	0.0333	0.0116	3.433	Y

Outliers on log scale:

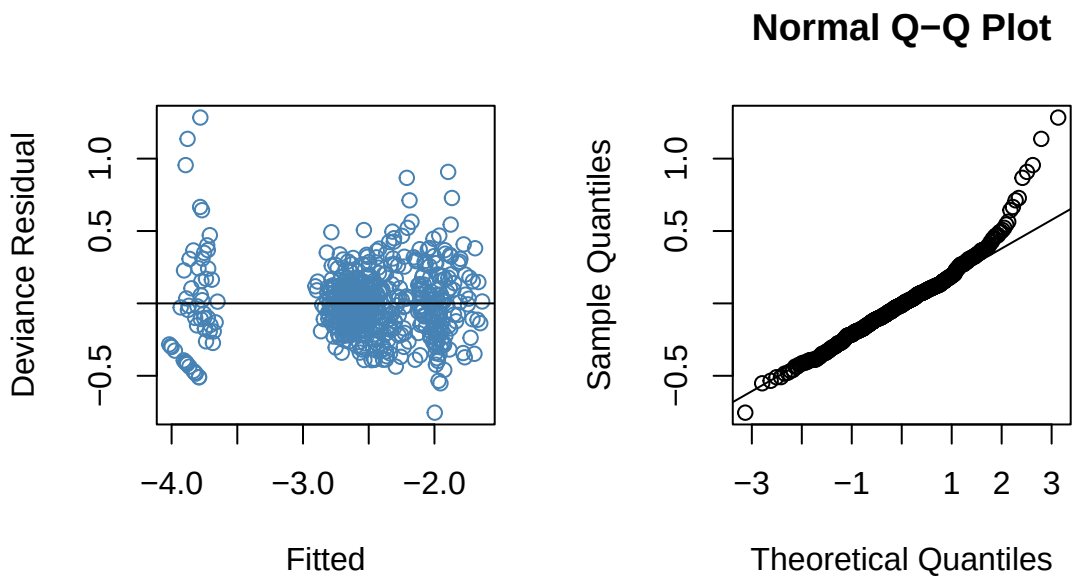
Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Fawnie Creek (Control)	FC-01	2022	6	control	before	-2.4976	-3.781	5.345	Y
Fawnie Creek (Control)	FC-01	2021	12	control	before	-2.7423	-3.879	4.731	Y
Fawnie Creek (Control)	FC-01	2023	5	control	after	-2.9378	-3.893	3.977	Y
Creek 705 (Control)	705-05	2025	10	control	after	-0.9872	-1.895	3.782	Y
Davidson Creek	DC-05	2025	9	impact	after	-1.3429	-2.210	3.611	Y
Creek 705 (Control)	705-05	2022	6	control	before	-2.7520	-1.997	-3.142	Y
Creek 705 (Control)	705-05	2025	8	control	after	-1.1385	-1.867	3.031	Y

Based on examination of the residuals, the log-10 transformed data were selected for analysis. No outliers were removed prior to analysis.

1.4 Before-After Control-Impact Linear Modeling

A models was fit to compare impact sites with control sites.

Plot of Standardized Residuals and Fitted Values



Results of the ANOVA test on the fixed effects of the model:

	Sum Sq.	Mean Sq.	NumDF	DenDF	F value	p	p adjusted
class	0.0669	0.0669	1	5.003	1.159	0.331	
period	0.1242	0.1242	1	18.812	2.153	0.159	
class:period	1.1911	1.1911	1	554.318	20.644	<0.001	2.09e-05

Results of the observed power calculation for the between-effect test on the fixed effects for repeated-measures ANOVA analysis at a significance level of 0.05:

Sample Size	Effect Size (f2)	Expected Power	Power Test
574	0.1335	77%	Repeated-Measures ANOVA

Summary of BACI contrasts for relative difference between changes from the *before* to *after* in impact sites (DC-05, DC-10, DC-15, DC-20) and control sites (705-05, 705-10, FC-01), with p value adjusted for multiple comparisons:

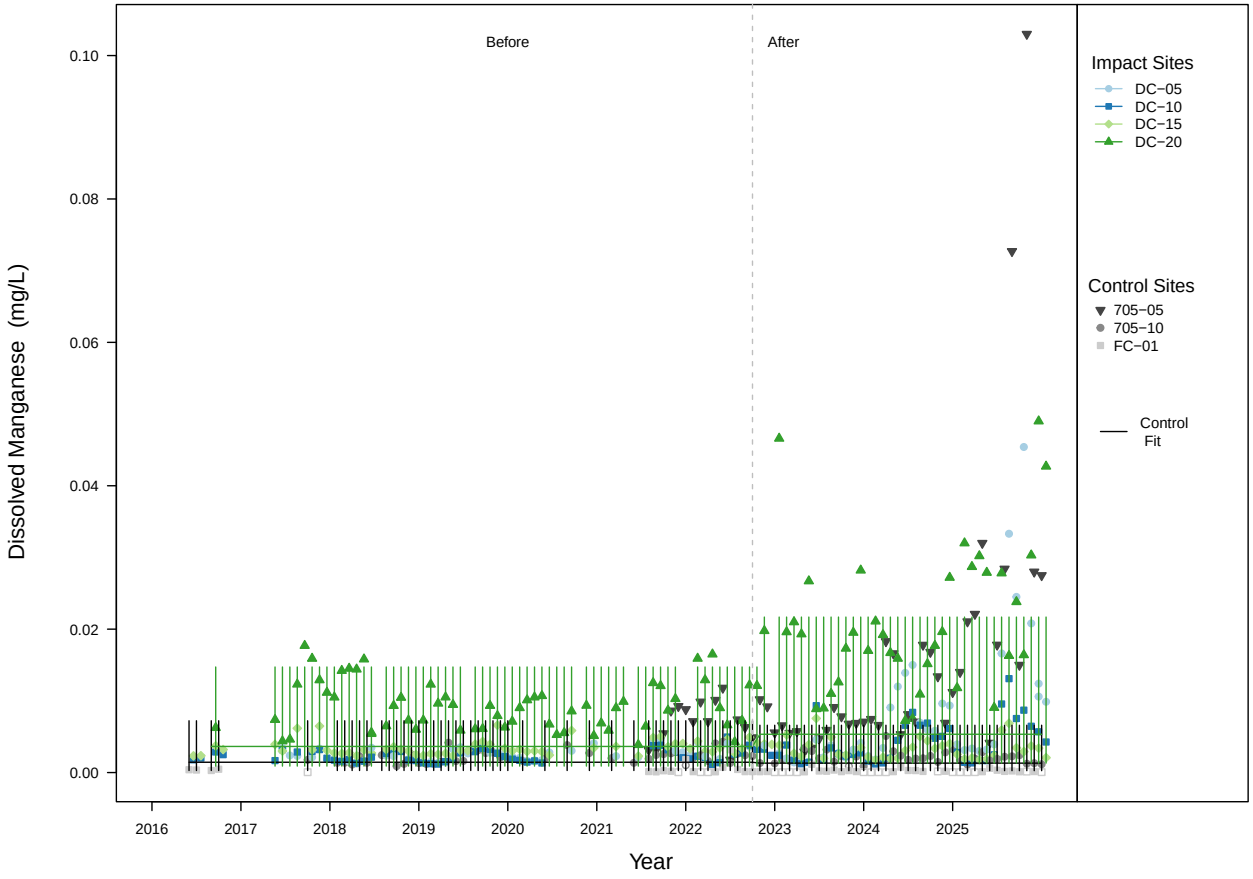
Impact vs.	Estimate	Significance
control sites	0.2057	significant

Conclusion:

The change in Dissolved Manganese concentrations at the impact sites from *before* to *after* was significantly (*adjusted p* = 2.09×10^{-5}) different from the change at the control sites, according to the test on the BACI term (*class:period*).

1.5 Model Summary

The overall performance of the model is shown in the plot below. All the observations are plotted along with the model estimates. The model fitted values and 95% confidence intervals are indicated as lines and errors.



Note: Open symbols represent cases where the results were below the sample detection limit. Model fitted values are based on site class and period. Error bars indicate 95% confidence intervals. The positions of data along the x-axis are adjusted for legibility. Modelled log-transformed values were converted back to natural scale.

Final Summary Table

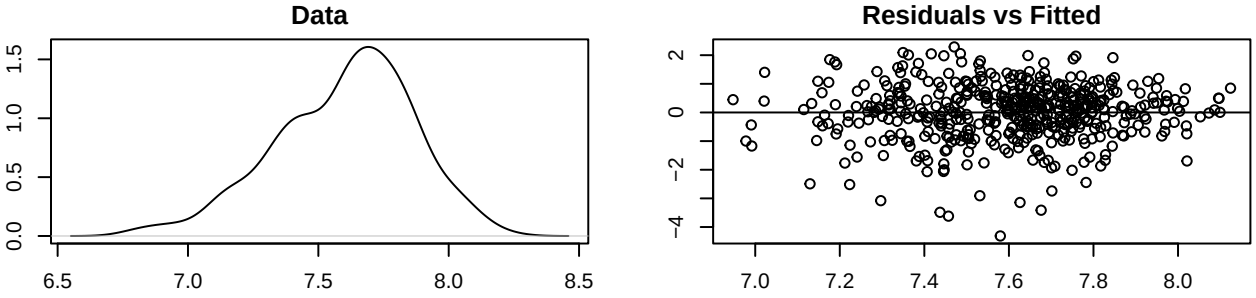
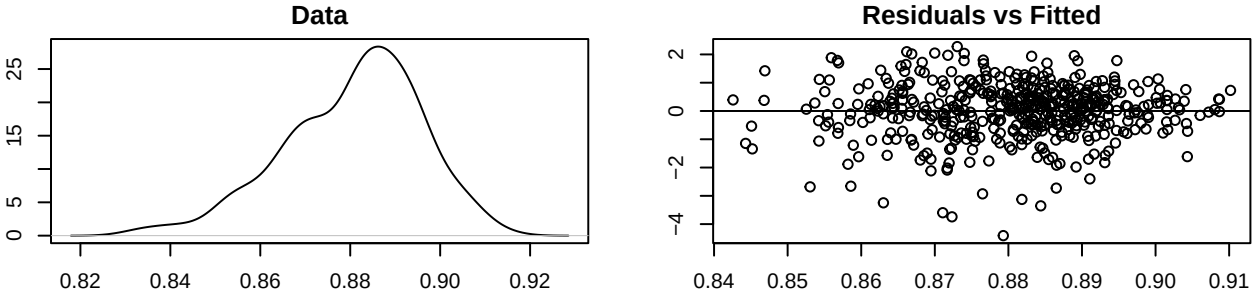
1.3 Initial Model Fit

Initially a model was fit to all sites to assess the need for transformations.

Natural Scale Model



Log−10 Transformed Model



Outliers

The following is a summary of outliers identified (if any) using preliminary regression models. All data points were plotted in the summary figures. The analysis needs to be interpreted with care and in conjunction with graphical displays if large outliers are present.

Outliers on natural scale:

Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Fawnie Creek (Control)	FC-01	2023	7	control	after	6.94	7.580	-4.312	Y
Creek 705 (Control)	705-10	2023	7	control	after	6.92	7.457	-3.620	Y
Creek 661	661-10	2024	6	impact	after	6.92	7.437	-3.485	Y
Creek 661	661-20	2022	6	impact	before	7.17	7.676	-3.412	Y
Creek 661	661-05	2024	6	impact	after	7.16	7.626	-3.143	Y
Creek 705 (Control)	705-05	2023	7	control	after	6.84	7.297	-3.080	Y

Outliers on log scale:

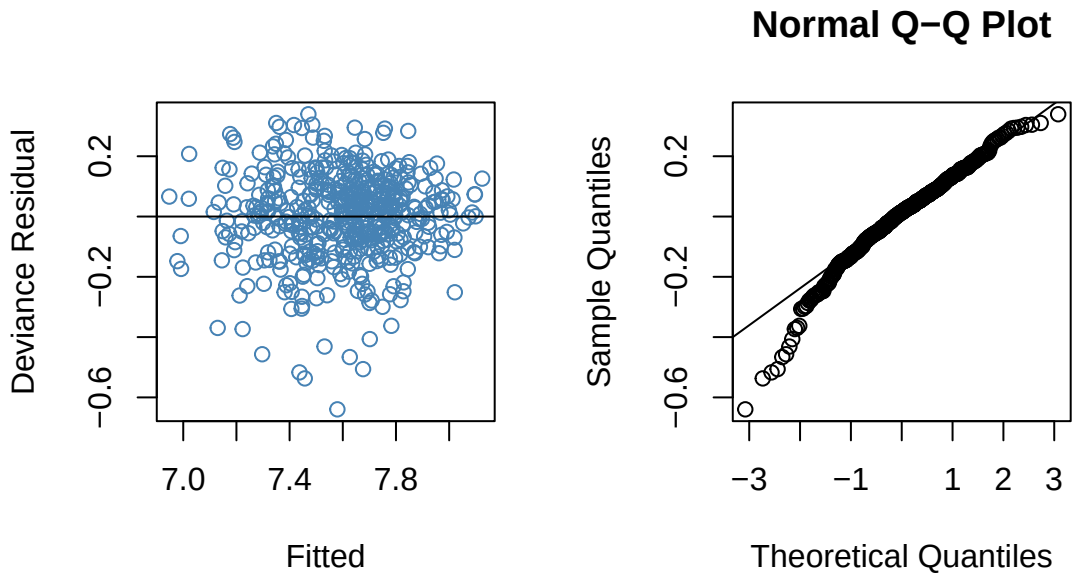
Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Fawnie Creek (Control)	FC-01	2023	7	control	after	0.8414	0.8793	-4.407	Y
Creek 705 (Control)	705-10	2023	7	control	after	0.8401	0.8723	-3.743	Y
Creek 661	661-10	2024	6	impact	after	0.8401	0.8711	-3.597	Y
Creek 661	661-20	2022	6	impact	before	0.8555	0.8844	-3.354	Y
Creek 705 (Control)	705-05	2023	7	control	after	0.8351	0.8630	-3.247	Y
Creek 661	661-05	2024	6	impact	after	0.8549	0.8818	-3.126	Y

Based on examination of the residuals, the untransformed data were selected for analysis. No outliers were removed prior to analysis.

1.4 Before-After Control-Impact Linear Modeling

A models was fit to compare impact sites with control sites.

Plot of Standardized Residuals and Fitted Values



Results of the ANOVA test on the fixed effects of the model:

	Sum Sq.	Mean Sq.	NumDF	DenDF	F value	p	p adjusted
class	0.1176	0.1176	1	7.024	5.343	0.0540	
period	0.2050	0.2050	1	30.555	9.316	0.0047	
class:period	0.2357	0.2357	1	457.083	10.707	0.0012	0.00206

Results of the observed power calculation for the between-effect test on the fixed effects for repeated-measures ANOVA analysis at a significance level of 0.05:

Sample Size	Effect Size (f2)	Expected Power	Power Test
479	0.3312	100%	Repeated-Measures ANOVA

Summary of BACI contrasts for relative difference between changes from the *before* to *after* in impact sites (661-03, 661-04, 661-05, 661-10, 661-20) and control sites (661-01, 705-05, 705-10, FC-01), with p value adjusted for multiple comparisons:

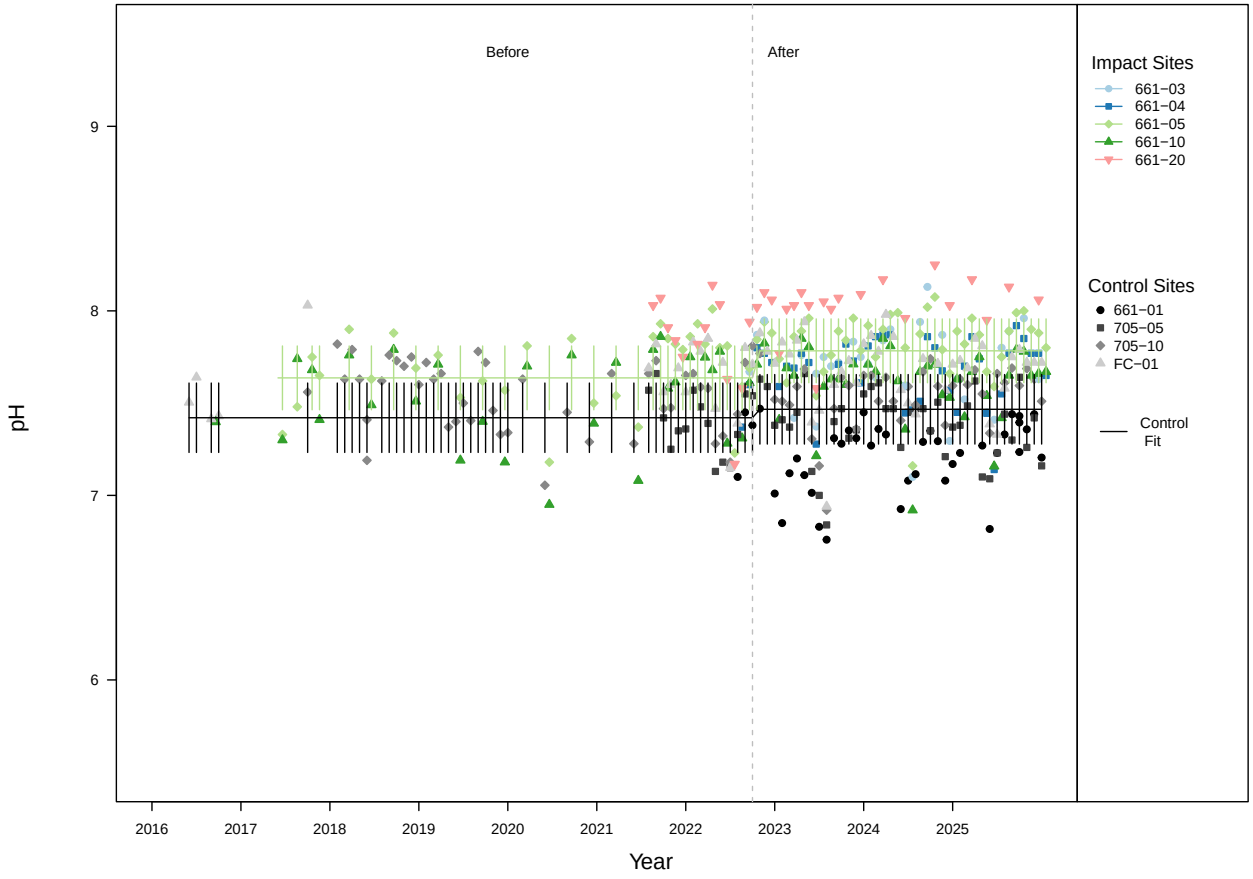
Impact vs.	Estimate	Significance
control sites	0.1008	significant

Conclusion:

The change in pH at the impact sites from *before* to *after* was significantly (*adjusted p =* 0.0021) different from the change at the control sites, according to the test on the BACI term (*class:period*).

1.5 Model Summary

The overall performance of the model is shown in the plot below. All the observations are plotted along with the model estimates. The model fitted values and 95% confidence intervals are indicated as lines and errors.



Note: Model fitted values are based on site class and period. Error bars indicate 95% confidence intervals. The positions of data along the x-axis are adjusted for legibility.

Final Summary Table

Variable	pH
Watershed	Creek 661

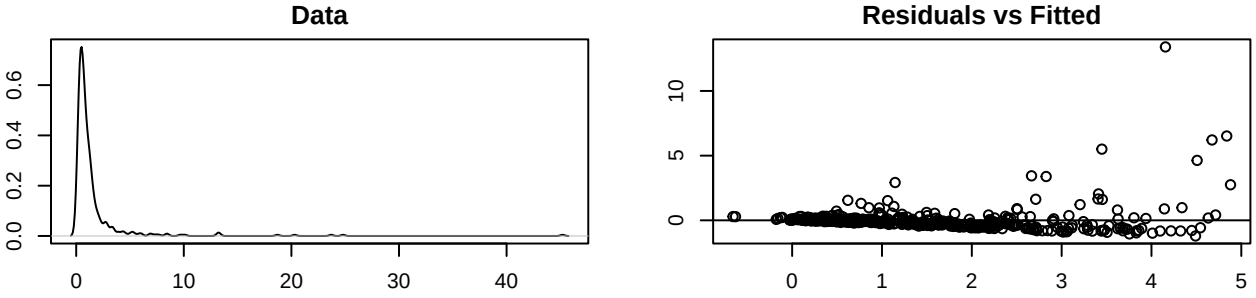
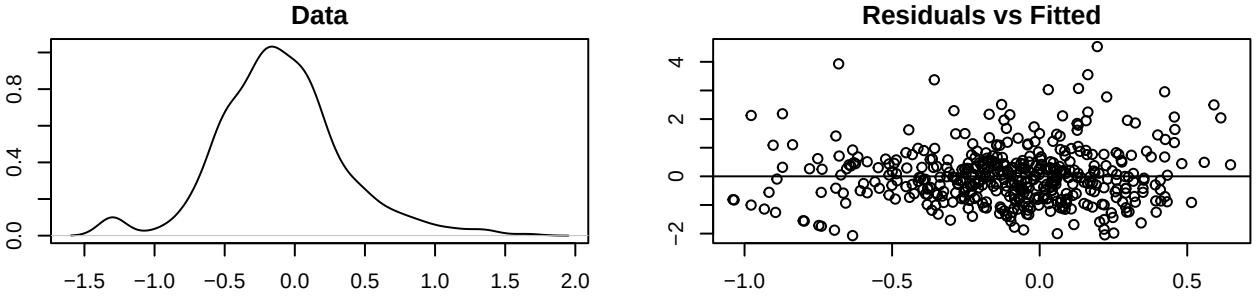
1.3 Initial Model Fit

Initially a model was fit to all sites to assess the need for transformations.

Natural Scale Model



Log−10 Transformed Model



Outliers

The following is a summary of outliers identified (if any) using preliminary regression models. All data points were plotted in the summary figures. The analysis needs to be interpreted with care and in conjunction with graphical displays if large outliers are present.

Outliers on natural scale:

Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Creek 661	661-05	2023	11	impact	after	45.2	4.156	13.400	Y
Creek 661	661-05	2025	4	impact	after	24.8	4.838	6.517	Y
Creek 661	661-05	2024	3	impact	after	23.7	4.674	6.212	Y
Creek 661	661-04	2025	3	impact	after	20.3	3.448	5.502	Y
Creek 661	661-05	2024	5	impact	after	18.7	4.508	4.633	Y
Creek 661	661-04	2025	7	impact	after	13.2	2.665	3.440	Y
Creek 661	661-20	2023	5	impact	after	13.2	2.828	3.386	Y

Outliers on log scale:

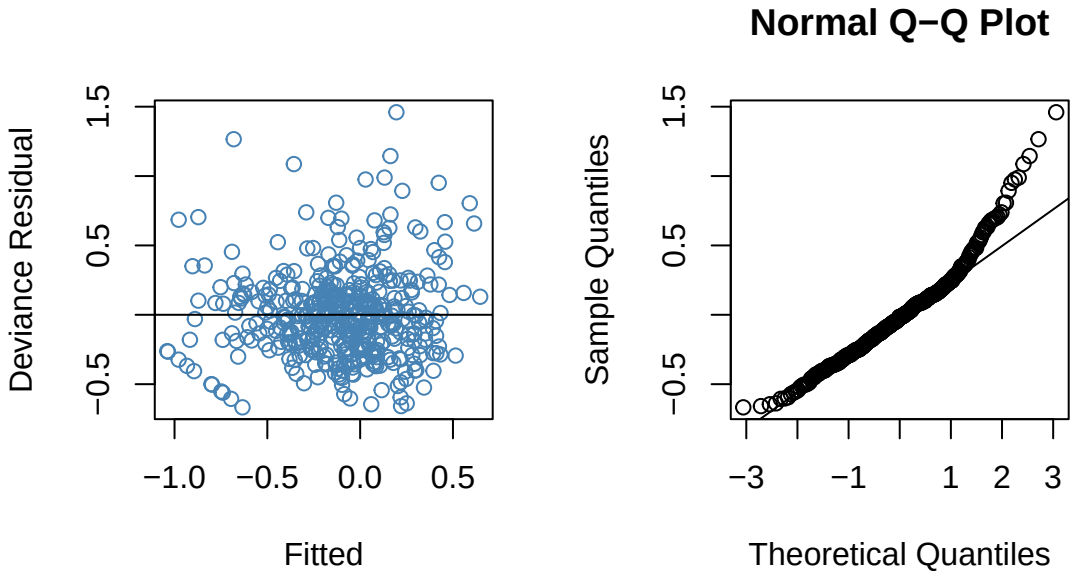
Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Creek 661	661-05	2023	11	impact	after	1.6551	0.1952	4.532	Y
Fawnie Creek (Control)	FC-01	2023	5	control	after	0.5846	-0.6811	3.929	Y
Creek 661	661-04	2025	3	impact	after	1.3075	0.1632	3.552	Y
Creek 705 (Control)	705-10	2023	7	control	after	0.7292	-0.3570	3.372	Y
Creek 661	661-04	2025	7	impact	after	1.1206	0.1316	3.070	Y
Creek 705 (Control)	705-05	2025	12	control	after	1.0043	0.0292	3.027	Y

Based on examination of the residuals, the log-10 transformed data were selected for analysis. No outliers were removed prior to analysis.

1.4 Before-After Control-Impact Linear Modeling

A models was fit to compare impact sites with control sites.

Plot of Standardized Residuals and Fitted Values



Results of the ANOVA test on the fixed effects of the model:

	Sum Sq.	Mean Sq.	NumDF	DenDF	F value	p	p adjusted
class	0.46771	0.46771	1	7.097	4.5072	0.0709	
period	0.02566	0.02566	1	22.948	0.2472	0.624	
class:period	1.22678	1.22678	1	432.370	11.8222	<0.001	0.00131

Results of the observed power calculation for the between-effect test on the fixed effects for repeated-measures ANOVA analysis at a significance level of 0.05:

Sample Size	Effect Size (f2)	Expected Power	Power Test
450	0.2334	99%	Repeated-Measures ANOVA

Summary of BACI contrasts for relative difference between changes from the *before* to *after* in impact sites (661-03, 661-04, 661-05, 661-10, 661-20) and control sites (661-01, 705-05, 705-10, FC-01), with p value adjusted for multiple comparisons:

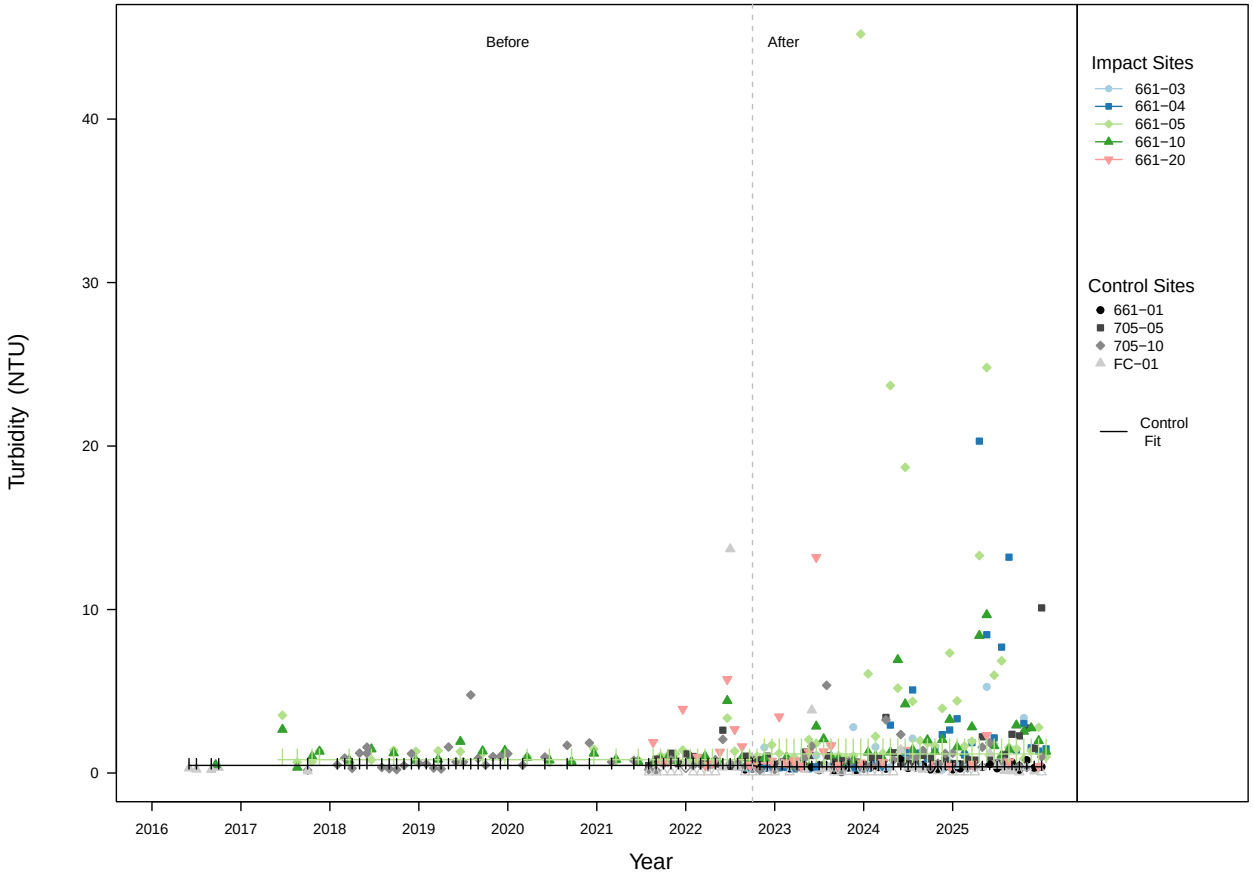
Impact vs.	Estimate	Significance
control sites	0.2435	significant

Conclusion:

The change in Turbidity concentrations at the impact sites from *before* to *after* was significantly (*adjusted p* = 0.0013) different from the change at the control sites, according to the test on the BACI term (*class:period*).

1.5 Model Summary

The overall performance of the model is shown in the plot below. All the observations are plotted along with the model estimates. The model fitted values and 95% confidence intervals are indicated as lines and errors.



Note: Open symbols represent cases where the results were below the sample detection limit. Model fitted values are based on site class and period. Error bars indicate 95% confidence intervals. The positions of data along the x-axis are adjusted for legibility. Modelled log-transformed values were converted back to natural scale.

Final Summary Table

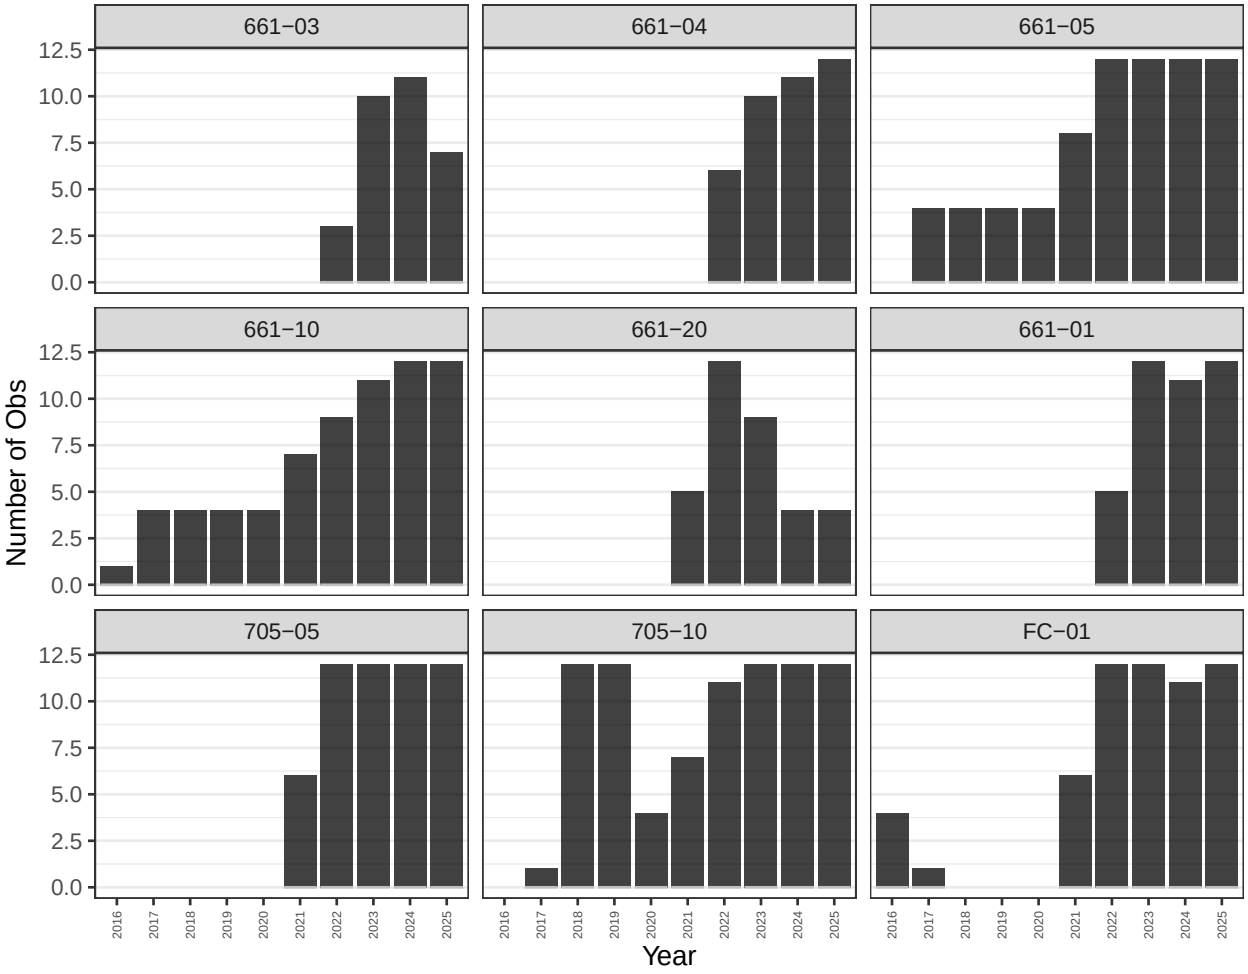
Variable	Turbidity
Watershed	Creek 661
Waterbody	Stream
Streams Removed	None
Data Transformation	Log-10 transformed
Model Type	Linear Mixed Effects Regression
Is BACI significant	Yes

A-12.2.4 Total Dissolved Solids

1 Creek 661

1.1 Censored Data

The following charts indicate the number of measurements taken in each year from each stream that were below the detection limit (light gray) or above the detection limit (dark gray).



Observations at or below the analytical detection limit were considered censored. Data were excluded from the analysis if greater than 70% of observations from a site were censored or if greater than 50% of observations in a site's sampling year were censored. If more than 10% of observations from a site in a sampling year were censored, data were flagged to caution interpretation of results. The following observations were excluded:

None

1.2 Sample Sizes for Modelling

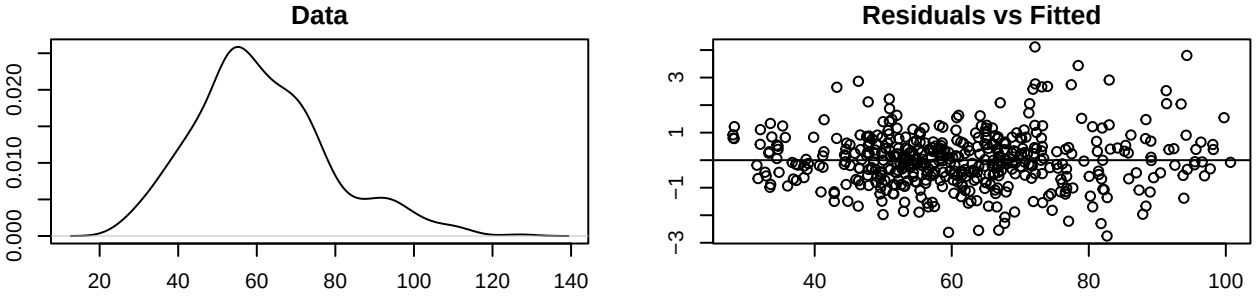
The remaining sample sizes per site and period are summarised in the table below.

Watershed	Site	Period	N	Median	% Censored
Creek 661	661-03	before	2	89.50	0
Creek 661	661-03	after	29	80.00	0
Creek 661	661-04	before	3	56.00	0
Creek 661	661-04	after	36	66.00	0
Creek 661	661-05	before	33	68.00	0
Creek 661	661-05	after	39	73.00	0
Creek 661	661-10	before	31	59.00	0
Creek 661	661-10	after	37	68.00	0
Creek 661	661-20	before	14	85.25	0
Creek 661	661-20	after	20	95.50	0
Creek 661	661-01	before	3	39.00	0
Creek 661	661-01	after	37	36.00	0
Creek 705 (Control)	705-05	before	15	50.00	0
Creek 705 (Control)	705-05	after	39	48.00	0
Creek 705 (Control)	705-10	before	45	56.00	0
Creek 705 (Control)	705-10	after	38	54.00	0
Fawnie Creek (Control)	FC-01	before	20	51.50	0
Fawnie Creek (Control)	FC-01	after	38	53.00	0

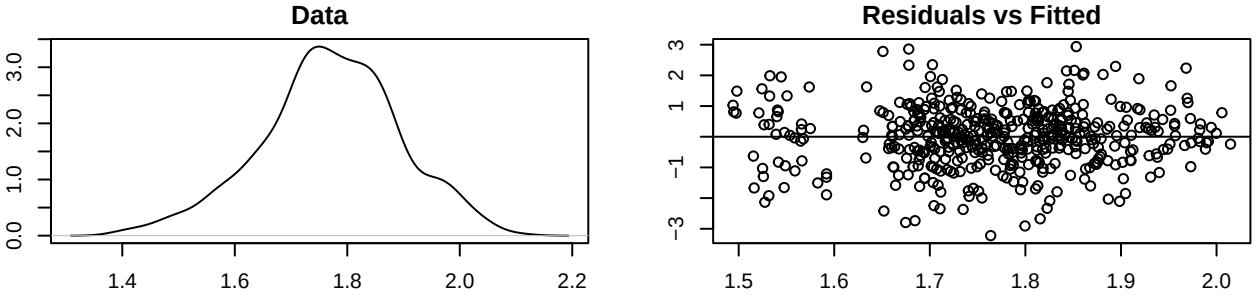
1.3 Initial Model Fit

Initially a model was fit to all sites to assess the need for transformations.

Natural Scale Model



Log−10 Transformed Model



Outliers

The following is a summary of outliers identified (if any) using preliminary regression models. All data points were plotted in the summary figures. The analysis needs to be interpreted with care and in conjunction with graphical displays if large outliers are present.

Outliers on natural scale:

Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Creek 661	661-05	2023	11	impact	after	107.5	72.15	4.113	Y
Creek 661	661-20	2023	7	impact	after	127.0	94.31	3.804	Y
Creek 661	661-05	2025	4	impact	after	108.0	78.46	3.437	Y

Outliers on log scale:

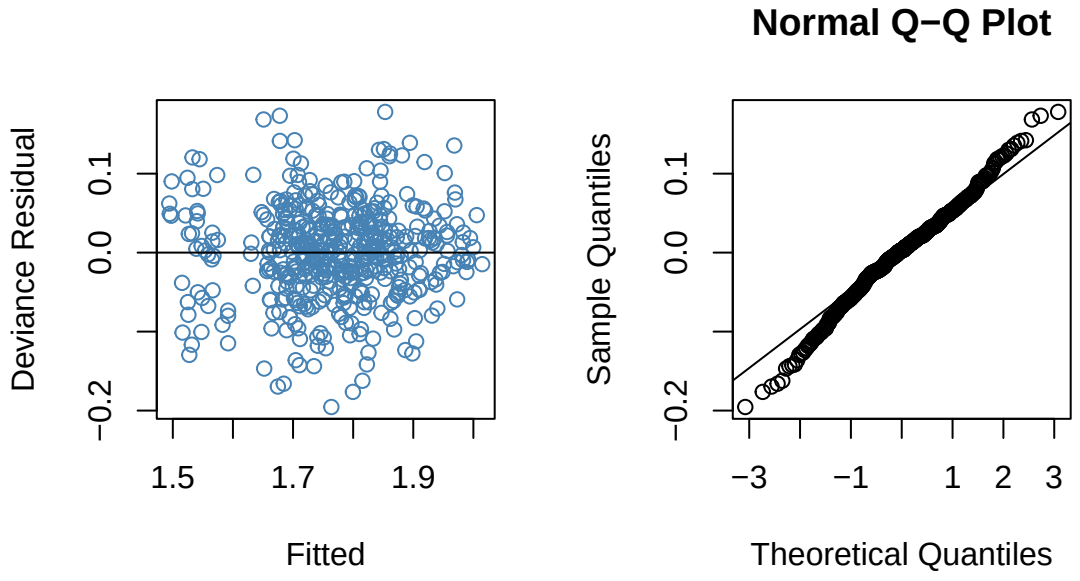
Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Creek 705 (Control)	705-10	2019	8	control	before	1.568	1.764	-3.223	Y

Based on examination of the residuals, the log-10 transformed data were selected for analysis. No outliers were removed prior to analysis.

1.4 Before-After Control-Impact Linear Modeling

A models was fit to compare impact sites with control sites.

Plot of Standardized Residuals and Fitted Values



Results of the ANOVA test on the fixed effects of the model:

	Sum Sq.	Mean Sq.	NumDF	DenDF	F value	p	p adjusted
class	0.048216	0.048216	1	7.019	13.107	0.00846	
period	0.009508	0.009508	1	23.669	2.585	0.121	
class:period	0.068360	0.068360	1	457.822	18.584	<0.001	5.04e-05

Results of the observed power calculation for the between-effect test on the fixed effects for repeated-measures ANOVA analysis at a significance level of 0.05:

Sample Size	Effect Size (f2)	Expected Power	Power Test
479	0.9596	100%	Repeated-Measures ANOVA

Summary of BACI contrasts for relative difference between changes from the *before* to *after* in impact sites (661-03, 661-04, 661-05, 661-10, 661-20) and control sites (661-01, 705-05, 705-10, FC-01), with p value adjusted for multiple comparisons:

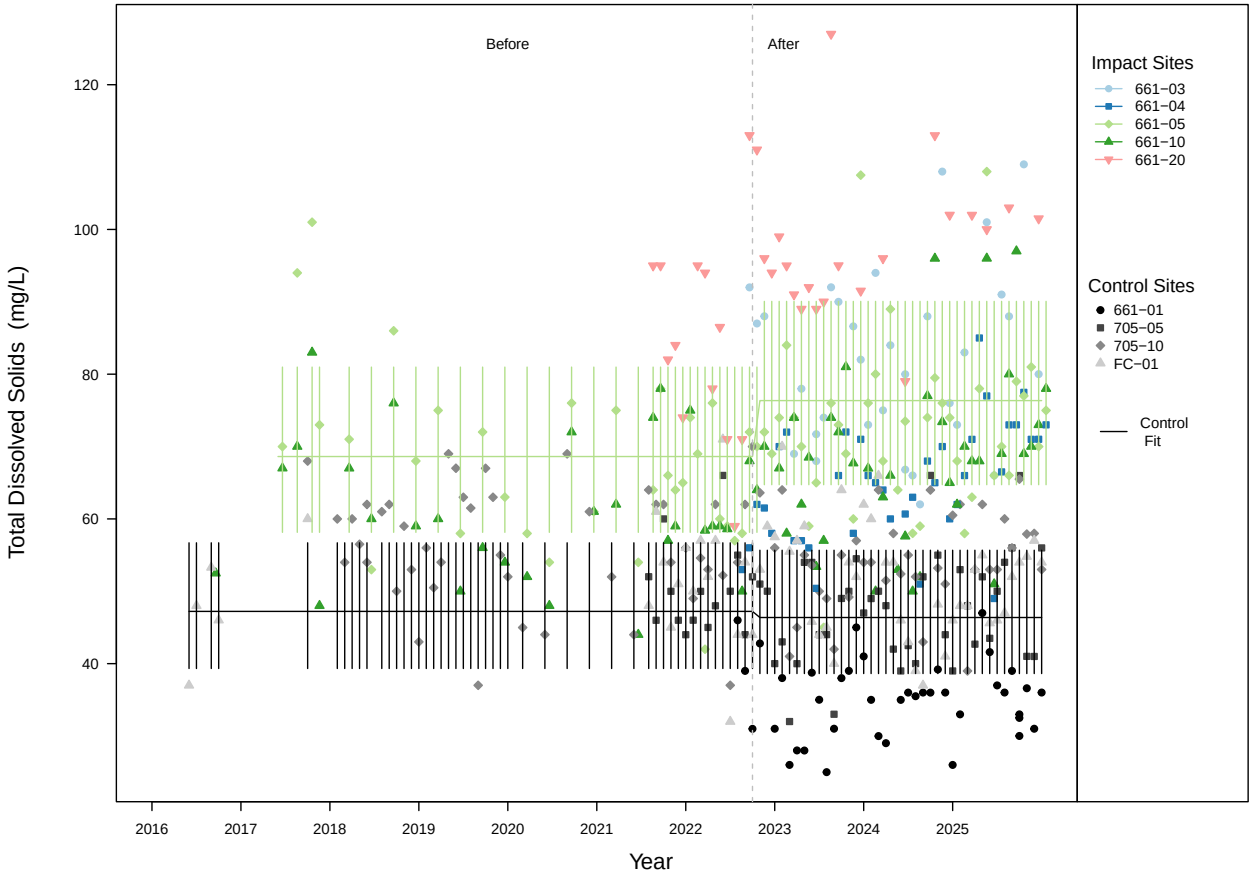
Impact vs.	Estimate	Significance
control sites	0.0542	significant

Conclusion:

The change in Total Dissolved Solids concentrations at the impact sites from *before* to *after* was significantly (*adjusted p* = 5.04×10^{-5}) different from the change at the control sites, according to the test on the BACI term (*class*:*period*).

1.5 Model Summary

The overall performance of the model is shown in the plot below. All the observations are plotted along with the model estimates. The model fitted values and 95% confidence intervals are indicated as lines and errors.



Note: Model fitted values are based on site class and period. Error bars indicate 95% confidence intervals. The positions of data along the x-axis are adjusted for legibility. Modelled log-transformed values were converted back to natural scale.

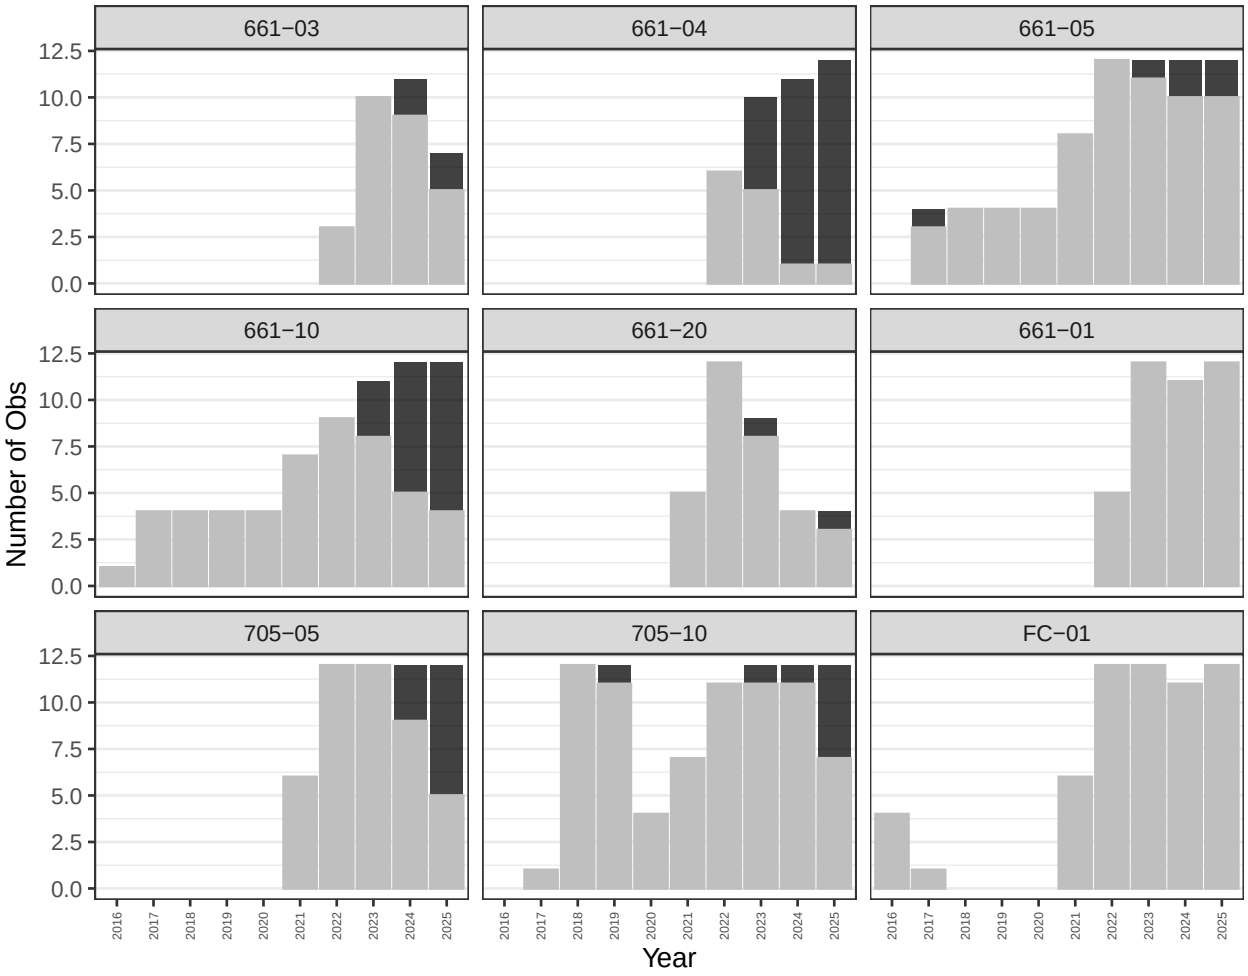
Final Summary Table

Variable	Total Dissolved Solids
Watershed	Creek 661
Waterbody	Stream
Streams Removed	None
Data Transformation	Log-10 transformed
Model Type	Linear Mixed Effects Regression
Is BACI significant	Yes

A-12.2.5 Chloride

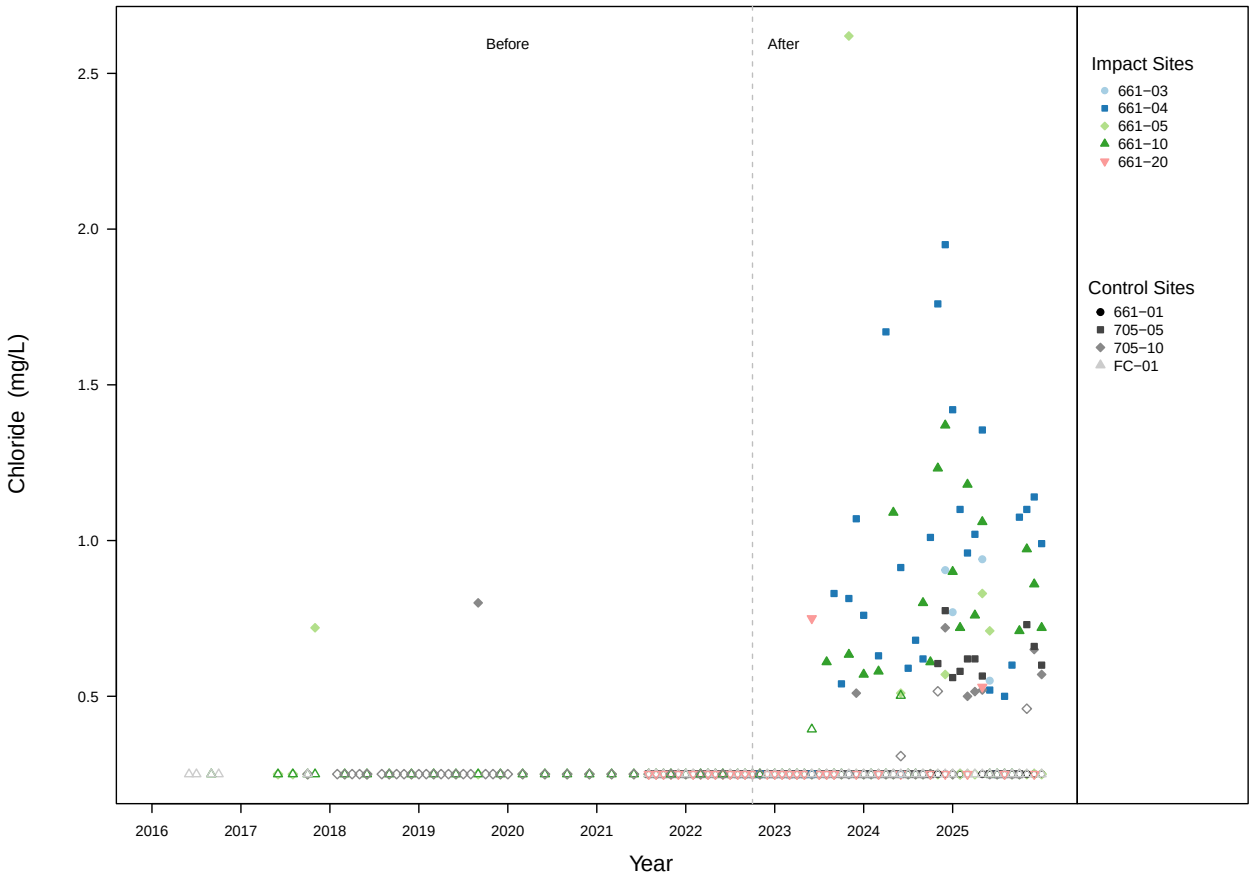
1 Creek 661

1.1 Censored Data The following charts indicate the number of measurements taken in each year from each stream that were below the detection limit (light gray) or above the detection limit (dark gray).



Conclusion:

Statistical analyses were not conducted due to censoring or availability of observations. Below is a summary figure of all observations in the dataset.



Note: Open symbols represent cases where the results were below the sample detection limit.

Final Summary Table

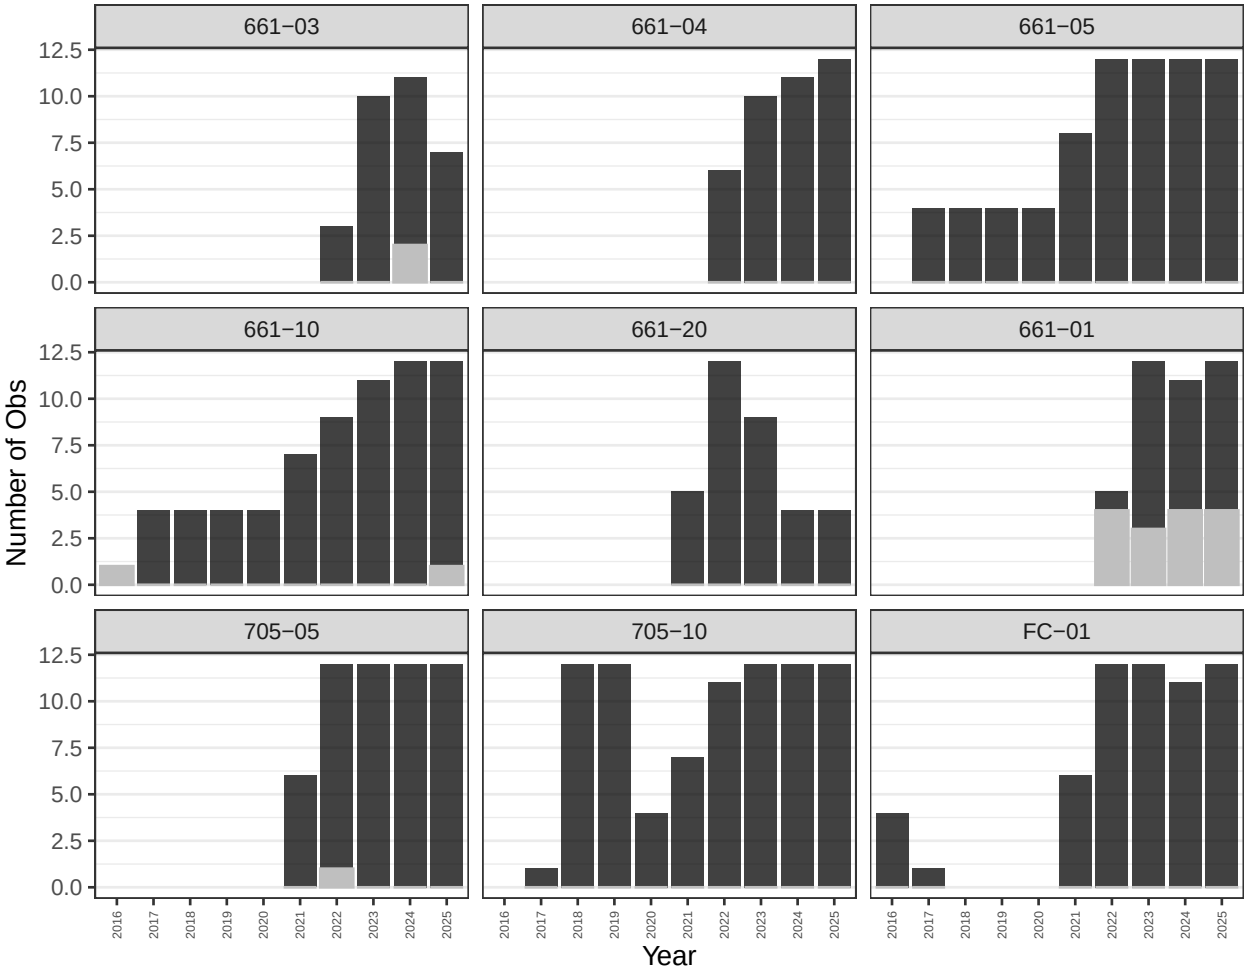
Variable	Chloride
Watershed	Creek 661
Waterbody	Stream
Streams Removed	All Excluded
Data Transformation	N/A
Model Type	N/A
Benchmark	None
Significant BACI term	N/A

A-12.2.6 Sulphate

1 Creek 661

1.1 Censored Data

The following charts indicate the number of measurements taken in each year from each stream that were below the detection limit (light gray) or above the detection limit (dark gray).



Observations at or below the analytical detection limit were considered censored. Data were excluded from the analysis if greater than 70% of observations from a site were censored or if greater than 50% of observations in a site's sampling year were censored. If more than 10% of observations from a site in a sampling year were censored, data were flagged to caution interpretation of results. The following observations were excluded:

Watershed	Site	Year	Class	Period	#Obs Removed
Creek 661	661-10	2016	impact	before	1
Creek 661	661-01	2022	control	before	5
Creek 661	661-01	2022	control	after	5

1.2 Sample Sizes for Modelling

The remaining sample sizes per site and period are summarised in the table below.

Watershed	Site	Period	N	Median	% Censored
Creek 661	661-03	before	2	1.030	0.000
Creek 661	661-03	after	29	1.120	6.897

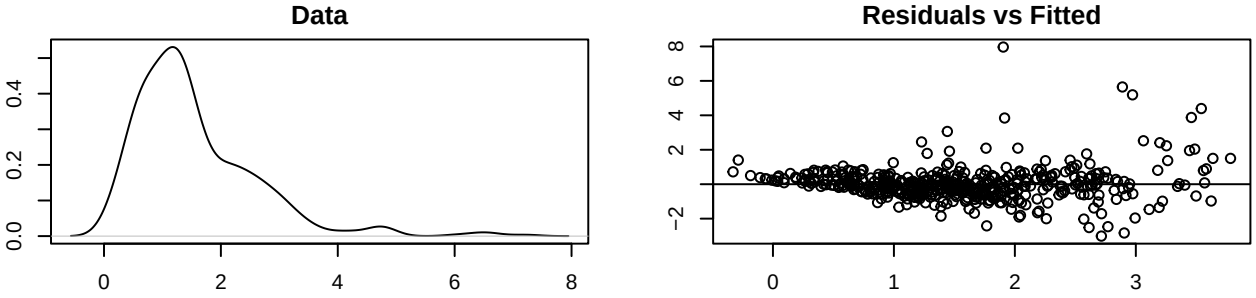
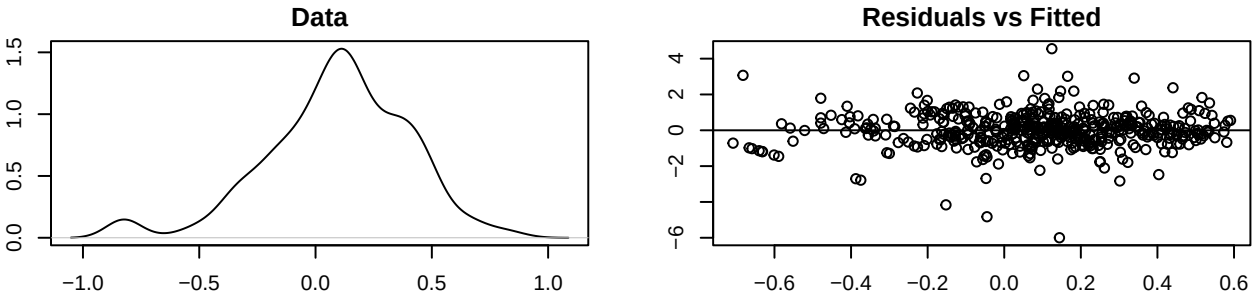
1.3 Initial Model Fit

Initially a model was fit to all sites to assess the need for transformations.

Natural Scale Model



Log−10 Transformed Model



Outliers

The following is a summary of outliers identified (if any) using preliminary regression models. All data points were plotted in the summary figures. The analysis needs to be interpreted with care and in conjunction with graphical displays if large outliers are present.

Outliers on natural scale:

Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Creek 661	661-03	2025	11	impact	after	7.230	1.904	7.964	Y
Creek 661	661-10	2024	4	impact	after	6.665	2.889	5.646	Y
Creek 661	661-04	2024	5	impact	after	6.443	2.973	5.190	Y
Creek 661	661-04	2024	11	impact	after	6.480	3.541	4.394	Y
Creek 661	661-04	2024	12	impact	after	6.050	3.459	3.874	Y
Creek 661	661-03	2024	1	impact	after	4.485	1.915	3.843	Y
Creek 661	661-10	2023	7	impact	after	3.490	1.442	3.063	Y
Creek 661	661-04	2025	8	impact	after	0.700	2.715	-3.013	Y

Outliers on log scale:

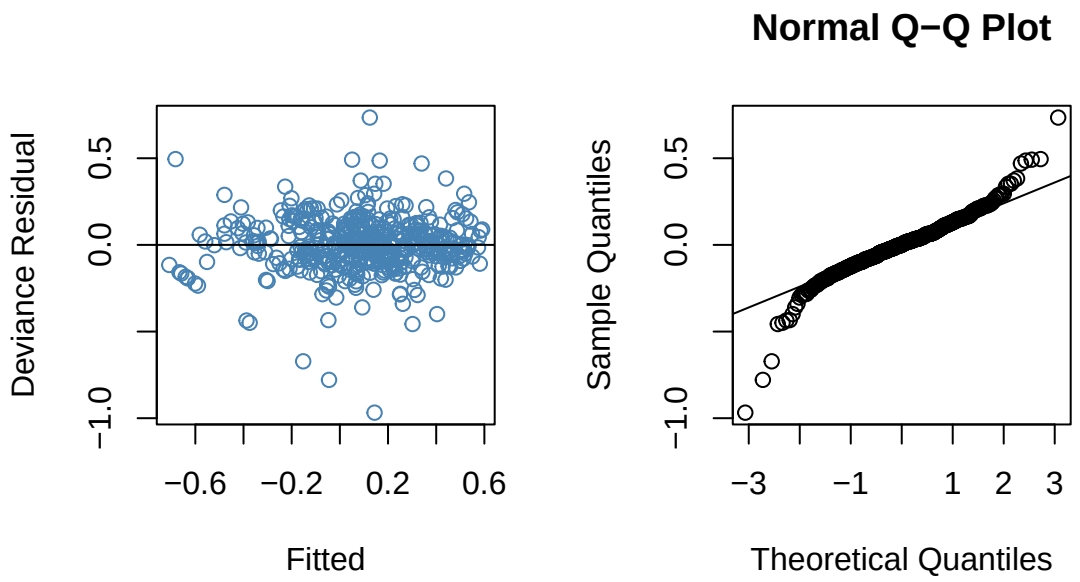
Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Creek 661	661-10	2025	8	impact	after	-0.8239	0.1441	-5.999	N
Creek 661	661-03	2024	5	impact	after	-0.8239	-0.0451	-4.827	N
Creek 661	661-03	2025	11	impact	after	0.8591	0.1243	4.554	Y
Creek 661	661-03	2024	6	impact	after	-0.8239	-0.1522	-4.163	N
Creek 661	661-01	2023	7	control	after	-0.1871	-0.6822	3.068	Y
Creek 661	661-10	2023	7	impact	after	0.5428	0.0510	3.048	Y
Creek 661	661-03	2024	1	impact	after	0.6518	0.1655	3.014	Y

Based on examination of the residuals, the log-10 transformed data were selected for analysis. No outliers were removed prior to analysis.

1.4 Before-After Control-Impact Linear Modeling

A models was fit to compare impact sites with control sites.

Plot of Standardized Residuals and Fitted Values



Results of the ANOVA test on the fixed effects of the model:

	Sum Sq.	Mean Sq.	NumDF	DenDF	F value	p	p adjusted
class	0.049476	0.049476	1	7.016	1.9001	0.2100	
period	0.268256	0.268256	1	14.877	10.3024	0.0059	
class:period	0.006239	0.006239	1	442.889	0.2396	0.6250	0.64

Results of the observed power calculation for the between-effect test on the fixed effects for repeated-measures ANOVA analysis at a significance level of 0.05:

Sample Size	Effect Size (f2)	Expected Power	Power Test
464	0.1465	76%	Repeated-Measures ANOVA

Summary of BACI contrasts for relative difference between changes from the *before* to *after* in impact sites (661-03, 661-04, 661-05, 661-10, 661-20) and control sites (661-01, 705-05, 705-10, FC-01), with p value adjusted for multiple comparisons:

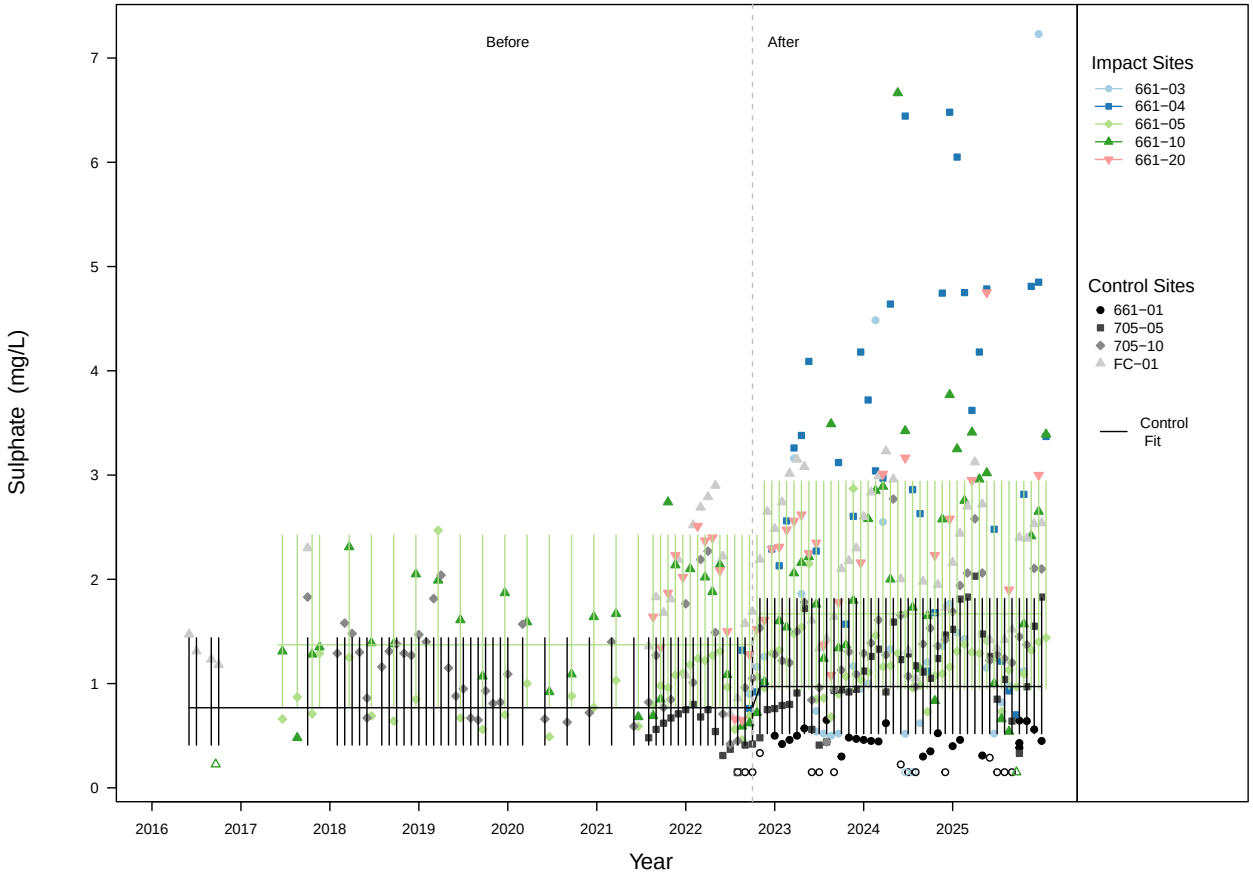
Impact vs.	Estimate	Significance
control sites	-0.0169	not significant

Conclusion:

The change in Sulphate concentrations at the impact sites from *before* to *after* was not significantly (*adjusted p* = 0.64) different from the change at the control sites, according to the test on the BACI term (*class:period*).

1.5 Model Summary

The overall performance of the model is shown in the plot below. All the observations are plotted along with the model estimates. The model fitted values and 95% confidence intervals are indicated as lines and errors.



Note: Open symbols represent cases where the results were below the sample detection limit. Model fitted values are based on site class and period. Error bars indicate 95% confidence intervals. The positions of data along the x-axis are adjusted for legibility. Modelled log-transformed values were converted back to natural scale.

Final Summary Table

Variable	Sulphate
Watershed	Creek 661
Waterbody	Stream
Streams Removed	None
Data Transformation	Log-10 transformed
Model Type	Linear Mixed Effects Regression
Is BACI significant	No

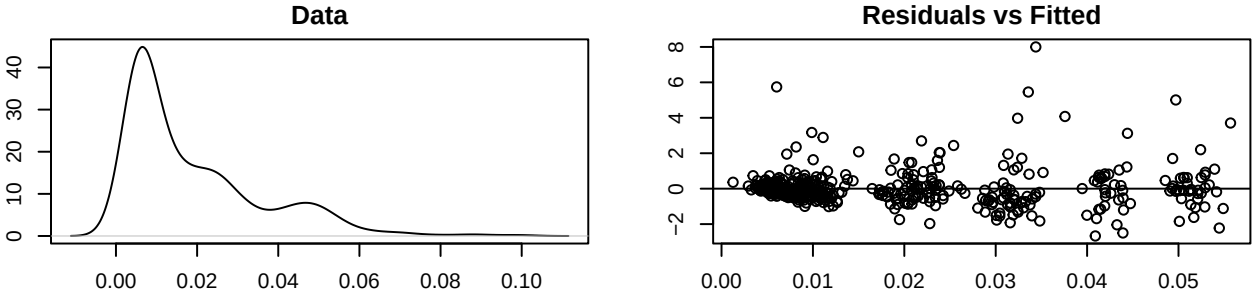
Fawnie Creek (Control)	FC-01	after	37	0.0059	0.000

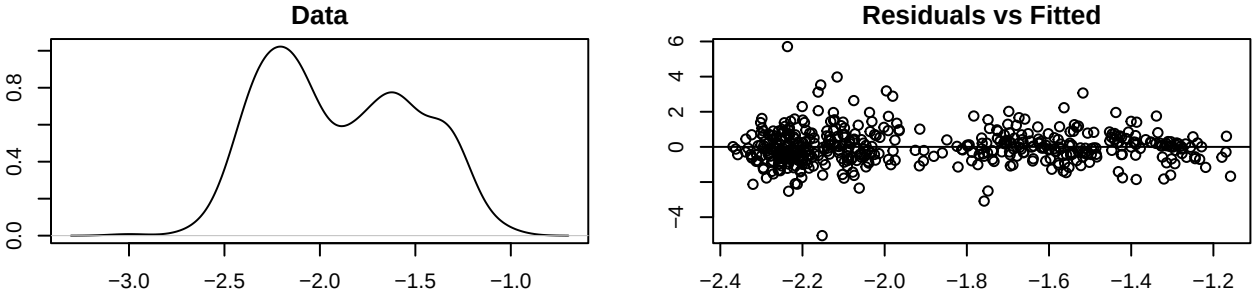
1.3 Initial Model Fit

Initially a model was fit to all sites to assess the need for transformations.

Natural Scale Model



Log−10 Transformed Model



Outliers

The following is a summary of outliers identified (if any) using preliminary regression models. All data points were plotted in the summary figures. The analysis needs to be interpreted with care and in conjunction with graphical displays if large outliers are present.

Outliers on natural scale:

Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Creek 661	661-10	2025	8	impact	after	0.0994	0.0344	8.000	Y
Fawnie Creek (Control)	FC-01	2022	6	control	before	0.0527	0.0060	5.742	Y
Creek 661	661-20	2023	5	impact	after	0.0779	0.0336	5.455	Y
Creek 661	661-05	2023	11	impact	after	0.0904	0.0497	5.007	Y
Creek 661	661-20	2025	4	impact	after	0.0707	0.0376	4.075	Y
Creek 661	661-10	2025	9	impact	after	0.0647	0.0324	3.975	Y
Creek 661	661-05	2025	4	impact	after	0.0858	0.0557	3.705	Y
Creek 661	661-03	2024	1	impact	after	0.0356	0.0099	3.171	Y
Creek 661	661-05	2018	8	impact	before	0.0698	0.0444	3.123	Y

Outliers on log scale:

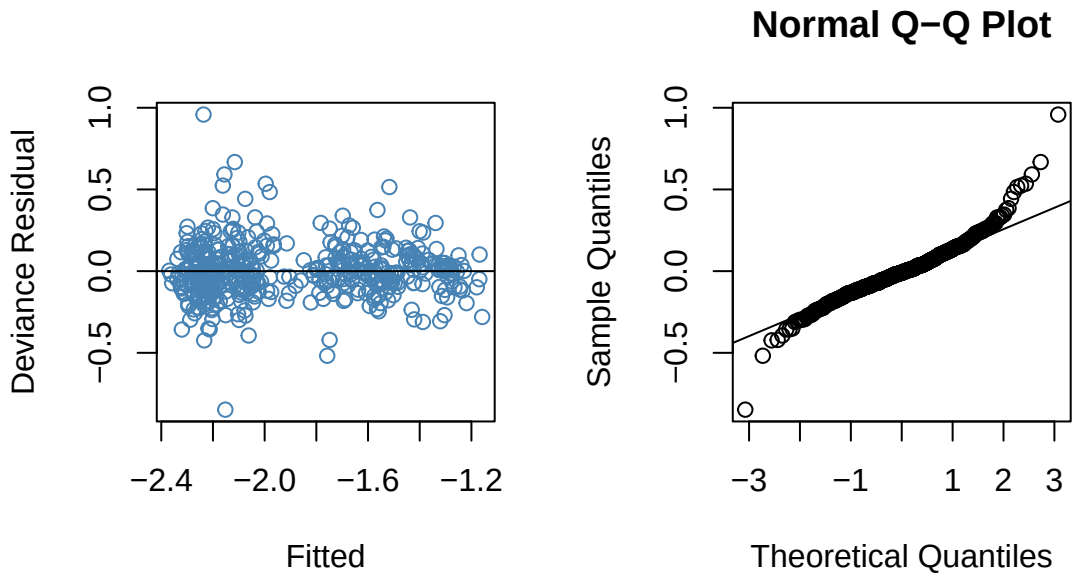
Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Fawnie Creek (Control)	FC-01	2022	6	control	before	-1.278	-2.237	5.709	Y
Creek 661	661-03	2024	10	impact	after	-3.000	-2.152	-5.051	N
Creek 661	661-03	2024	1	impact	after	-1.448	-2.116	3.977	Y
Creek 705 (Control)	705-10	2024	3	control	after	-1.564	-2.156	3.525	Y
Creek 705 (Control)	705-05	2024	3	control	after	-1.461	-1.996	3.186	Y
Fawnie Creek (Control)	FC-01	2023	5	control	after	-1.638	-2.162	3.119	Y
Creek 661	661-10	2017	7	impact	before	-2.276	-1.758	-3.085	Y
Creek 661	661-10	2025	8	impact	after	-1.003	-1.517	3.067	Y

Based on examination of the residuals, the log-10 transformed data were selected for analysis. No outliers were removed prior to analysis.

1.4 Before-After Control-Impact Linear Modeling

A models was fit to compare impact sites with control sites.

Plot of Standardized Residuals and Fitted Values



Results of the ANOVA test on the fixed effects of the model:

	Sum Sq.	Mean Sq.	NumDF	DenDF	F value	p	p adjusted
class	0.2577	0.2577	1	7.015	9.142	0.0192	
period	0.1400	0.1400	1	22.071	4.969	0.0363	
class:period	0.2122	0.2122	1	452.701	7.529	0.0063	0.0104

Results of the observed power calculation for the between-effect test on the fixed effects for repeated-measures ANOVA analysis at a significance level of 0.05:

Sample Size	Effect Size (f2)	Expected Power	Power Test
474	0.7227	100%	Repeated-Measures ANOVA

Summary of BACI contrasts for relative difference between changes from the *before* to *after* in impact sites (661-03, 661-04, 661-05, 661-10, 661-20) and control sites (661-01, 705-05, 705-10, FC-01), with p value adjusted for multiple comparisons:

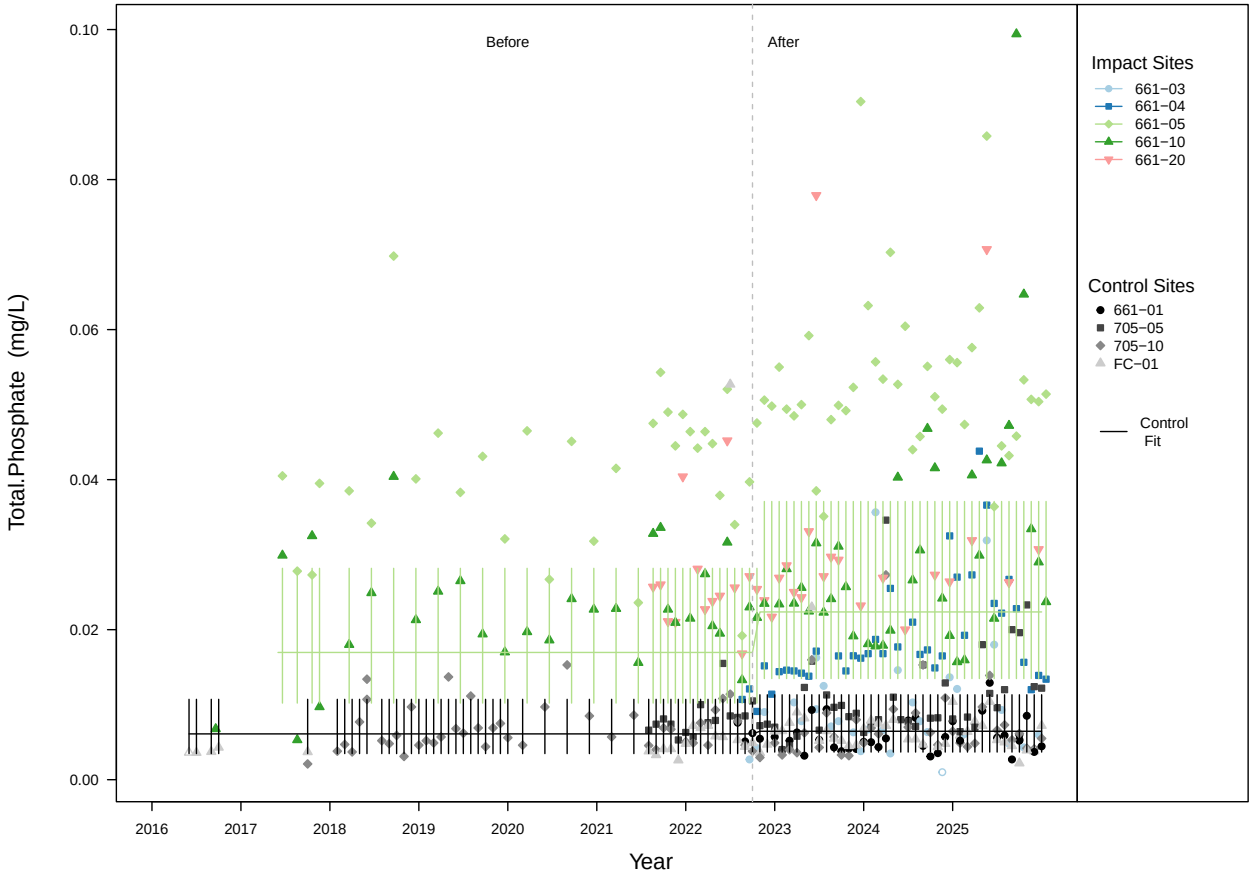
Impact vs.	Estimate	Significance
control sites	0.0958	significant

Conclusion:

The change in Total.Phosphate concentrations at the impact sites from *before* to *after* was significantly (*adjusted p* = 0.0104) different from the change at the control sites, according to the test on the BACI term (*class:period*).

1.5 Model Summary

The overall performance of the model is shown in the plot below. All the observations are plotted along with the model estimates. The model fitted values and 95% confidence intervals are indicated as lines and errors.



Note: Open symbols represent cases where the results were below the sample detection limit. Model fitted values are based on site class and period. Error bars indicate 95% confidence intervals. The positions of data along the x-axis are adjusted for legibility. Modelled log-transformed values were converted back to natural scale.

Final Summary Table

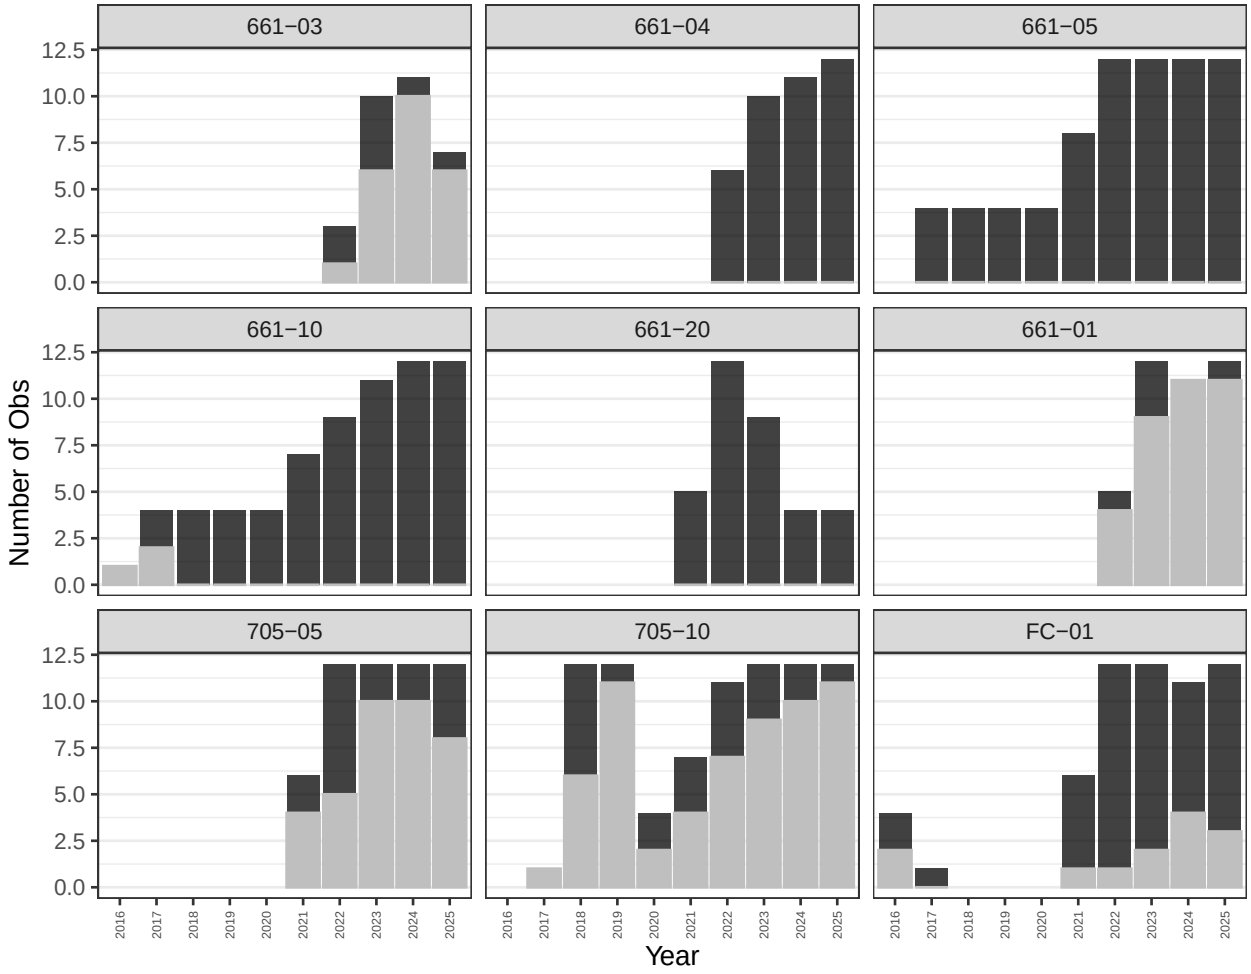
Variable	Total.Phosphate
Watershed	Creek 661
Waterbody	Stream
Streams Removed	None
Data Transformation	Log-10 transformed
Model Type	Linear Mixed Effects Regression
Is BACI significant	Yes

A-12.2.10 Orthophosphate

1 Creek 661

1.1 Censored Data

The following charts indicate the number of measurements taken in each year from each stream that were below the detection limit (light gray) or above the detection limit (dark gray).



Observations at or below the analytical detection limit were considered censored. Data were excluded from the analysis if greater than 70% of observations from a site were censored or if greater than 50% of observations in a site's sampling year were censored. If more than 10% of observations from a site in a sampling year were censored, data were flagged to caution interpretation of results. The following observations were excluded:

Watershed	Site	Year	Class	Period	#Obs Removed
Creek 661	661-10	2016	impact	before	1
Creek 661	661-01	2022	control	before	5
Creek 661	661-01	2022	control	after	5
Creek 661	661-01	2023	control	after	12
Creek 661	661-01	2024	control	after	11
Creek 661	661-01	2025	control	after	12
Creek 705 (Control)	705-05	2021	control	before	6

(Continued on Next Page...)

(continued)

Watershed	Site	Year	Class	Period	#Obs Removed
Creek 705 (Control)	705-05	2023	control	after	12
Creek 705 (Control)	705-05	2024	control	after	12
Creek 705 (Control)	705-05	2025	control	after	12
Creek 705 (Control)	705-10	2017	control	before	1
Creek 705 (Control)	705-10	2019	control	before	12
Creek 705 (Control)	705-10	2021	control	before	7
Creek 705 (Control)	705-10	2022	control	before	11
Creek 705 (Control)	705-10	2022	control	after	11
Creek 705 (Control)	705-10	2023	control	after	12
Creek 705 (Control)	705-10	2024	control	after	12
Creek 705 (Control)	705-10	2025	control	after	12

1.2 Sample Sizes for Modelling

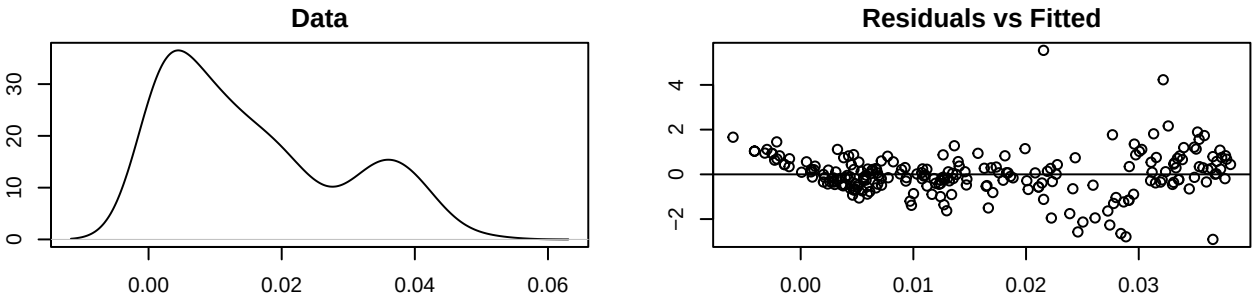
The remaining sample sizes per site and period are summarised in the table below.

Watershed	Site	Period	N	Median	% Censored
Creek 661	661-04	before	3	0.0098	0.00
Creek 661	661-04	after	36	0.0104	0.00
Creek 661	661-05	before	33	0.0315	0.00
Creek 661	661-05	after	39	0.0368	0.00
Creek 661	661-10	before	8	0.0120	0.00
Creek 661	661-20	before	14	0.0158	0.00
Creek 661	661-20	after	20	0.0186	0.00
Creek 705 (Control)	705-10	before	16	0.0014	50.00
Fawnie Creek (Control)	FC-01	before	20	0.0028	20.00
Fawnie Creek (Control)	FC-01	after	38	0.0029	23.68

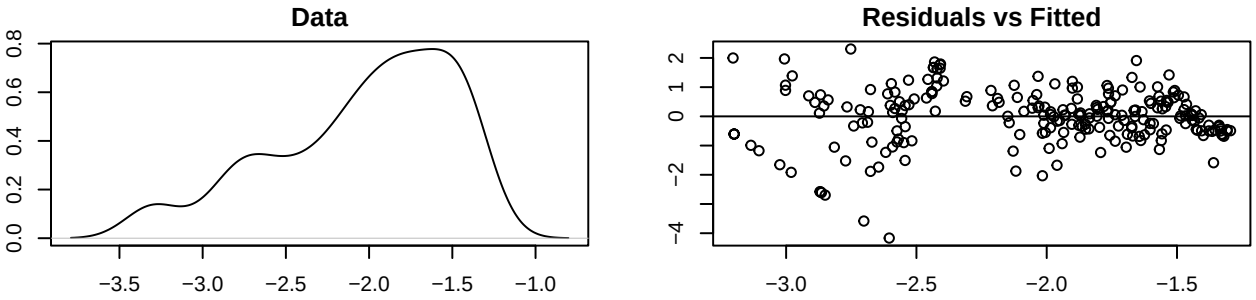
1.3 Initial Model Fit

Initially a model was fit to all sites to assess the need for transformations.

Natural Scale Model



Log−10 Transformed Model



Outliers

The following is a summary of outliers identified (if any) using preliminary regression models. All data points were plotted in the summary figures. The analysis needs to be interpreted with care and in conjunction with graphical displays if large outliers are present.

Outliers on natural scale:

Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Creek 661	661-20	2025	4	impact	after	0.0461	0.0216	5.543	Y
Creek 661	661-05	2018	8	impact	before	0.0509	0.0322	4.229	Y

Outliers on log scale:

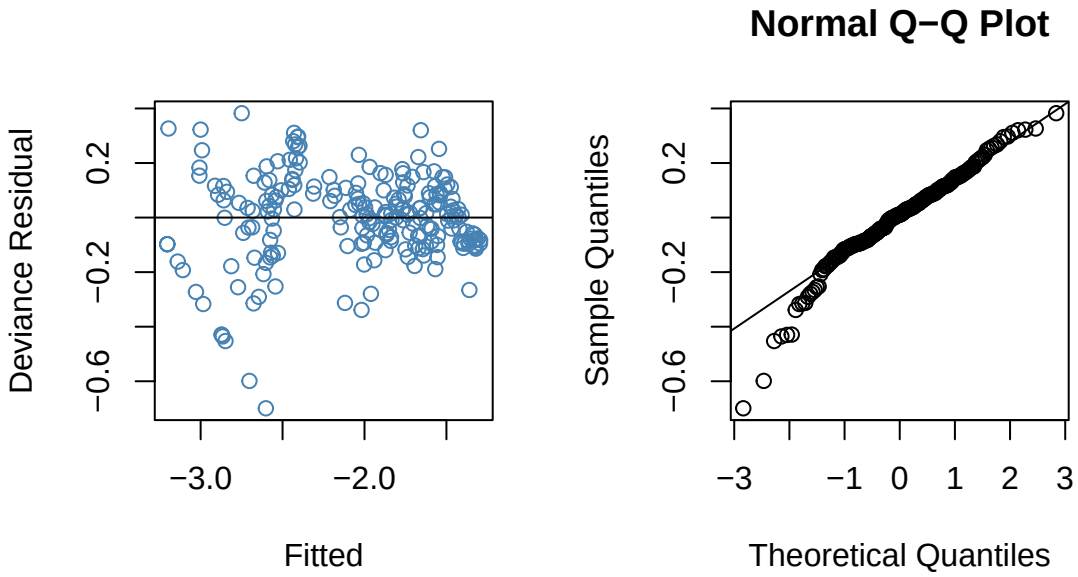
Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Fawnie Creek (Control)	FC-01	2021	12	control	before	-3.301	-2.604	-4.166	N
Fawnie Creek (Control)	FC-01	2024	7	control	after	-3.301	-2.702	-3.583	N

Based on examination of the residuals, the log-10 transformed data were selected for analysis. No outliers were removed prior to analysis.

1.4 Before-After Control-Impact Linear Modeling

A models was fit to compare impact sites with control sites.

Plot of Standardized Residuals and Fitted Values



Results of the ANOVA test on the fixed effects of the model:

	Sum Sq.	Mean Sq.	NumDF	DenDF	F value	p	p adjusted
class	0.41983	0.41983	1	3.008	14.955	0.0304	
period	0.10208	0.10208	1	16.399	3.636	0.0742	
class:period	0.03135	0.03135	1	202.813	1.117	0.2920	0.33

Results of the observed power calculation for the between-effect test on the fixed effects for repeated-measures ANOVA analysis at a significance level of 0.05:

Sample Size	Effect Size (f2)	Expected Power	Power Test
227	1.786	100%	Repeated-Measures ANOVA

Summary of BACI contrasts for relative difference between changes from the *before* to *after* in impact sites (661-04, 661-05, 661-20) and control sites (661-01, 705-05, 705-10, FC-01), with p value adjusted for multiple comparisons:

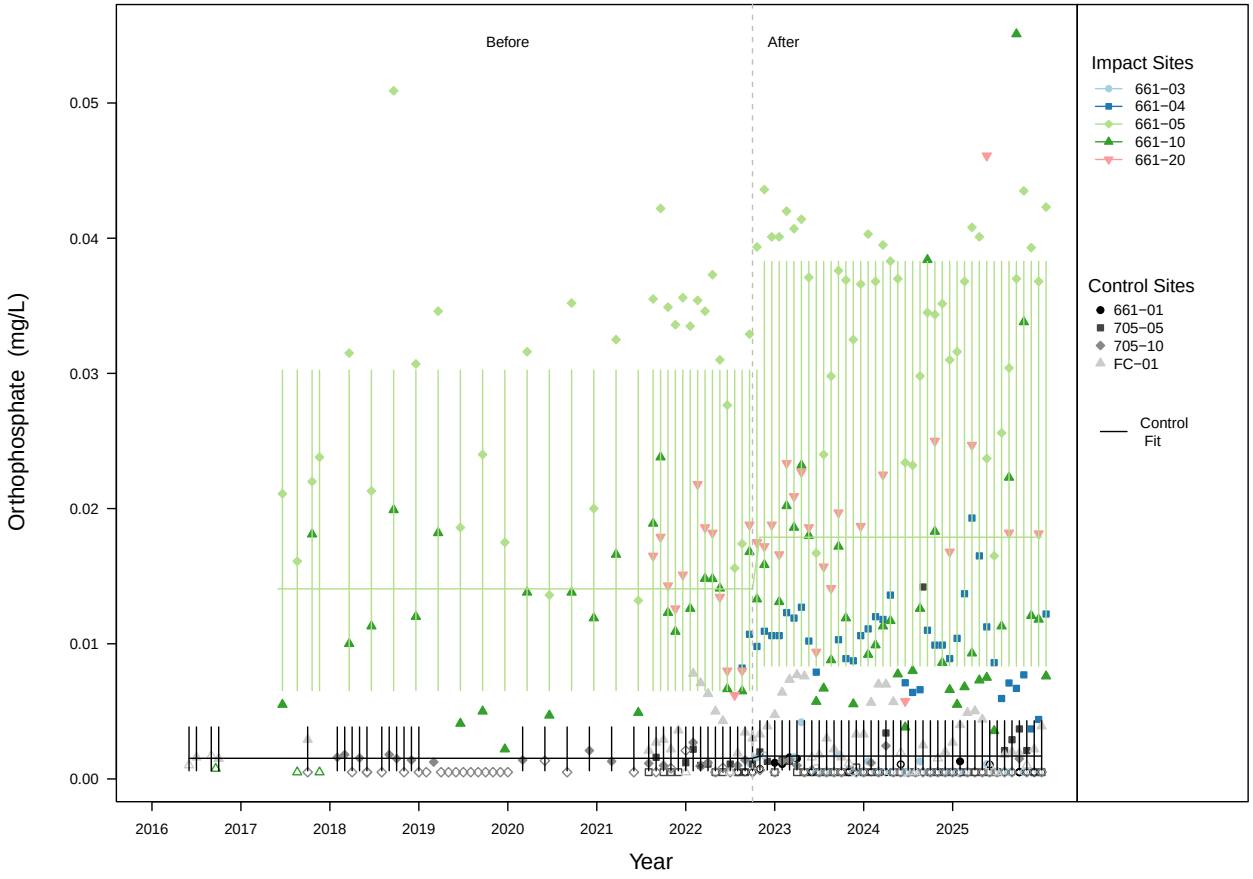
Impact vs.	Estimate	Significance
control sites	0.06	not significant

Conclusion:

The change in Orthophosphate concentrations at the impact sites from *before* to *after* was not significantly (*adjusted p* = 0.33) different from the change at the control sites, according to the test on the BACI term (*class:period*).

1.5 Model Summary

The overall performance of the model is shown in the plot below. All the observations are plotted along with the model estimates. The model fitted values and 95% confidence intervals are indicated as lines and errors.



Note: Open symbols represent cases where the results were below the sample detection limit. Model fitted values are based on site class and period. Error bars indicate 95% confidence intervals. The positions of data along the x-axis are adjusted for legibility. Modelled log-transformed values were converted back to natural scale.

Final Summary Table

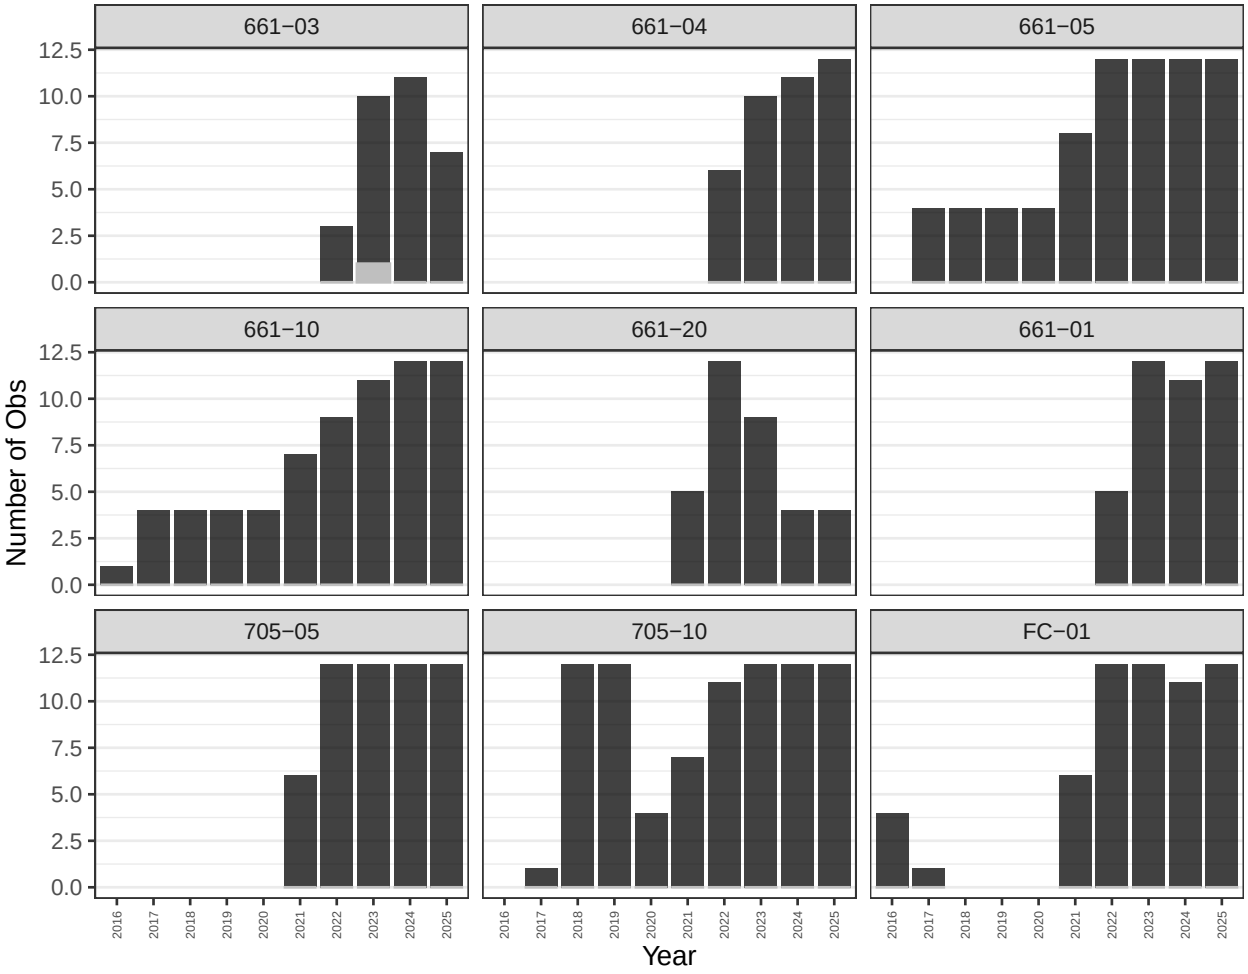
Variable	Orthophosphate
Watershed	Creek 661
Waterbody	Stream
Streams Removed	661-03, 661-03, 661-01, 705-05, 661-10
Data Transformation	Log-10 transformed
Model Type	Linear Mixed Effects Regression
Is BACI significant	No

A-12.2.11 Total Aluminum

1 Creek 661

1.1 Censored Data

The following charts indicate the number of measurements taken in each year from each stream that were below the detection limit (light gray) or above the detection limit (dark gray).



Observations at or below the analytical detection limit were considered censored. Data were excluded from the analysis if greater than 70% of observations from a site were censored or if greater than 50% of observations in a site's sampling year were censored. If more than 10% of observations from a site in a sampling year were censored, data were flagged to caution interpretation of results. The following observations were excluded:

None

1.2 Sample Sizes for Modelling

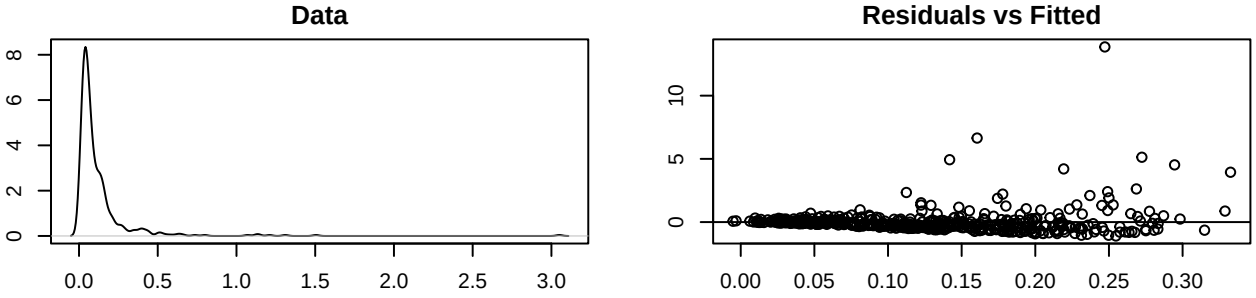
The remaining sample sizes per site and period are summarised in the table below.

Watershed	Site	Period	N	Median	% Censored
Creek 661	661-03	before	2	0.0204	0.000
Creek 661	661-03	after	29	0.0720	3.448
Creek 661	661-04	before	3	0.0510	0.000
Creek 661	661-04	after	36	0.0846	0.000
Creek 661	661-05	before	33	0.0573	0.000
Creek 661	661-05	after	39	0.1030	0.000
Creek 661	661-10	before	31	0.0850	0.000
Creek 661	661-10	after	37	0.1110	0.000
Creek 661	661-20	before	14	0.0464	0.000
Creek 661	661-20	after	20	0.0252	0.000
Creek 661	661-01	before	3	0.0550	0.000
Creek 661	661-01	after	37	0.0581	0.000
Creek 705 (Control)	705-05	before	15	0.0940	0.000
Creek 705 (Control)	705-05	after	39	0.0575	0.000
Creek 705 (Control)	705-10	before	45	0.0944	0.000
Creek 705 (Control)	705-10	after	38	0.0608	0.000
Fawnie Creek (Control)	FC-01	before	20	0.0237	0.000
Fawnie Creek (Control)	FC-01	after	38	0.0172	0.000

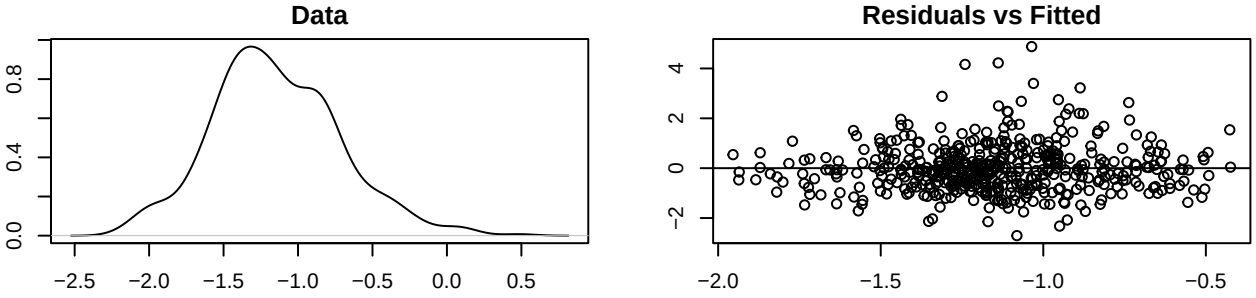
1.3 Initial Model Fit

Initially a model was fit to all sites to assess the need for transformations.

Natural Scale Model



Log−10 Transformed Model



Outliers

The following is a summary of outliers identified (if any) using preliminary regression models. All data points were plotted in the summary figures. The analysis needs to be interpreted with care and in conjunction with graphical displays if large outliers are present.

Outliers on natural scale:

Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Creek 661	661-05	2023	11	impact	after	3.050	0.2472	13.853	Y
Creek 661	661-03	2024	1	impact	after	1.505	0.1605	6.645	Y
Creek 661	661-05	2024	3	impact	after	1.310	0.2724	5.129	Y
Fawnie Creek (Control)	FC-01	2022	6	control	before	1.140	0.1418	4.934	Y
Creek 661	661-05	2025	4	impact	after	1.210	0.2946	4.525	Y
Creek 661	661-04	2025	3	impact	after	1.070	0.2193	4.205	Y
Creek 661	661-05	2024	5	impact	after	1.130	0.3325	3.942	Y

Outliers on log scale:

Watershed	Site	Year	Month	Class	Period	Value	Fitted	Std. Resid	Detected
Creek 661	661-05	2023	11	impact	after	0.4843	-1.0357	4.877	Y
Creek 661	661-03	2024	1	impact	after	0.1775	-1.1386	4.223	Y
Fawnie Creek (Control)	FC-01	2022	6	control	before	0.0569	-1.2405	4.163	Y
Creek 661	661-04	2025	3	impact	after	0.0294	-1.0302	3.400	Y
Creek 661	661-05	2024	3	impact	after	0.1173	-0.8865	3.221	Y

Based on examination of the residuals, the log-10 transformed data were selected for analysis. No outliers were removed prior to analysis.

1.4 Before-After Control-Impact Linear Modeling
